To understand, however, the position of contemporary sculpture in France, it will be necessary to look back even farther than 1870. It must be remembered that the whole history of French sculpture, as far back as the 17th century, is connected with the invasion of Italian influence in the 16th century, which remained paramount over French art for more than three hundred years. Statue-making, until then an art of expression—national, popular, human, and Christian—lost its primitive character under the dilettante refinement of an aristocratic society closely gathered round a king who made art subservient to his splendour or his pleasure; it sank into superficial and conventional beauty, and became almost exclusively the interpreter of trivial ingenuity or flattering allegories derived from the dead fables of heathen mythology. The best that would be expected from this was choice elegance of line, a harmonious treatment of mass and composition, a loving study of the nude—in short, a purely plastic type of art. And sculpture had become the art of the nobility and of the court, having no hold, as it had in the past, on the great human family—the nation. Still, even at the high tide of Louis XIV.'s reign, some dissatisfaction became evident, even some rebellion, in the great though solitary spirit of Puget, who strove to animate the marble with the passions of humanity. In the next century he found followers—Falconet, Pigalle, and Houdon, who also asserted their right to infuse life and passion and movement into their statues, seeking them in the despised province of stern reality. The great cataclysm of the Revolution, which might have been expected to break the bonds of thought, turned men's minds to contemplate the Antique, and though it certainly modified the style of sculpture, was far from changing the source of its inspiration, since it sent it once more to the Antique. Indeed, at the beginning of the 19th century, when the teaching of David was paramount in spite of Gros, who, then in the master's studio, was unconsciously sowing the seed of romanticism in painting, a robust individuality was developing among French sculptors—a spirit somewhat rugged, independent, and partly trained, beyond the academic pale, prepared to carry on the tradition of Puget, and quite simply, without any revolutionary airs of innovation, to shake off torpid conventionality. By the mere force of a strong plebeian temperament Rude quite naturally happened on a style of art—high art—at once expressive and popular. He was the first to raise the cry of liberty in sculpture, and he left successors who bravely worked out what he had begun. Barye and Carpeaux were both in 1875 on the threshold of an era to which they bequeathed a fruitful influence. Barye carried on Rude's tradition of expression, and transformed what had previously been mere decorative carving into a new style and branch of art now adopted by a whole phalanx of admirable artists: the sculpture, namely, of animals, the first glance that sculpture had till then bestowed on nature apart from man. Carpeaux, who was much younger, was in his day—as Puget had been—an exceptional personality; he carried on the slow revolt of two centuries which was to break the narrow mould of school-training and infuse a soul of more ardent vitality into sculptured forms.

The importance of these two great artists in relation to contemporary art was not fully seen till after their death. In point of fact Painting had until now amply filled the new part assigned to Art; its vehement efforts had strongly influenced public opinion; and as, in the early years of the 19th century, it had largely extended the field of human vision over the remote past and the domains of feeling, with the promise of surveying all nature, space, and time, the spirit of the age asked no more, and did not expect sculpture, too, to abandon old-world myths. It must also be said that those sculptors who at that time carried on the classical tradition had renewed its youth by their learned and enthusiastic love of it; they had reverted to the past, but it was the past of the really great masters, either of antiquity or of the early Florentine school, no less enamoured of life, beauty, and nature. Guillaume and Paul Dubois, Chapu and Falguière, Mercié and Delaplanche, were the rivals in sculpture of the great idealist painters—Puvis de Chavannes, Gustave Moreau, Ricard, Delaunay, Baudry, and Henner—who were working at the same time.

This it is which accounts for the fact that romanticism then found so little acceptance among sculptors. But in the next generation the sowers of the seed might see their harvest. The pupils of Rude, of Barye, and of Carpeaux, allied by school sympathies,—the little drawing-school conducted by Lecoq de Boisbaudran, which, in despite of the studios of the Beaux Arts, created a group of independent and highly original artists,—formed the centre of a distinct force which increased day by day. Young men, fresh from Rome, persistently kept up the spirit of the Antique. A galaxy of learned and refined artists

was represented by such men as Hiolle ("Arion," "Orpheus"), Idrac ("Mercury inventing the Caduceus," "Salammbô"), Marqueste ("Galatea," "Eros," "Perseus beheading the Gorgon," "The Rape of Europa"), and Coutan ("Eros," "A Woman carrying Loaves," "A Sergeant-at-Arms," &c.), Lanson ("The Iron Age"), Longepied ("Immortality"), Peinte ("Orpheus charming Cerberus to Sleep"), Gustave Michel ("In a Dream" "Meditation"), Carlès ("Innocence," "Abel"), A. Boucher ("Earth," "Au but"), besides Carlier, Leonard, and Turcan—soon to be followed by another generation: Puech ("The Siren," "The Muse of André Chénier"), Verlet ("The Monument to Maupassant," "Orpheus"), Larche ("The Brook and the Meadow," "Violets"), Sicard ("Hagar and Ishmael"), and Daillon, Escoula, St Lami, and many more. In opposition to these there stood a group of sculptors, young and old, who sought their subjects in mythology, legend, history, or poetry, or merely in the scenes of daily life, and aimed at presenting the ideal of their time under its external aspects, but more especially the deepest emotions of the modern mind. It was Frémiet, with his striking and vivid conceptions, who led the advance with new and dramatic subjects: primeval man and the fierce beasts with which he disputed his rule ("A She-Bear and a Man of the Stone Age," "An Oran-utan and a Savage," "Gorillas"), or embodiments of the heroes of the past ("Joan of Arc," "Saint Louis," "Saint George," "Louis of Orleans," &c.); then followed Just Becquet, the excellent artist who represented the stricken figures of "Ishmaël" and "Saint Sebastian"; Christophe, with his symbolical presentments of "The Human Comedy," "Fortune," and "The Supreme-Kiss"; Aubé ("Monument to Gambetta," "Dante," "Bailly," &c.); A. Legros, the naturalized English painter and sculptor, who executed some fine fountains for the duke of Portland; Injalbert, returned from Rome ("Hippomène," "Christ on the Cross," "The Herald"); and, younger than these, Desbois ("Leda"), Dampt ("A Grandmother's Kiss," "Melusine"), Alexandre Charpentier, Carries, Baffier, Pierre Roche, Madame Marie Cazin, and many more.

The disruption of the Salons in 1890 showed very plainly the bent of this group, who seceded to the Champ de Mars, where the leaders were Dalou and Rodin, and where Bartholomé made an unexpected and original appearance. Foreigners added a contingent of the highest merit, such as the American St Gaudens, and, more especially, the Belgian Constantin Meunier, affiliated to France by their early training, to say nothing of descent. Meunier especially, with his statues and statuettes of labouring figures — miners, puddlers, hammerers, glass-blowers, and the like—gave to his art a keynote new to France, which found a response even in academic circles. A broad democratic current was swaying public feeling. The questions which turn on the status of the working man had become the programme of every party, even of the most conservative. Art being the mirror of society, the novel, the drama, and painting devoted themselves to the glorification of a new factor in modern life, namely, Labour. Sculpture now, in rivalry with painting, through which Millet had immortalized the peasant, and Courbet the working man, also sought inspiration from such themes; and at the same time the demands of the democratic movement called for monuments to the memory and deeds of great or useful men.

Sculpture, under this modern tendency, has assumed an unexpected aspect; its highest expression is seen in the work of three very dissimilar men: Dalou, Rodin, and Bartholomé. In Belgium, as has been said, where modern social questions are strongly felt, Constantin Meunier had interpreted the democratic impulse in a very striking manner, under the influence, no doubt, of J. F. Millet. In France, Jules Dalou, with a broader view, aimed at creating an art which should represent the aspirations and dreams of this phase of society while adhering to the fine old traditions of the art of Louis XIV., stamped with magnificence and grandeur, but applied with graver, simpler, and severer feeling to the glorification of the people. He revived the older style of sculpture, giving it greater power and truer dignity by a close study of life, supported by a scholarly and serious technique. In his "Triumph of the Republic," and the monuments to "Alphand," to "Delacroix," to "Floquet," to "Victor Hugo," and others, he strove to create a style apart from life, to which he is alien and indifferent, but based on life, the outcome of the needs of society, the impersonation of its characteristics, the expression in eloquent form of its nature, spirit, and moral idiosyncrasy.

Treading the same path, though in a different step, is Auguste Rodin. He disregards every contingent fact; even when he takes his subject from legend or history, whether "Eve" or "St John the Baptist," "The Age of Bronze" or "The Burgesses of Calais," "Victor Hugo" or "Balzac," he avoids all the conventional details and attributes of his personages to embody the very essence of humanity as expressed in the quivering flesh. He, like Carpeaux, has gone back to Dante and to Michaël Angelo to force the "Gates of Hell"—the subject chosen for the entrance to the Musée des Arts Décoratifs—and to read the deepest mysteries of the human soul. His is the art of suffering, anguish, and terror, of cruel and despairing pleasure—a wild cycle of proud and bitter melancholy. All the efforts made in the past to infuse life into Art, all that Puget, Falconet, Pigalle, and Houdon tried to effect, and that Rude, Barye, and Carpeaux strove for in their turn—all this was part of the endeavour of these their successors, but with a clearer purpose and more conscious aim. By good hap or providence they were greeted on their way by the voice of the most devoted apostle who was to preach the new doctrine, namely, Louis Courajod, the founder of the French sculpture gallery in the Louvre. From his professor's chair in the schools he cursed the Italian intruders of the 16th century for having debased French art with "noble attitudes," extravagant gestures, and allegorical antics; and he carried his pupils and his hearers back to the great national period of French sculpture, which, in the dark mediæval ages, had created the splendid stone images of the noble French cathedrals.

A marked individuality now appeared in protest against academic traditions—Albert Bartholomé. He, after beginning as a painter, was tempted by sculpture, more particularly, in the first instance, by a wish to execute a monument to a comrade he had loved. From this first effort, carried out in his studio, without any school training, but with a firm determination to master technical difficulties and fulfil his dream, followed a broader purpose to execute a great expressive and vitally human work which should appeal to the heart of the populace. From this arose the idea of a "Monument to the Dead" in Père Lachaise. Bartholomé had started without a guide, but he instinctively turned to the great tradition of Northern Christianity, which his mind subsequently associated with that of the antique race who had ever done most honour to Death, the people of Egypt.

Thus two currents contended, as it were, for the guidance of French sculpture, each claiming a descent from the historic past; one inheriting the classic tradition of the Renaissance, of Latin and Hellenic origin, to which the French school, since the time of Jean Goujon, has owed

three centuries of glory. This is the pagan art of the South; its marks are balance, reasonableness, and lucidity; it was the composer of apotheoses, the preserver of the ideal of beauty. The other, reverting, after centuries of resignation or of impotent rebellion, to the genuine French past which produced the noble works of the 11th, 12th, and 13th centuries,—to the tradition of Flanders and of Burgundy, which was smothered in the 16th century by Italian art,—to the Christian and naturalistic art of the North, which renounced the canons of antiquity, and expressed itself by methods essentially human and mutable, living and suffering,—appeals to all mankind. The immediate result of this antagonism was no doubt a period of agitation. The outcome, on the whole, is confusion. Still, however vexatious the chaos of form and movement may be, it is Life, a true reflection of the tumult of modern thought in its complexity and bewilderment; it is the reawakening of sculpture.

Monumental and decorative statuary found an extended sphere through the founding or restoration of public buildings after the events of 1870. Memorial sculpture obtained constant employment on patriotic or republican monuments erected in various parts of France, and not yet complete. Illustrious masters have done themselves honour in such work. Dalou, Mercié, Barrias, Falguière, and many others less famous executed monuments to the glory of the Republic or in memory of the national defence, and figures of Joan of Arc as a symbol of patriotism, &c., as well as numberless statues erected in the market places of humble towns, or even of villages, in commemoration of national or local celebrities: politicians, soldiers, savants, and artists—Thiers, Gambetta, Jules Ferry, Carnot, Pasteur, Claude Bernard, Delacroix, Ingres, Corot, Millet, Victor Hugo, Lamartine, and many more. The garden of the Luxembourg alone has become a sort of Elysian Fields, where almost every day some fresh statue rises up in memory of contemporary French poets. The funereal style of monument, in which French art was at all times conspicuously distinguished, was also revived in sympathy with that general sentiment which regards reverence for the dead as a religion, and gave rise, as we have seen, to some splendid work by Chapu (the monuments to Regnault, to Daniel Stern, of Mgr Dupanloup); by Paul Dubois (the monument to General Lamoricière); by Mercié (the tombs of Baudry, of Cabanel, of King Louis Philippe and his queen Marie Amélie); by Dalou (the monuments to Victor Noir, to Floquet, and Blanqui); and by many more, with Bartholomé at their head. The cemetery of Père Lachaise is indeed one of the best spots to visit for a review of contemporary sculpture.

While man has been diligently studied in every class of sculpture, more particularly in portrait sculpture, which finds a more practical adaptation to daily uses by a bust or small statue, such as Théodore Rivière was the first to produce, by medallions, or by medals, closely related to statuary, nature now holds a place in the sculpture of animals,—a place created, so to say, by Barye and carried on by Frémiet, Mêne, Caïn, and, with even greater vigour and a closer study of character, by Gardet ("Panthers," in the Luxembourg, "Lions" and "Dogs," at Chantilly, &c.); Peter, Valton, Le Duc, Isidore Bonheur, Peyrol, Cordier, Surand, Virion, Mérite, and others. Finally, the class of *La Petite Sculpture*—the statuette and small group—after long hesitation in the hands of the two men who first cultivated it, Frémiet and the painter Gérôme, made a sudden start into life, due in no small measure to the success attending the charming and pathetic statuettes of Théodore Rivière ("Salammbô and Malthô," "Ultimum feriens," "Charles VI. and Odette," "The Vow," "Fra Angelico," "The Shunamite Woman," &c.). Rivière was wont to use—as Gérôme did in his "Bellona," and subsequently in his small "Tamerlane"—materials of various colours, and even precious stones and metals, which he employed with great effect. A whole class of art was not, indeed, originated, but strongly vivified by this method of treatment. Claudius Marioton and Dampt, who always affected small and precious work, Agathon Léonard (*e.g.*, a table decoration of "Dancers" in Sèvres china), Laporte Blairsy, Ferrary, Levasseur, Belloc, E. Lafont, &c., utilized every process and every kind of material—marble and metal, wood and ivory, enhanced by the most costly goldsmiths' work and gems.

It would seem now that sculpture, thus endowed with new ideas and the most various means of expression, and adapted to every comprehension and every situation, was fully on a level with the other graphic arts. What it had chiefly to fear was, in fact, the wealth of means at its disposal, and its competition or collaboration with other arts. And this the later generations seem to have understood—the men who were the outcome of the two conflicting traditions: order and moderation on one side; character, life, and emotion on the other. Though very variously inspired by the facts or ideals of contemporary life, such young artists as Jean Boucher ("Evening," "The Antique and the Modern"), Roger Bloche ("Childhood," "Cold"), Derré, Boverie, Hippolyte Lefebvre, Desruelles, Gaston Schnegg, Pierre Roche, Fix-Masseau, Couteilhas, and others, seem to show that French sculpture is about to assume a solid position on a sound foundation, while not ceasing to keep in touch with the tastes, aspects, and needs—in short, the ideal—of the day. (L. BE.)

UNITED STATES.

The early names in American sculpture—Shem Drowne, the maker of weather-vanes; Patience Wright; William Rush (1756–1833), carver of figure-heads for ships and portrait sculptor; John Frazer (1790–1850), the stone-cutter; and Hezekiah Augur (1791–1858)—have the interest of chronicle at least. Hiram Powers (1805–73), coming later, had a certain technical skill, and his statues of the "Greek Slave" and "Eve before the Fall" were important agents in overcoming the Puritanic abhorrence of the nude.

Horatio Greenough (1805–52), Joel T. Hart (1810–77), S. V. Clevenger (1812–43), and Clark Mills (1815–83) all received many commissions but made no additions to the advancement of a true art-spirit. Thomas Crawford (1814–57) began the bas-reliefs for the bronze doors of the Capitol and showed skill. They were finished by W. H. Rinehart, whose "Latona" has considerable grace. Henry K. Brown (1814–86) achieved, among less noteworthy works, the heroic Washington in Union Square, New York City. It is one of the noblest of equestrian statues, both in breadth and certainty of handling and in actual majesty. It reflects unwonted credit on its period. There is undeniable skill, which yet lacks the highest qualities, in the work of Thomas Ball (b. 1819), William Wetmore Story (1819–1896), whose "Cleopatra" shows power, Randolph Rogers (1825–1892), J. S. Hartley (b. 1845), Launt Thompson (1833–1894). The works of Olin L. Warner (1844–1896) and J. Q. A. Ward (b. 1830) reveal at times far greater originality. Warner's two graceful classical figures for a fountain in Portland, Oregon, and his portrait statue of William Lloyd Garrison, show a nice discernment of the fitness of manner to matter. He was also successful in modelling medallions. Ward has a sturdiness and individuality quite his own.

But almost all the works down to this time lacked utterly that modernity, that sympathy with the present, which

are in some senses vital to art. American sculpture, like American painting, was awakened by French example. The leading spirit in the new movement was Augustus St Gaudens. Born in Ireland (1848) of Franco-Irish parentage, but brought to America in infancy, at the age of 19 he went to France for three years' study. He must be counted one of the great sculptors of his generation, his perfect technique being the servant of a strong and magnetic personality. In the "Farragut," with its bluff and cheerful grace, the ungainly majesty of "Lincoln," the stern and forceful "Puritan," the monument to Colonel Shaw and his negro troops, and in other statues, he has won the hard victory over modern costume and made it contribute artistic feeling and character. In ideal works, such as the superb mortuary figure called "The Peace of God," decorative caryatids, and the like, he has shown a lofty sense of line and plane. His work in high and low relief is distinguished, notably in his girl with a guitar, the portraits of Stevenson and Bastien-Lepage. In all his works he shows the thorough harmonious welding of treatment with text.

Daniel Chester French has attacked difficult problems with success of the highest order. His "Gallaudet Teaching a Deaf Mute" is an example of how a difficult subject can be turned into a triumph of grace. His "Death and the Young Sculptor" is almost the last word on the beautifying of the idea of death. In collaboration with E. C. Potter he has modelled various important groups of human and animal kind, particularly the "Indian Corn" and the equestrian "Washington."

Frederick MacMonnies stands high among contemporary sculptors by reason of his essentially sculpturesque methods and the magnetic sentiment that imbues them. His "Bacchante" is a triumph of modelling and of joyous humour. Minutely perfect handling and realistic vitality characterize his "Young Pan" and many other works, while his statue of "Nathan Hale" in City Hall Park, New York, shows the artist's power in the treatment of a serious theme, and combines strength, refinement, and lofty feeling.

Modelling in the nude is the test of a sculptor, though almost of necessity anachronistic, but the strenuous achievements of George Grey Barnard have both high skill and high sincerity. His "Two Natures," his "Brotherly Love," his "Pan," and the design for a Norwegian stove are among the strongest of modern statuary. Ranking with him, though different in thought and method, stands Paul Wayland Bartlett—one of the best and most successful of modern sculptors. Success, too, artistically has been accorded to the fine works of Charles Grafly, Herman MacNeil, and Lorado Taft. The beautiful busts of Herbert Adams; the thoroughly artistic miniature figures of Mrs Clio Hinton Bracken; the graceful figurines of Mrs Potter Vonnoh; Edwin F. Elwell's "Egypt" and "Orchid"; and the work of F. Wellington Ruckstuhl, J. Massey Rhind, Frederick Remington, John Donohue, and Charles H. Niehaus should also be mentioned.

(R. HU.)

Scutari, a town of Asia Minor, beautifully situated on the eastern shore of the Bosphorus opposite to Constantinople, of which it is reckoned a suburb. It has a lively trade in Asiatic products. It is built mostly of wood, but on the hills behind the town are many substantial residences. It has a population of about 50,000, mostly Turks. In June 1883 a gunpowder explosion caused the loss of 150 lives.

Scutari, a town of Turkey, in Albania, with a population estimated at 35,000. The trade, both inwards and outwards, has diminished through the connexion of Salonica with the European railway system, but its character has undergone no change. The exports consist of grain, wool, hides and skins, tobacco, and sumach; the imports, of woollen and cotton yarns and piece goods, metals, and sundries. As nothing is done by the Government to develop local resources, the country remains stagnant, and Scutari is a less prosperous and less busy town than it was in 1885.

Sea, Command of the, is a technical term of naval warfare, and indicates a definite strategical condition. The term has been substituted sometimes for the much older "Dominion of the sea" or "Sovereignty of the sea," a legal term expressing a claim, if not a right. It has also been sometimes treated as though it were identical with the rhetorical expression, "Empire of the sea." Mahan, instead of it, uses the term "Control of the sea," which has the merit of precision, and is not likely to be misunderstood or mixed up with a form of words meaning something different. The expression, "Command of the sea," however, in its proper and strategic sense, is so firmly fixed in the language that it would be a hopeless task to try to expel it; and as, no doubt, writers will continue to use it, it must be explained and illustrated. Not only does it differ in meaning from "Dominion or Sovereignty of the sea," it is not even truly derived therefrom, as can be briefly shown. "It has become an uncontested principle of modern international law that the sea, as a general rule, cannot be subjected to appropriation" (W. E. Hall, *Treatise on Internationl Law*, 4th ed. 1895, p. 146). This, however, is quite modern. Great Britain did not admit the principle till 1805; the Russians did not admit it till 1824; and the Americans, and then only tacitly, not till 1894. Most European nations at some time or other have claimed and have exercised rights over some part of the sea, though far outside the now well-recognized "three miles' limit." Venice claimed the Adriatic, and exacted a heavy toll from vessels navigating its northern waters. Genoa and France each claimed portions of the western Mediterranean. Denmark and Sweden claimed to share the Baltic between them. Spain claimed dominion over the Pacific and the Gulf of Mexico, and Portugal over the Indian Ocean and all the Atlantic south of Morocco (Hall, pp. 148–9). The claim which has made the greatest noise in the world is that once maintained by the kings of England to the seas surrounding the British Isles. Like other institutions, the English sovereignty of the sea was, and was admitted to be, beneficent for a long period. Then came the time when it ought to have been abandoned as obsolete; but it was not, and so it led to war. The general conviction of the maritime nations was that the Lord of the Sea would provide for the police of the waters over which he exercised dominion. In rude ages when men, like the ancients, readily "turned themselves to piracy," this was of immense importance to trade; and, far from the right of dominion being disputed by foreigners, it was insisted upon by them and declared to carry with it certain duties. In 1299, not only English merchants, but also "the maritime people of Genoa, Catalonia, Spain, Germany, Zealand, Holland, Frisia, Denmark, Norway, and several other places of the empire" declared that the kings of England had from time immemorial been in "peaceable possession of the sovereign lordship of the seas of England," and had done what was "needful for the maintenance of peace, right, and equity between people of all sorts, whether subjects of another kindgom or not, who pass through those seas" (J. K. Laughton, "Sovereignty of the Sea," *Fortnightly Review*, August 1866). The English sovereignty was not exercised as giving authority to exact toll. All that was demanded in return for keeping the sea safe for peaceful traffic was a salute, enforced no doubt as a formal admission of the right which permitted the (on the whole, at any rate) effective police of

Different from Sovereignty or Dominion, &c.

the waters to be maintained. The Dutch in the 17th century objected to the demand for this salute. It was insisted upon. War ensued; but in the end the Dutch acknowledged by solemn treaties their obligation to render the salute. The time for exacting it, however, was really past. S. R. Gardiner ("The First Dutch War," *Navy Records*, vol. xiii. 1899) maintains that though the "question of the flag" was the occasion, it was not the cause of the war. There was not much, if any, piracy in the English Channel which the king of England was specially called upon to suppress, and if there had been the merchant vessels of the age were generally able to defend themselves, while if they were not their Governments possessed force enough to give them the necessary protection. Great Britain gave up her claim to exact the salute in 1805.

The necessity of the foregoing short account of the "Sovereignty or Dominion of the Seas" will be apparent as soon as we come to the consideration of the first struggle, or rather series of struggles, for the command of the sea. Gaining this was the result of England's wars with the Dutch in the 17th century. At the time of the first Dutch war, 1652–54, and probably of the later wars also, many people, and especially seamen, believed that the conflict was due to a determination on her part to retain, and on that of the Dutch to put an end to, the English sovereignty or dominion. The obstinacy of the Dutch in objecting to pay the old-established mark of respect to the English flag was quite reason enough in the eyes of most Englishmen, and probably of most Dutchmen also, to justify hostilities which other reasons may have rendered inevitable. The remarkable thing about the Dutch wars is that in reality what England gained was the possibility of securing an absolute command of the sea. She came out of the struggle a great, and in a fair way of becoming the greatest, naval power. It is this which prompted Vice-Admiral P. H. Colomb to hold that there are various kinds of command, such as "absolute or assured," "temporary," "with definite ulterior purpose," &c. An explanation that would make all these terms intelligible would be voluminous and is unnecessary here. It will be enough to say that the absolute command—of which, as Colomb tell us, the Anglo-Dutch wars were the most complete example—is nothing but an attribute of the nation whose power on the sea is paramount. It exists and may be visible in time of peace. The command which, as said above, expresses a definite strategical condition is existent only in time of war. It can be easily seen that the former is essential to an empire like the British, the parts of which are bound together by maritime communications. Inability to keep these communications open can have only one result, viz., the loss of the parts with which communication cannot be maintained. Experience of war as well as reason will have made it evident that inability to keep open sea-communications cannot be limited to any single line, because the inability must be due either to incapacity in the direction of hostilities or insufficiency of force. If Great Britain has not force enough to keep open all the communications of her widely extended empire, or if—having force enough—she is too foolish to employ it properly, she does not hold the command of the sea, and the empire must fall if seriously attacked.

Attempts to gain command.

The strategic command of the sea in a particular war or campaign has equal concern for all maritime belligerents. Before seeing what it is, it will be well to learn on high authority what it is not. Mahan says that command, or, to use his own term, "control of the sea, however real, does not imply that an enemy's single ships or small squadrons cannot steal out of port, cannot cross more or less frequented tracts of ocean, make harassing descents upon unprotected points of a long coast-line, or enter blockaded harbours. On the contrary, history has shown that such evasions are always possible, to some extent, to the weaker party, however great the inequality of naval strength" (*Influence of Sea-Power on History*, London 1890, p. 14). The Anglo-French command of the sea in 1854–56, complete as it was, did not enable the Allies to intercept the Russian ships in the north-western Pacific, nor did that held by the Federals in the American Civil War put an early stop to the cruises of the Confederate vessels. What the term really does imply is the power possessed from the first, or gained during hostilities, by one belligerent of carrying out considerable over-sea expeditions at will. In the Russian war just mentioned the Allies had such overwhelmingly superior sea-power that the Russians abandoned to them without a struggle the command of the sea; and the landing in South Africa (1899–1902), more than six thousand miles away, of a large British army without even a threat of interruption on the voyage is another instance of unchallenged command. In wars between great Powers and also between secondary Powers, if nearly equally matched, this absence of challenge is rare. The rule is that the command of the sea has to be won after hostilities begin. To win it the enemy's naval force must be neutralized. It may be driven into his ports and there blockaded or "marked," and thus rendered virtually innocuous; or it must be defeated and destroyed. The latter is the preferable, because the more effective plan. As was perceptible in the Spanish-American war of 1898, as long as one belligerent's fleet is intact or at large the other is reluctant to carry out any considerable expedition over-sea. In fact, the command of the sea has not been secured whilst the enemy continues to have a "fleet in being" (see SEA-POWER).

Strategic command.

In 1782 a greatly superior Franco-Spanish fleet was covering the siege of Gibraltar. Had this fleet succeeded in preventing the revictualling of the fortress the garrison would have been starved into surrender. A British fleet under Lord Howe, though much weaker in numbers, had not been defeated and was still at large. Howe, in spite of the odds against him, managed to get his supply-ships in to the anchorage and to fight a partial action, in which he did the allies as much damage as he received. There has never been a display of higher tactical skill than this operation of Howe's, though, curiously enough, he owes his fame much more to his less meritorious performance on the 1st of June. The revictualling of Gibraltar surpassed even Suffren's feat of the capture of Trincomalee in the same year. In 1798 the French, assuming that a temporary superiority in the Mediterranean had given them a free hand on the water, sent a great expedition to Egypt. Though the army which was carried succeeded in landing there, the covering fleet was destroyed by Nelson at the Nile, and the army itself was eventually forced to surrender. The French had not perceived that, except for a short time and for minor operations, you cannot separate the command of the Mediterranean or of any particular area of water from that of the sea in general. Local command of the sea may enable a belligerent to make a hasty raid, seize a relatively insignificant post, or cut out a vessel; but it will not ensure his being able to effect anything requiring considerable time for its execution, or, in other words, anything likely to have an important influence on the course of the war. If Great Britain has not naval force enough to retain command of the Mediterranean she will certainly not have force enough to retain command of the

Various instances.

English Channel. It can be easily shown why it should be so. In war danger comes less from conditions of locality than from the enemy's power to hurt. Taking up a weak position when confronting an enemy may help him in the exercise of his power, but it does not constitute it. A maritime enemy's power to hurt resides in his fleet. If that can be neutralized his power disappears. It is in the highest degree improbable that Great Britain could attain this end by splitting up her fleet into fragments so as to have a part of it in nearly every quarter in which the enemy may try to do her mischief. The most promising plan—as experience has often proved—is to meet the enemy when he shows himself with a force sufficiently strong to defeat him. The proper station of the British fleet in war should, accordingly, be the nearest possible point to the enemy's force. This was the fundamental principle of Nelson's strategy, and it is as valid now as ever it was.

Seeking the enemy's fleet. If Great Britain succeeds in getting into close proximity to the hostile fleet with an adequate force of her own, her foe cannot obtain command of the sea, or of any part of it, whether that part be the Mediterranean or the English Channel, at any rate until he has defeated her. If he is strong enough to defeat her fleet he obtains the command of the sea in general; and it is for him to decide whether he shall show the effectiveness of that command in the Mediterranean or in the English Channel.

In smaller operations. In the smaller operations of war temporary command of a particular area of water may suffice for the success of an expedition, or at least will permit the execution of the preliminary movements. When the main fleet of a country is at a distance—which it ought not to be except with the object of nearing the opposing fleet—a small hostile expedition may slip across, say the English Channel, throw shells into a coast town or burn a village, and get home again unmolested. Its action would have no sort of influence on the course of the campaign, and would, therefore, be useless. It would also most likely lead to reprisals; and, if this process were repeated, the war would probably degenerate into the antiquated system of "cross-raiding," discarded centuries ago, not at all for reasons of humanity, but because it became certain that war could be more effectually waged in other ways. The Power in command of the sea may resort to raiding to expedite the formal submission of an already defeated enemy, as Russia did when at war with Sweden in 1719; but in such a case the other side cannot retaliate. Temporary command of local waters will also permit of operations rather more considerable than mere raiding attacks; but the duration of these operations must be adjusted to the time available. If the duration of the temporary command is insufficient the operation must fail. It must fail even if the earlier steps have been taken successfully. The command of the English Channel, which Napoleon wished to obtain when maturing his invasion project, was only temporary. It is possible that a reminiscence of what had happened in Egypt caused him to falter at the last; and that, quite independently of the proceedings of Villeneuve, he hesitated to risk a second battle of the Nile and the loss of a second army. It may have been this which justified his later statement that he did not really mean to invade England. In any case, the British practice of fixing the station of their fleet wherever that of the enemy was, would have seriously shortened the duration of his command of the English Channel, even if it had allowed it to be won at all. Moreover, attempts to carry out a great operation of war against time as well as against the efforts of the enemy to prevent it are in the highest degree perilous.

In war the British navy has three prominent duties to discharge. It has to protect the maritime trade, to keep open the communications between the different parts of the empire, and to prevent invasion. If Great Britain commands the sea these duties will be discharged effectually. As long as she does that, the career of cruisers sent to prey on her commerce will be precarious, because command of the sea carries with it the necessity of possessing an ample cruiser force. As long as the condition mentioned is satisfied her ocean communications will be kept open, because an inferior enemy, who cannot obtain the command required, will be too much occupied in seeing to his own safety to be able to interfere seriously with that of any part of the British empire. This being so, it is evident that the greater operation of invasion cannot be attempted, much less carried to a successful termination, by the side which cannot make head against the opposing fleet. Command of the sea is the indispensable preliminary condition of a successful military expedition sent across the water. It enables the nation which possesses it to attack its foes where it pleases and where they seem to be most vulnerable. At the same time it gives to its possessor security against serious counter-attacks, and affords to his maritime commerce the most efficient protection that can be devised. It is, in fact, the main object of naval warfare.

Authorities for the above may be given as naval histories in general, placing in the first rank the well-known works of Captain A. T. MAHAN, U.S.N. The book which must be specially referred to is the late Vice-Admiral P. H. COLOMB's *Naval Warfare*, 3rd ed., London, 1900. (C. A. G. B.)

Sea-fishing.—Sea-fishing as a sport is a comparatively modern institution. Many years ago a few amateurs might be found following the methods of the professional, laying long-lines, using coarse hand-lines, even netting on occasions, and whiffing and working drift-lines for pollack and bass. But it was not until the last few years of the 19th century that any considerable number of persons attempted to catch fish with the more refined and delicate methods, or modifications of them, practised on rivers and lakes. Several volumes on the subject were published between the years 1897 and 1900, and this diffusion of information, coupled with a serious falling-off of sport in many fresh-water fisheries, induced large numbers of anglers to look to the sea for the practice of their favourite recreation, and laid the foundation of the British Sea-Anglers' Society, which soon numbered very nearly a thousand members. *British Sea-Anglers' Society.* The absence of private rights in sea-fisheries renders the sea an appropriate fishing-ground for the general public. Even in navigable estuaries such rights do not exist, save where a charter from the Crown was granted in ancient times.

Sea-fishing as a sport, as we now understand it, is mainly concerned with the use of a rod and line in the sea, though for the heavier work with big bottom-swimming fish, such as the conger, the stronger and coarser hand-line is under certain conditions still deemed necessary by some fishermen. Probably the finest sea-fishing which has yet been discovered by the enthusiastic angler is that afforded by the tarpon, or silver king, of the Gulf of Mexico, a gigantic herring which often exceeds 100 ℔ in weight, and fights with demoniacal fury when hooked. *Tarpon and tunny.* So favourite a form of sea-fishing has this become that tarpon hotels have sprung up on the coast of Florida, and not a few Englishmen journey across the Atlantic from time to time to take part in this exciting sport. The bait commonly used is a small mullet threaded on a large hook attached to an unleaded line. It is cast out from a boat and allowed to

lie on the bottom. When the tarpon picks it up, time is allowed for the bait to be gorged, as the mouth of these fish is extremely hard and bony, and affords scant holding-place for the hook. Another kind of big fish angling afforded by American waters is tunny-fishing, which is carried on by the members of the Flying Tuna Club, of Avalon, Santa Catalina Island, who think little of capturing fish weighing considerably over 200 ℔. Tunnies and other big members of the mackerel family are also caught from ocean-going vessels. Sharks have been taken from time immemorial in tropical waters, and the capture of specimens 5 and 6 feet in length, on British coasts, is not uncommon; but, generally speaking, the sea-angler desires to avoid rather than to capture them. The coasts of Australia, Africa, India, and the tropical seas generally all afford excellent sea-fishing of various kinds in due season.

The bass.

In British and Irish waters the fish which holds the highest place in the angler's list is undoubtedly the bass, which will take fly, spinning, or indeed almost any bait, and when hooked is as game as salmon. To capture the very large specimens of these fish, and such captures are not common, it is desirable to fish at night, or in the dusk of early morning. In the daytime success is not often obtained unless the water is slightly thickened by recent gales. The big fish particularly favour the mouths of harbours, where they may be caught on such malodorous baits as a stale piece of bloater, a piece of ray's liver, small dead fish, chicken's or rabbit's entrails, &c. They have the habit, either acquired in such places, or natural to them, of foul feeding. Sometimes the bait intended for bass is worked round the edges of rocks by means of float-tackle much the same as pike-fishers use, except that it terminates in a large, strong, single hook instead of the usual triangles. A better plan, where the bottom is clear, is to use a salmon-gut ledger with a lead of sufficient weight to hold the bottom. Medium-sized bass of from 2 to 5 ℔ are found in shoals during the late summer months, and when these are feeding close to the surface on the young of other fish—herrings, sprats, mackerel, &c.—the fly-fisher has an opportunity of enjoying some very excellent sport. The gaudier salmon-flies will take bass, but a piece of dried sole-skin, cut in the shape of a fish and whipped to a hook, is frequently used for the purpose. Baits such as sand-eels, or other small fish, are often trailed behind a boat, but they are better harled across the tidal current in the manner practised on salmon rivers. Perhaps the most deadly method of taking bass is to use a live fish on a drift line, two of the best baits being a sand-eel and a small flat-fish. The hook is attached to a snood several fathoms in length, above which are placed small pipe-leads at intervals of one and a half to two fathoms. The tide carries out the bait, and a sufficient amount of the lead-bearing line is let out to ensure the bait being at a proper depth. In this method, which is most suitable for estuaries and channels between islands where there is a fairly good tide running, the boat should be moored.

Pollack and coal-fish.

Pollack and coal-fish, termed lythe and saithe in Scotland, rank next after bass as sport-giving sea-fish, and are far easier of capture. Pollack lurk among rocks and weeds, coming to the surface in the evening in search of food. Rocky points projecting far out into the sea are certain places to find them. One of the best baits is a small conger-eel about 4 inches in length, trailed behind a boat. Failing this, the rubber imitation may be tried. Sand-eels are also very good. In fact, pollack, when feeding, will run at almost any small fish. In the daytime the line should be heavily leaded to bring the bait down close to the weeds. In the evening the sea-angler fishes near the surface. Pollack will also take the usual pike spinning-baits, phantoms (red for preference), spoons, and the like. Live-baiting for them is carried on in exactly the same manner as for bass, and is suitable in places where the boat can be moored over a rocky ground in a current sufficient to extend the drift-line. The tackle has to be exceedingly strong, as these fish have a habit of darting down into the weeds when hooked, and must in consequence be given no line. Coal-fish, which have many local names, are somewhat similar in form to pollack, but differ in colour, the beautiful olive, bronze, and brown tints of the pollack giving way to a very dark greeny blue back and white sides and belly. They are freer swimming fish than pollack, roaming in shoals in search of food, and at times affording very fine sport. They will take all the usual pollack and bass baits, and in the North they are often fished for with rough feather baits, from 2 to 4 inches in length. On the Irish coast the fishermen catch large numbers of medium-sized coal-fish, called, locally, "glissaunes," by trailing flies, the lines being attached to long bamboo poles projecting from the stern of sailing boats. For pollack, coal-fish, and bass, ordinary salmon and pike rods furnished with strong lines can be used, except for the method of drift-lining, the special tackle for which has been described.

Grey mullet.

Grey mullet are much sought after by sea-anglers, but are extremely difficult of capture owing to their shyness and to their peculiar mouths, which are apparently formed to suck in very soft food, and to eject quickly anything hard, such as a hook. The very large grey mullet are, indeed, rarely caught on hook and line; but the bass fisher, using ray's liver or similar bait at the mouth of a harbour, sometimes obtains a specimen. During the summer months these fish run up rivers, and at night-time forage along the shore near towns, doubtless attracted there by the refuse. The smaller mullet of 1 or 2 ℔ are caught in large numbers in docks, harbours, and at the mouths of rivers on the south coast, on a stout perch paternoster baited with rag-worms; but, generally speaking, success is only obtained by those who are on the water a little before daybreak. There are a few creeks round English coasts where large mullet are often seen. In such places an attempt may be made to catch them, their suspicions being lulled by the throwing in of ground-bait of a similar character to that on the hook. For this purpose boiled macaroni, chopped up, may be tried. The tackle may be a paternoster bearing several hooks supported by a float, and allowed to swim down at whatever speed the current will take it. Mullet, however, are more likely to feed just at the top of high water when the tide is slack. If this tackle is drawn against the tide, or held in an unnatural way against it, the fish are likely to ignore the baits. This, however, does not apply to paternostering with rag-worms for the small mullet in harbours and river mouths where a sink-and-draw motion is often given to the baits. A method of mullet-fishing which is occasionally successful is to float the paternoster, without a lead, on the surface of the water by means of small fragments of cork placed at intervals, and to bait the hooks with macaroni or paste. Bread crumbs are sprinkled on the surface near the tackle to bring up the fish. The angler should keep himself at a considerable distance from the baits, out of sight of the fish.

Mackerel-ing.

Mackerel-fishing is, as a rule, carried on in much the same way by amateurs as by the professional fishermen, many of these latter having adopted the use of gut snoods with excellent results. When, however, the wind is very slight and the day bright, the amateur often catches mackerel by using still finer tackle

and very small lead, the professional fisherman's gear being absolutely useless under such conditions. In late summer, when the mackerel are inshore on some parts of the coasts, a very pretty method of capturing them is to moor the boat and use float-tackle, the float being about 10 feet or less above the bait—a strip of mackerel skin. This arrangement is carried out by the tide about 20 yards, the moving tide working the bait and giving it a lifelike appearance. If the current is very slight it is sometimes better to dispense with both float and lead, and fish by touch. Mackerel are also to be caught near the bottom on some parts of the coast towards the end of summer and in early autumn. The best baits are squid, pilchard skin, mussels, and pieces of sand-eels. The tackle may be the ordinary paternoster, or a paternoster in which the plummet at the end is dispensed with, a pipe-lead placed where the running line joins the gut taking its place. Mackerel, when near the surface, will take a fly, but when they are shoaling inshore, breaking the surface every now and again, it is difficult to keep within casting distance of them. The fly-fisher, however, sometimes obtains good sport with these fish when they have collected in narrow and shallow inlets of the sea. The best time of the day for mackerel-fishing is from six o'clock in the morning, or even earlier, to 11 A.M.

It is when fishing on the bottom for cod, conger, whiting, flat-fish, gurnet, &c., with heavy leads, that special forms of tackle are most requisite. The ordinary pike-rod 11 feet long is no use for working a tackle bearing a weight of $1\frac{1}{2}$ lb to 2 lb. The rings fray the line, and the leverage on the wrist, owing to the length of the rod, is enormous. The reels of freshwater fishermen are too small for this purpose. Very excellent sea-rods have, however, been designed by anglers and tacklemakers. These vary from 6 feet to 8 feet in length, are stout and strong, frequently have a spliced whalebone top, and in the place of rings are fitted small sheaves working between metal supports. At the end of the rod are various forms of blocks, none, however, being more satisfactory than the ordinary block used by sailors, but, of course, very much reduced in size. Large reels of the Nottingham type, made of non-corrosive material, 6 inches and even 7 inches in diameter, are used. These will easily hold 200 yards of line, and by reason of their large diameter wind up as quickly as a hand-line can be hauled in. A modern innovation is the use of plaited wire lines. These have great strength, are fine, and do not hold the water; but they are apt to kink and break unless very carefully used. The ordinary hemp or silk line for sea-fishing should be tanned with catechu.

The modern sea-rod.

The most generally useful form of tackle for fishing on or near the bottom is the paternoster, which may be of single twisted gut or gimp, according to the fish which are being sought after. Far better than the ledger for fishing from a boat is a paternoster with the last link extended to 2 feet or a little more, and bearing two hooks which will lie on the bottom if the lead is lowered to a sufficient depth. Over weeds or rocks this tackle can be kept a foot or two from the bottom, and is very generally useful. Leads should be provided of various sizes, the angler always using the lightest which will hold the bottom, increasing its weight as the tide strengthens, decreasing it as the tide slackens. The heavier the lead the more difficult it is to feel the bites of the fish. The eyed hooks of good quality used by freshwater fishermen have largely taken the place of the old flatted, tinned hooks of the professional sea-fisherman. In conger-fishing amateurs usually mount their hooks on gimp, but a soft snood of plaited hemp or flax is better. The best conger and bream fishing is at night. When paternostering on the bottom, and the tidal current is slight, it may be found necessary to use small wire booms 3 inches or 4 inches in length to extend the hook-links from the vertical portion of the paternoster, which they might otherwise foul. A swivel to keep the line from kinking and one at the end of each boom are useful. Among the best baits for fishing on or near the bottom are lug-worms, mussels, sand-worms, rag-worms, shrimps, prawns, oysters, squid, cuttle-fish, pilchard, herring, sprat, mackerel, hermit-crab, and soft-crab.

Advantages of the paternoster.

Seaford, a parish, railway station, and watering-place, Sussex, England, in the Eastbourne parliamentary division of the county, 13 miles east of Brighton. Its ancient corporation was dissolved in 1886, and it is now governed by an urban district council. A parade was built in 1881–82, and in 1887 a concrete groyne. In 1896 Queen's Hall was built, a church institute was founded in 1898, and in 1897 a cemetery of 5 acres was opened. There are golf links extending for about 3 miles. The population of the urban district in 1891 was 1991; in 1901, 3355.

Seaham Harbour, a parish, urban district (1894), and seaport town, Durham, England, in the South-Eastern parliamentary division of the county, 6 miles south of Sunderland by rail. Besides the coal trade there are extensive bottle works, and electrozone works. The population of the urban district was in 1891, 9044; in 1901, 10,163.

Seal.—The fur seals or "sea bears" and sea lions (*Otariidæ*), with the walruses, constituting the sub-order Gressigrada, are closely related to the bears, and are very distinct from the true or hair seal (*Phocidæ*), with which they have been more or less confused. Of the two groups or genera of fur seals, *Arctocephalus* (*A. townsendi*, Guadalupe Island; *A. philippii*, Galapagos Islands; *A. australis*, southern coasts of South America and neighbouring islands; *A. delalandii*, islands and coasts of South Africa; *A. gazella*, Kerguelen and Prince Edward Islands; *A. forsteri*, coasts of New Zealand and South-Western Australia) was once widely distributed over the pelagic islands of the southern hemisphere, but is now practically extinct in the greater part of its habitat. Remnants of importance exist only on Lobos Island in the mouth of the river Plata in Uruguay, and on the islands off Cape Horn; both of these now receive protection from Government. The other genus, *Callorhinus* (*C. ursinus*, Commander Islands; *C. alaskanus*, Pribiloff Islands, both in Bering Sea; *C. kurilensis*, Robben Island and Kurile Islands, Sea of Okhotsk), is limited to the waters of the North Pacific Ocean.

Of the southern herds little authentic information exists, but the records for the northern herds are fairly complete. At the period of its maximum development, 1870 to 1880, the herd of the Pribiloff Islands numbered about $2\frac{1}{2}$ million animals; that of the Commander Islands about one-half as many. The third herd is one of minor importance, numbering in 1897 less than 1000 animals on Robben Island. All three herds became greatly reduced, and in 1896–97 numbered in all not more than 600,000 animals. The typical adult male or bull (*sikatch*) attains maturity about the seventh year, and weighs from 400 to 500 lb. He is 6 feet in length, with a girth of $4\frac{1}{2}$ feet. His fur is blackish or dark brown, with long yellowish-

white water hairs, especially long and firm on the back of the neck, forming the so-called "wig" or mane. The fore limbs, or flippers, are modified as oars and used in swimming. The animal stands erect and runs or lopes along the ground when on land. The adult female, or cow (*matka*), is much smaller, averaging about 80 ℔ in weight, with length and girth in proportion. Her fur is of varying shades of brown. She bears her first young at the age of three years.

The breeding-grounds are boulder-strewn beaches or rocky hill slopes near the shore. On these the gregarious instinct of the animals leads them to congregate in close-set masses called rookeries. The unit of rookery life is the family group, or harem, each bull getting about him as many females as he can control. The number ranges from 1 to 100 or more, averaging about 30. The bulls reach the islands early in May and take up their places. The cows begin to arrive the first week in June. The number on the rookeries from day to day grows steadily to a climax about the middle of July, when about one-half are present, the number actually on the ground diminishing to about one-fourth at and after the close of the breeding season with the end of July. The single young, or pup (*kotik*), weighing 10 to 12 ℔ and jet black in colour, is born within six to forty-eight hours after the arrival of the cow. Within a week the latter is served by the bull, and by the end of another week she goes to sea to feed, returning at gradually lengthening intervals through the summer to nourish her young, left in the meantime to care for itself on the rookeries. The bulls, having fasted since their arrival in May, go away in August to feed. The pups learn to swim at the age of a month or six weeks, and in November, with the approach of winter, they swim away with their mothers to the south. The winter migration of the Pribiloff seals extends as far south as the latitude of southern California, the return course following the coast. The Commander seals reach the latitude of southern Japan and return on their course. The fur seals find their food, chiefly squid (*Gonatus amœnus*), the Alaska pollack (*Theragra chalcogramma*), and especially a small smelt-like fish (*Therobromus callorhini*), in deep water, and their feeding-grounds in Bering Sea and on the migrations lie mainly along the 100-fathom curve.

The Commander Islands were discovered by Vitus Bering in 1741, and our first knowledge of the northern fur seal herds comes from the notes of Georg Wilhelm Steller, a German naturalist accompanying Bering's expedition. The Pribiloff Islands were discovered in 1786, and were transferred with the territory of Alaska to the possession of the United States in 1867. The Russians, in their half-century or more of experience with the fur seals, worked out the principle, based on the polygamous habit of the animals, of affording absolute protection to the breeding female herd, and confining the killing to the superfluous males. This principle is still rigidly adhered to in the operations of land killing. The young males, or bachelors, haul out to rest and sleep on beaches adjacent to, but distinct from, the breeding-grounds. Here they are surrounded at night by the sealing gangs (natives from the Aleutian Islands, brought over by the Russians to carry on the sealing operations), rounded up in droves of from 1000 to 3000, and driven inland to the killing-grounds. The large droves are broken up into successive "pods," or groups, of from 20 to 50, of which the "killable" seals (animals of three years of age or approximating to such in size) are knocked down with clubs, those too large or too small being allowed to escape. The skins are removed, salted in kenches, and, when cured, shipped to London, where practically all the fur sealskins of the world are dressed. The two important processes in dressing the skins are the removal of the long water hairs which grow out through the short thick fur, and the dyeing of the fur itself black—both delicate and difficult operations.

The decline already noted in the fur seal herds of Bering Sea is due to the growth of a rival sealing industry—the hunting of the animals at sea with spear or shotgun, now known as pelagic sealing. Stragglers from the migrating herd had from the earliest times been taken by the Indians of Cape Flattery and Vancouver Island, going out from the shore in their canoes, but the number so captured was small. In 1879, however, sailing vessels began to be used to carry the hunters and their canoes out to the main body of the herd, and to enable them to follow its movements. The industry developed rapidly, by 1892 employing a fleet of 122 sailing vessels, each with from five to twenty hunting crews. The catch at sea grew to a maximum in 1894 of 140,000 skins. The operations of the fleet gradually extended to cover the entire migration route of the herd, and in 1883 the sealers entered its summer feeding-grounds in Bering Sea. Pelagic hunting, necessarily indiscriminate, affected most seriously the herd of breeding females. Investigations carried on in Bering Sea in 1895 and 1896 show that from 62 to 84 per cent. of the pelagic catch are of this class, the death of the female involving the death of her unborn offspring, as well as that of the unweaned young.

Under sanction of a claim made by Russia in 1821 to exclusive jurisdiction in Bering Sea, a claim decided by the Paris Tribunal of 1893 to be untenable, the United States in 1886 seized sealing vessels operating in that sea—among them Canadian vessels. This brought on a diplomatic discussion with Great Britain, which culminated in 1892 in a treaty by which it was agreed to submit to a court of arbitration the claims of the United States to jurisdiction in Bering Sea in the interests of her fur seal herd when beyond the ordinary territorial limits. The Tribunal of Arbitration met in Paris in 1893. Its decision was adverse to the contentions of the United States, and equally adverse to the life of the fur seal herds. As agreed upon in such event, the tribunal formulated a set of rules for the regulation of pelagic sealing, with a view to the protection of the seals. These regulations provided for a close season in May, June, and July, and a protected zone of 60 miles' radius about the breeding islands. The regulations failed utterly of their object, because the breeding females do not feed within the protected area, but far outside of it, and are therefore taken without restriction on the feeding-grounds in August and September, their young being left to starve.

In 1896, with a view to a revision of the regulations, it was agreed between the United States and Great Britain that a new investigation of the facts of seal life should be made. At the close of this inquiry in 1897 the two Commissions met in Washington as a Joint Conference of Fur Seal Experts, and after a discussion of the results of their labours, a substantial agreement was reached on all essential facts. On the basis of this agreement the fur seal question passed into the hands of a Joint High Commission, representing Great Britain, the United States, and Canada, called at Quebec in September 1898 to consider a number of questions at issue between the United States and Canada. There the matter rested. Meanwhile the herds have continued to decline, and the pelagic catch has itself fallen off rapidly with the depleted herds.

For a full discussion of the fur seals and fur seal industries reference should be made to the reports of D'Arcy W. Thompson, Commissioner for Great Britain, and his associates, for 1896 and 1897 (*Parliamentary Papers*, "United States," No. 3 (1897), and No. 1 (1898)), and especially to the elaborate final report of David S. Jordan, Commissioner for the United States, and his associates,

for the same years (*Treasury Department Document*, No. 2017, "Fur Seals and Fur Seal Islands of North Pacific Ocean," 4 vols. and atlas. Washington, 1898). Other papers of importance are: Henry W. Elliott's "Monograph of the Seal Islands of Alaska," Bull. 147, *U.S. Fish Commission*, 1882, and the report of C. Hart Merriam and Thomas C. Mendenhall, the American Commissioners for 1891, *Proc. Paris Arb.* vol. ii. pp. 311–396.

The table herewith appended gives the statistics, so far as available, of the fur seal herds as represented by the product taken on land and at sea. The records prior to 1870 are more or less unsatisfactory, but those subsequent to that date are authentic :—

Seamanship.—The art of seamanship consists in causing a vessel to contend successfully with wind and with sea. The modern development of steam engines and the employment of steel in the construction of the hulls have created a further demand for punctuality and comfort in the performance of voyages, and have resulted in a great increase in the size of vessels for all but mere coasting and fishing purposes. The tendency of this demand, coupled with inter-oceanic thoroughfares of communication, such as the Suez Canal, has constantly lessened the proportion of vessels propelled by sails to that of machine-propelled steamers, capable of attaining the habitual punctuality of the present day. In the United Kingdom, in the middle of the 'seventies, 132 steam-vessels of wood or of iron were in process of construction, and 317 sailing vessels of the same materials. In the latter part of 1898, 533 steamers of steel, iron, and wood were being built, and only 25 sailing vessels of greater size than 100 tons; in that year 646 steamers were completed and added to the mercantile marine of the United Kingdom, and 195 were either lost or broken up; 242 sailing vessels, mostly small, were added, and 448 were wrecked or destroyed. Thus the steam navy has largely increased, and the sailing navy is rapidly dwindling. The same qualities in the seaman that led to national success in the era of sails are now required for corresponding efficiency under the stringent requirement of forcing passages in all weathers and at all seasons. In modern ships the demands on the human endurance of executive officers, and of engineers and their subordinates, are greater and more prolonged than on those of a rapidly passing generation; for while it may be granted that during heavy weather, and specially in narrow waters, severe strain is brought on the seamanship of officers and crews of sailing vessels, long interludes of moderate and calm weather afford periods of comparative relief. But in these days of almost universal steam-power, the hurry and drive of making rapid passages last without cessation from port to port. If we gauge the distances traversed by modern steamers by immunity from accident, as compared with the lesser distances covered by the sailing vessel, between year's end and year's end, the percentage of calamitous accidents has greatly diminished, for the men who follow the sea have developed qualities of seamanship suitable to the mechanical necessities of their time.

Seamen, Merchant.—Since the article on LAWS RELATING TO SEAMEN (*Encyclopædia Britannica*, 9th edition, vol. xxi. p. 605) was written, a reform therein indicated as urgently required has been effected. The law had at that date to be gathered from the Merchant Shipping Act, 1854, and a long series of amending Acts. Further amending Acts were passed until 1894, but in that year the whole of the existing merchant shipping Acts were repealed and consolidated in one statute, the Merchant Shipping Act, 1894. To that Act, and especially to Part II., which deals with masters and seamen, and Part V., which deals with safety, and not to the repealed Acts mentioned in the article, reference must now be made. With some modifications which are indicated below, the law is substantially as stated in the previous article, and it will here only be necessary to call attention to recent changes, and in some respects to amplify the earlier statement.

The law as to the engagement and discharge of seamen has not been altered. But it should be pointed out that these must take place before a superintendent only when the employment is on a foreign-going ship. If the ship is a home-trade ship, the signing on and discharge take place before a superintendent only if the master so desire. But if the signing on does not take place before a superintendent, the master must cause the agreement to be read and explained to the seaman, and the seaman must sign it in the presence of a witness; copies of all such agreements must be transmitted to the proper Board of Trade officials. A copy of every agreement with the crew must be posted up in some part of the ship which is accessible to the crew. In any British possession abroad other than that in which the ship is registered, a seaman must be engaged before a superintendent or officer of customs, and at any port abroad where there is a British consular officer, before such officer. Before a seaman can be discharged at any place abroad, the master must obtain the sanction, endorsed on the agreement with the crew, of the like officials or, in their absence, of merchants there resident. When a seaman is discharged in a foreign country, he is entitled to be provided with adequate employment on some other British ship bound to the port in His Majesty's dominions at which he was originally shipped, or to a port in the United Kingdom agreed to by the seaman, or to be furnished with the means of returning to such port or of a passage home. It is a misdemeanour wrongfully to force a seaman on shore, or otherwise wrongfully leave him behind in any place before the completion of the voyage for which he was engaged, or the return of the ship to the United Kingdom. The only persons by whom seamen may be engaged or supplied in the United Kingdom are a superintendent, the master, the mate, a servant *bonâ fide* in the constant employ of the owner, and any person holding a licence from the Board of Trade.

The law as to seamen's wages has not been altered. Where a seaman is discharged before a superintendent in the United

Kingdom, his wages must be paid through or in the presence of the superintendent, and in the case of home-trade ships may be so paid if the master or owner so desire. The master must in every case deliver either to the superintendent or to the seaman a full account, in a form approved by the Board of Trade, of the wages and of all deductions therefrom; such deductions will only be allowed if they have been entered by the master during the voyage in a book kept for that purpose, together with a statement of the matters in respect of which they are made. Where a seaman is left abroad on the ground of his unfitness or inability to proceed on the voyage, the account of wages must be delivered to the superintendent, chief officer of customs, consular officer, or merchants, from whom the master obtains the certificate without which he may not leave the seaman behind. In order to protect seamen from crimps, advance notes, or documents authorizing or promising the future payment of money on account of a seaman's wages conditionally on his going to sea from any port of the United Kingdom, and made before those wages had been earned, were from 1880 to 1889 wholly void, and no money paid in satisfaction or in respect of any such document could be deducted from a seaman's wages. Since 1889 this restriction has been removed to the extent of one month's wages, provided that the agreement with the crew contains a stipulation for such advance. It is to be observed that this does not extend to cases where the seaman is going to sea from any port not in the United Kingdom. In such cases there is no limitation upon the right to make any agreement for advances or to make advances to any amount. It has been held that the old statute, 8 Geo. I. c. 24, § 7, does not forbid an advance to a seaman engaged abroad, or if it does, does not enable a seaman to recover the sum advanced again as unpaid wages.

As under the former law, the scale of provisions must be entered in the agreement with the crew, and compensation made for short or bad provisions, and means are provided whereby the crew can raise complaints. But, in addition, in the case of ships trading or going from any port in the United Kingdom through the Suez Canal or round the Cape of Good Hope or Cape Horn, the provisions and water are put under inspection by the Board of Trade, and if they are deficient, the ship may be detained until the defects are remedied.

The law as to the property of deceased seamen, the reimbursement of relief to seamen's families, the relief of destitute and distressed seamen, discipline, and volunteering into the navy, remains substantially unaltered. The law as to medicines, anti-scorbutics, and medical inspection, and as to crew space, continues the same. If a seaman receives hurt or injury in the service of the ship, the expense of medical attendance and maintenance, together with the cost of bringing him home, is to be borne by the owner of the ship, and cannot be deducted from wages.

The safety of the crew is secured by provisions which are designed to prevent overloading and undermanning, to restrict the carriage of dangerous cargoes, to secure adequate life-saving appliances, and generally to prevent ships from being sent to sea in an unseaworthy state. The stringency of these provisions has been much increased. Life-saving appliances, including boats, life-belts, and the like, according to a scale and rules prescribed by the Board of Trade, must be carried by every British ship. Except where the ship is under 80 tons register, employed solely in the coasting trade, or is employed solely in fishing, or is a pleasure yacht, the position of each deck above water must be marked by conspicuous lines, and the maximum load line in salt water, to which it shall be lawful to load the ship, must be marked at such level as may be approved by the Board of Trade below the deck line, and in accordance with tables and regulations prescribed by the Board of Trade. It is this load line which is commonly known as the Plimsoll mark. It is an offence to load a ship so as to submerge the load line, and a ship so loaded may be detained as unsafe. Dangerous goods, *e.g.*, explosives, must not be shipped or carried without being distinctly marked as such. Timber must not be carried on deck in the winter months. In the carriage of grain cargoes, rules prescribed by the Board of Trade to prevent shifting must be complied with. The officers of the Board of Trade (subject to appeal to a Court of Survey from an order of final detention) have power to detain any unsafe ship, that is a ship which is, by reason of the defective condition of the hull, equipments, or machinery, or of undermanning, overloading or improper loading, unfit to proceed to sea without serious danger to human life, having regard to the service for which she is intended. Provision is made for the investigation of complaints by seamen that a ship is unfit to proceed to sea.

The manning of British merchant ships has received much consideration, but has hitherto been little affected by statute law. The effect of the Acts is thus given in the report, issued in 1896, by a Board of Trade Committee on the Manning of Merchant Ships:—"Since the final repeal of the Navigation Laws, which required that the master and three-fourths of the crew of every British ship should be British subjects, and reserved the coasting trade entirely to British ships and British seamen, the whole world has been open as a recruiting ground to British shipowners, who have not been hampered in their selection by any restriction as to colour, language, qualification, age, or strength. Except with regard to certificates, which must be held by masters, officers, and engineers in certain cases, and which, moreover, may be obtained by men of any nationality, there is at present practically no bar to the employment of any person of any nationality in any capacity whatsoever on board any British ship."

Certificates of competency as masters, mates, and engineers are granted by the Board of Trade. Such certificates are for the following grades, viz., master or first mate, or second mate, or only mate of a foreign-going ship, master or mate of a home-trade passenger ship, first or second class engineer. By virtue of Orders in Council under section 102 of the Act of 1894, certificates granted in many of the British colonies have the same force as if granted by the Board of Trade. The following are the requirements of the Act as to the officers to be carried by ships:—*Masters*: A properly certificated master must be carried by every foreign-going ship and every home-trade passenger ship, whatever their tonnage. *Mates*: A mate, with the certificate of the grade of first or only mate, or master, must, in addition to the certificated master, be carried by every foreign-going ship of 100 tons or upwards, unless more than one mate is carried, in which case the first and second mates must have valid certificates appropriate to their several stations on such ship or of a higher grade; and a mate, with a certificate of the grade of first or only mate or master, must, in addition to the certificated master, be carried by every home-trade passenger ship of 100 tons or upwards. *Engineers*: Every foreign-going steamship of 100 nominal horse power or upwards must have two certificated engineers—the first possessing a first-class engineer's certificate, and the second possessing a second-class engineer's certificate, or a certificate of the higher grade. Every other foreign-going steamship, and every sea-going home-trade passenger steamship, is required to carry as the first or only engineer an engineer having a second-class certificate, or a certificate of the higher grade. Vessels in the home trade (*i.e.*, United Kingdom and continent of Europe between the Elbe and Brest) are not required to carry certificated masters or officers unless they are passenger ships of 100 tons or upwards; and vessels in the foreign trade of less than 100 tons are not required to carry any mate.

The Merchant Shipping Act, 1897, gives power to the Board of Trade to detain ships unseaworthy by reason of undermanning, but prescribes no rules for determining when a ship is to be deemed to be undermanned. And apart from that Act, the law does not interfere with the number or qualifications of the crew. The law does not prescribe that the crew or any portion of it should be British, or that it should consist, in any proportion, of able-bodied seamen. In 1898 a slight attempt was made to encourage shipowners to carry apprentices to the sea service. The Merchant Shipping Act of that year, which dealt with light dues, provided that "on proof to the satisfaction of the Board of Trade that a British ship has during any financial year carried, in accordance with the scale and regulations to be made by the Board of Trade, with the concurrence of the Treasury, boys between the ages of 15 and 19, there shall be paid to the owner of the ship, out of moneys to be provided by Parliament, an allowance not exceeding one-fifth of the light dues paid during that year in respect of that ship. Provided that no such payment shall be made in respect of anybody

unless he has enrolled himself in the Royal Naval Reserve, and entered into an obligation to present himself for service when called upon in accordance with rules to be issued by the Admiralty." This enactment is to continue until 1905; it has been so little acted upon that some more efficient means will have to be devised, if apprenticeship to the sea service is to be revived; at present it has practically ceased to exist, except in the case of boys who intend to become officers.

Some only of the provisions of the Acts apply to ships belonging to the general lighthouse authorities and pleasure yachts. But, with these exceptions, the whole of Part II. (Masters and Seamen) applies, unless the contract or subject-matter requires a different application, to all sea-going ships registered in the United Kingdom. Where a ship is a British ship, but not registered in the United Kingdom, the provisions of Part II. apply as follows:—The provisions relating to the shipping and discharge of seamen in the United Kingdom and to volunteering into the navy apply in every case. The provisions relating to lists of the crew and to the property of deceased seamen and apprentices apply where the crew are discharged or the final port of destination of the ship is in the United Kingdom. All the provisions apply where the ship is employed in trading or going between any port in the United Kingdom, and any port not situate in the British possession or country in which the ship is registered. The provisions relating to the rights of seamen in respect of wages, to the shipping and discharge of seamen in ports abroad, to leaving seamen abroad, and the relief of seamen in distress in ports abroad, to the provisions, health, and accommodation of seamen, to the power of seamen to make complaints, to the protection of seamen from imposition, and to discipline, apply in every case except where the ship is within the jurisdiction of the government of the British possession in which the ship is registered.

The law as to the registration of fishing boats, and generally as to men employed in fishing, is now to be found in the Merchant Shipping Act, 1894, and especially in Part IV. of that Act. The Act does not apply to fishing boats in British possessions, and, speaking generally, fishing boats in Scotland are governed by Part II. (Master and Seamen) and not by Part IV. By a recent change in the law, a trawler of 25 tons and upwards must carry a certificated second hand as well as a certificated skipper.

In most British colonies there are laws affecting merchant seamen. In some cases such legislation is identical with the Imperial Act, but in most there are differences of more or less importance, and the colonial statutes should be consulted. Reference may be made to the following Indian and Colonial Acts and ordinances:—*Bahamas:* 2 Vict. c. 3; 21 Vict. c. 2; 27 Vict. c. 2; 28 Vict. c. 1; 28 Vict. c. 28; 33 Vict. c. 15; 36 Vict. c. 1; 43 Vict. c. 20. *Barbados:* No. 45 of 1891; No. 12 of 1898. *Bermuda:* No. 17 of 1782; No. 22 of 1848; No. 6 of 1849; No. 14 of 1867; No. 13 of 1873; No. 7 of 1876; No. 4 of 1878; No. 10 of 1878; Nos. 2 and 5 of 1880; No. 5 of 1884; Nos. 16, 25, and 31 of 1900. *British Guiana:* No. 6 of 1864; No. 4 of 1883; No. 2 of 1895; No. 10 of 1900. *Canada:* Revised statutes, chapters 73, 74, 76 and 77; Nos. 21 and 22 of 1889; Nos. 38, 40 and 41 of 1891; No. 22 of 1893; Nos. 42, 43, 44 and 45 of 1894; Nos. 45 and 46 of 1898; No. 34 of 1901. *Cape of Good Hope:* No. 13 of 1855; No. 3 of 1863; No. 2 of 1870; No. 13 of 1874. *Ceylon:* No. 7 of 1863; No. 3 of 1880; No. 3 of 1884; No. 3 of 1888; No. 6 of 1899. *Honduras:* Consolidated Laws, chapters 54 and 55. *Hong Kong:* No. 36 of 1899. *India:* No. 1 of 1859; No. 13 of 1873; No. 13 of 1876; No. 7 of 1880; No. 5 of 1883; No. 7 of 1884; Nos. 6, 12, and 17 of 1891; No. 15 of 1894. *Jamaica:* 2 Will. IV. c. 32; 6 Will. Sea-Power.—A term used to indicate two distinct, though cognate, things. The affinity of these two and the indiscriminate manner in which the term has been applied to each have tended to obscure its real significance. The obscurity has been deepened by the frequency with which the term has been confounded with the old phrase, "Sovereignty of the sea," and the still current expression, "Command of the sea" (*vide* SEA, COMMAND OF). A discussion—etymological, or even archæological in character—of the term must be undertaken as an introduction to the explanation of its now generally accepted meaning. It is one of those compound words in which a Teutonic and a Latin (or Romance) element are combined, and which are easily formed and become widely current when the sea is concerned. Of such are "sea-coast," "sea-forces" (the "land- and sea-forces" used to be a common designation of what we now call the "Army and Navy"); "sea-service," "sea-serpent," and "sea-officer" (now superseded by "naval officer"). The term in one form is as old as the 15th century. Edward III., in commemoration of the naval victory of Sluys, coined gold "nobles" which bore on one side his effigy "crowned, standing in a large ship, holding in one hand a sword and in the other a shield." An anonymous poet, who wrote in the reign of Henry VI., says of this coin:—

History of the term.

> For four things our noble showeth to me,
> King, ship and sword, and *power of the sea.*

Even in its present form the term is not of very recent date. Grote (*Hist. of Greece*, v. p. 67, published in 1849, but with preface dated 1848) speaks of "the conversion of Athens from a land-power into a sea-power." In a lecture published in 1883, but probably delivered earlier, the late Sir J. R. Seeley says that "commerce was swept out of the Mediterranean by the besom of the Turkish sea-power" (*Expansion of England*, p. 89). The term also occurs in vol. xviii. of this Encyclopædia, published in 1885. At p. 574 of that volume (PERSIA) we are

told that Themistocles was "the founder of the Attic sea-power." The sense in which the term is used differs in these extracts. In the first it means what we generally call a "naval power"—that is to say, a State having a considerable navy in contradistinction to a "military power," a State with a considerable army but only a relatively small navy. In the last two extracts it means all the elements of the naval strength of the State referred to; and this is the meaning that is now generally, and is likely to be exclusively, attached to the term owing to the brilliant way in which it has been elucidated by Captain A. T. Mahan of the United States Navy in a series of remarkable works (*Influence of Sea-power on History*, published 1890; *Influence of Sea-power on the French Revolution and Empire*, 2 vols. 1892; *Nelson: the Embodiment of the Sea-power of Great Britain*, 2 vols. 1897). The double use of the term is common in German, though in that language both parts of the compound now in use are Teutonic. One instance out of many may be cited from the historian Adolf Holm (*Griechische Geschichte*, Berlin, 1889). He says (ii. p. 37) that Athens, being in possession of a good naval port, could become "*eine bedeutende Seemacht*," *i.e.*, an important naval power. He also says (ii. p. 91) that Gelon of Syracuse, besides a large army (*Heer*), had "*eine bedeutende Seemacht*," meaning a considerable navy. The term, in the first of the two senses, is old in German, as appears from the following, extracted from Zedler's *Grosses Universal Lexicon*, vol. xxxvi. (Leipzig and Halle, 1743): "Seemachten, Seepotenzen; Latin, *summae potestates mari potentes*." "Seepotenzen" is probably quite obsolete now. It is interesting as showing that German no more abhors Teuto-Latin or Teuto-Romance compounds than English. We may note, as a proof of the indeterminate meaning of the expression until his own epoch-marking works had appeared, that Mahan himself in his earliest book used it in both senses. He says (p. 35), "The Spanish Netherlands ceased to be a sea-power." He alludes (p. 42) to the development of a nation as a "sea-power," and (p. 43) to the inferiority of the Confederate States "as a sea-power." Also (p. 225) he remarks of the war of the Spanish Succession that "before it England was one of the sea-powers, after it she was *the* sea-power without any second." In all these passages, as appears from the use of the indefinite article, what is meant is a naval power, or a State in possession of a strong navy. The other meaning of the term forms the general subject of his writings above enumerated. In his earlier works Mahan writes "sea power" as two words; but in a published letter of the 19th February 1897, he joins them with a hyphen, and defends this formation of the term and the sense in which he uses it. We may regard him as the virtual inventor of the term in its more diffused meaning, for—even if it had been employed by earlier writers in that sense—it is he beyond all question who has given it general currency. He has made it impossible for any one to treat of sea-power without frequent reference to his writings and conclusions.

Appreciation of sea-power by the ancients.

There is something more than mere literary interest in the fact that the term in another language was used more than two thousand years ago. Before Mahan no historian—not even one of those who specially devoted themselves to the narration of naval occurrences—had evinced a more correct appreciation of the general principles of naval warfare than Thucydides. He alludes several times to the importance of getting command of the sea. Great Britain would have been saved some disasters and been less often in peril had British writers—taken as guides by the public—possessed the same grasp of the true principles of defence as Thucydides exhibited. One passage in his history is worth quoting. Brief as it is, it shows that on the subject of sea-power he was a predecessor of Mahan. In a speech in favour of prosecuting the war, which he puts in the mouth of Pericles, these words occur:—*οἱ μὲν γὰρ οὐχ ἕξουσιν ἄλλην ἀντιλαβεῖν ἀμαχεί, ἡμῖν δέ ἐστι γῆ πολλὴ καὶ ἐν νήσοις καὶ κατ᾽ ἤπειρον· μέγα γὰρ τὸ τῆς θαλάσσης κράτος.* The last part of this extract, though often translated "command of the sea," or "dominion of the sea," really has the wider meaning of sea-power, the "power of the sea" of the old English poet above quoted. This wider meaning should be attached to certain passages in Herodotus (iii. 122 in two places; v. 83), which have been generally interpreted "commanding the sea," or by the mere titular and honorific "having the dominion of the sea." One editor of Herodotus, Ch. F. Baehr, did, however, see exactly what was meant, for, with reference to the allusion to Polycrates, he says, *classe maximum valuit.* This is perhaps as exact a definition of sea-power as could be given in a sentence.

Can only be explained historically.

It is, however, impossible to give a definition which would be at the same time succinct and satisfactory. To say that "sea-power" means the sum total of the various elements that go to make up the naval strength of a State would be in reality to beg the question. Mahan lays down the "principal conditions affecting the sea-power of nations," but he does not attempt to give a concise definition of it. Yet no one who has studied his works will find it difficult to understand what it indicates. Our present task is, within the necessarily restricted limits of an article in an encyclopædia, to put readers in possession of the means of doing this. The best, indeed—as Mahan has shown us—the only effective way of attaining this object is to treat the matter historically. Whatever date we may agree to assign to the formation of the term itself, the idea—as we have seen—is as old as history. It is not intended to give a condensed history of sea-power, but rather an analysis of the idea and what it contains, illustrating this analysis with examples from history ancient and modern. It is important to know that it is not something which originated in the middle of the 17th century, and having seriously affected history in the 18th, ceased to have weight till Captain Mahan appeared to comment on it in the last decade of the 19th. With a few masterly touches Mahan, in his brief allusion to the second Punic war, has illustrated its importance in the struggle between Rome and Carthage. What has to be shown is that the principles which he has laid down in that case, and in cases much more modern, are true and have been true always and everywhere. Until this is perceived there is much history which cannot be understood, and yet it is essential to the welfare of Great Britain as a maritime power that she should understand it thoroughly. Her failure to understand it has more than once brought her, if not to the verge of destruction, at any rate within a short distance of serious disaster.

The high antiquity of decisive naval campaigns is among the most interesting features of international conflicts. Notwithstanding the much greater frequency of land wars, the course of history has been profoundly changed more often by contests on the water. That this has not received the notice it deserved is true, and Mahan tells us why. "Historians generally," he says, "have been unfamiliar with the conditions of the sea, having as to it neither special interest nor special knowledge; and the profound determining influence of maritime strength on great issues has consequently been overlooked." Moralizing on that which might have been is admittedly a sterile process; but it is sometimes necessary to point, if

only by way of illustration, to a possible alternative. As in modern times the fate of India and the fate of North America were determined by sea-power, so also at a very remote epoch sea-power decided whether or not Hellenic colonization was to take root in, and Hellenic culture to dominate, central and northern Italy as it dominated southern Italy, where traces of it are extant to this day.

Early manifestations of sea-power.

A moment's consideration will enable us to see how different the history of the world would have been had a Hellenized city grown and prospered on the Seven Hills. Before the Tarquins were driven out of Rome a Phocæan fleet was encountered (537 B.C.) off Corsica by a combined force of Etruscans and Phœnicians, and was so handled that the Phocæans abandoned the island and settled on the coast of Lucania (Mommsen, *Hist. Rome*, English trans. i. p. 153). The enterprise of their navigators had built up for the Phœnician cities and their great off-shoot Carthage, a sea-power which enabled them to gain the practical sovereignty of the sea to the west of Sardinia and Sicily. The control of these waters was the object of prolonged and memorable struggles, for on it—as the result showed—depended the empire of the world. From very remote times the consolidation and expansion, from within outwards, of great continental States have had serious consequences for mankind when they were accompanied by the acquisition of a coast-line and the absorption of a maritime population. We shall find that the process loses none of its importance in recent years. "The ancient empires," says the historian of Greece, Ernst Curtius, "as long as no foreign elements had intruded into them, had an invincible horror of the water." When the condition, which Curtius notices in parenthesis, arose the "horror" disappeared. There is something highly significant in the uniformity of the efforts of Assyria, Egypt, Babylon, and Persia to get possession of the maritime resources of Phœnicia. Our own immediate posterity will perhaps have to reckon with the results of similar efforts in our own day. It is this which gives a living interest to even the very ancient history of sea-power, and makes the study of it of great practical importance to us now. We shall see, as we go on, how the phenomena connected with it reappear with striking regularity in successive periods. Looked at in this light the great conflicts of former ages are full of useful, indeed necessary, instruction.

Wars of the Greeks and Persians.

In the first and greatest of the contests waged by the nations of the East against Europe—the Persian wars—sea-power was the governing factor. Until Persia had expanded to the shores of the Levant the European Greeks had little to fear from the ambition of the great king. The conquest of Egypt by Cambyses had shown how formidable that ambition could be when supported by an efficient navy. With the aid of the naval forces of the Phœnician cities the Persian invasion of Greece was rendered comparatively easy. It was the naval contingents from Phœnicia which crushed the Ionian revolt. The expedition of Mardonius, and still more that of Datis and Artaphernes, had indicated the danger threatening Greece when the master of a great army was likewise the master of a great navy. Their defeat at Marathon was not likely to, and as a matter of fact did not, discourage the Persians from further attempts at aggression. As the advance of Cambyses into Egypt had been flanked by a fleet, so also was that of Xerxes into Greece. By the good fortune sometimes vouchsafed to a people, which, owing to its obstinate opposition to, or neglect of a wise policy, scarcely deserves it, there appeared at Athens an influential citizen who understood all that was meant by the term sea-power. Themistocles saw more clearly than any of his contemporaries that, to enable Athens to play a leading part in the Hellenic world, she needed above all things a strong navy. "He had already in his eye the battle-field of the future." He felt sure that the Persians would come back, and come with such forces that resistance in the open field would be out of the question. One scene of action remained—the sea. Persuaded by him the Athenians increased their navy, so that of the 271 vessels comprising the Greek fleet at Artemisium, 147 had been provided by Athens, which also sent a large reinforcement after the first action. Though no one has ever surpassed Themistocles in the faculty of correctly estimating the importance of sea-power, it was understood by Xerxes as clearly as by him that the issue of the war depended upon naval operations. The arrangements made under the Persian monarch's direction, and his very personal movements, show that this was his view. He felt, and probably expressed the feeling, exactly as—in the war of American Independence—Washington did in the words, "Whatever efforts are made by the land armies, the navy must have the casting vote in the present contest." The decisive event was the naval action of Salamis. To have made certain of success, the Persians should have first obtained a command of the Aegean, as complete for all practical purposes as the French and English had of the sea generally in the war against Russia of 1854–56. The Persian sea-power was not equal to the task. The fleet of the great king was numerically stronger than that of the Greek allies; but it has been proved many times that naval efficiency does not depend on numerical superiority alone. The choice sections of the Persian fleet were the contingents of the Ionians and Phœnicians. The former were half-hearted or disaffected; while the latter were, at best, not superior in skill, experience, and valour to the Greek sailors. At Salamis Greece was saved not only from the ambition and vengeance of Xerxes, but also and for many centuries from oppression by an Oriental conqueror. Persia did not succeed against the Greeks, not because she had no sea-power, but because her sea-power, artificially built up, was inferior to that which was a natural element of the vitality of her foes. Ionia was lost and Greece in the end enslaved, because the quarrels of Greeks with Greeks led to the ruin of their naval States.

Peloponnesian War.

The Peloponnesian was largely a naval war. The confidence of the Athenians in their sea-power had a great deal to do with its outbreak. The immediate occasion of the hostilities, which in time involved so many States, was the opportunity offered by the conflict between Corinth and Corcyra of increasing the sea-power of Athens. Hitherto the Athenian naval predominance had been virtually confined to the Aegean Sea. The Corcyræan envoy, who pleaded for help at Athens, dwelt upon the advantage to be derived by the Athenians from alliance with a naval State occupying an important situation "with respect to the western regions towards which the views of the Athenians had for some time been directed" (Thirlwall, *Hist. Greece*, iii. p. 96). It was the "weapon of her sea-power," to adopt Mahan's phrase, that enabled Athens to maintain the great conflict in which she was engaged. Repeated invasions of her territory, the ravages of disease among her people, and the rising disaffection of her allies had been more than made up for by her predominance on the water. The scale of the subsequent Syracusan expedition showed how vigorous Athens still was down to the interruption of the war by the peace of Nicias. The great expedition just mentioned overtaxed her strength. Its failure brought about the ruin of the State. It was

held by contemporaries, and has been held in our own day, that the Athenian defeat at Syracuse was due to the omission of the government at home to keep the force in Sicily properly supplied and reinforced. This explanation of failure is given in all ages, and should always be suspected. The friends of unsuccessful generals and admirals always offer it, being sure of the support of the political opponents of the administration. After the despatch of the supporting expedition under Demosthenes and Eurymedon no further great reinforcement, as Nicias admitted, was possible. The weakness of Athens was in the character of the men who swayed the popular assemblies and held high commands. A people which remembered the administration of a Pericles, and yet allowed a Cleon or an Alcibiades to direct its naval and military policy, courted defeat. Nicias, notwithstanding the possession of high qualities, lacked the supreme virtue of a commander—firm resolution. He dared not face the obloquy consequent on withdrawal from an enterprise on which the popular hopes had been fixed; and therefore he allowed a reverse to be converted into an overwhelming disaster. "The complete ruin of Athens had appeared, both to her enemies and to herself, impending and irreparable. But so astonishing, so rapid, and so energetic had been her rally, that [a year after Syracuse] she was found again carrying on a terrible struggle" (Grote, *Hist. Greece*, v. p. 354). Nevertheless her sea-power had indeed been ruined at Syracuse. Now she could wage war only "with impaired resources and on a purely defensive system." Even before Arginusæ it was seen that "superiority of nautical skill had passed to the Peloponnesians and their allies" (*ibid.* p. 503).

Struggle between Rome and Carthage.

The great, occasionally interrupted, and prolonged contest between Rome and Carthage was a sustained effort on the part of one to gain and of the other to keep the control of the western Mediterranean. So completely had that control been exercised by Carthage, that she had anticipated the Spanish commercial policy in America. The Romans were precluded by treaties from trading with the Carthaginian territories in Hispania, Africa, and Sardinia. Rome, as Mommsen tells us, "was from the first a maritime city and, in the period of its vigour, never was so foolish or so untrue to its ancient traditions as wholly to neglect its war marine and to desire to be a mere continental power." It may be that it was lust of wealth rather than lust of dominion that first prompted a trial of strength with Carthage. The vision of universal empire could hardly as yet have formed itself in the imagination of a single Roman. The area of Phœnician maritime commerce was vast enough both to excite jealousy and to offer vulnerable points to the cupidity of rivals. It is probable that the modern estimate of the sea-power of Carthage is much exaggerated. It was great by comparison, and of course overwhelmingly great when there were none but insignificant competitors to challenge it. Mommsen holds that, in the fourth and fifth centuries after the foundation of Rome, "the two main competitors for the dominion of the Western waters" were Carthage and Syracuse. "Carthage," he says, "had the preponderance, and Syracuse sank more and more into a second-rate naval power. The maritime importance of the Etruscans was wholly gone. . . . Rome itself was not exempt from the same fate; its own waters were likewise commanded by foreign fleets." The Romans were for a long time too much occupied at home to take much interest in Mediterranean matters. The position of the Carthaginians in the western basin of the Mediterranean was very like that of the Portuguese long afterwards in India. The latter kept within reach of the sea; "nor did their rule ever extend a day's march from their ships" (R. S. Whiteway, *Rise of the Portuguese Power in India.* Westminster, 1899, p. 12). "The Carthaginians in Spain," says Mommsen, "made no effort to acquire the interior from the warlike native nations; they were content with the possession of the mines and of stations for traffic and for shell and other fisheries." Allowance being made for the numbers of the classes engaged in administration, commerce, and supervision, it is nearly certain that Carthage could not furnish the crews required by both a great war-navy and a great mercantile marine. No one is surprised on finding that the land-forces of Carthage were composed largely of alien mercenaries. We have several examples from which we can infer a parallel, if not an identical, condition of her maritime resources. How, then, was the great Carthaginian carrying-trade provided for? The experience of more than one country will enable us to answer this question. The ocean trade of those off-shoots or dependencies of the United Kingdom, viz., the United States, Australasia, and India, is largely or chiefly conducted by shipping of the "old country." So that of Carthage was largely conducted by old Phœnicians. These may have obtained a "Carthaginian Register," or the contemporary equivalent; but they could not all have been purely Carthaginian or Liby-Phœnician. This must have been the case even more with the war-navy. British India for a considerable time possessed a real, and indeed highly efficient navy; but it was officered entirely and manned almost entirely by men from the old country. Moreover, it was small. The wealth of India would have sufficed to furnish a larger material element; but, as the country could not supply the *personnel*, it would have been absurd to speak of the sea-power of India apart from that of England. As soon as the Romans chose to make the most of their natural resources the maritime predominance of Carthage was doomed. The artificial basis of the latter's sea-power would not enable it to hold out against serious and persistent assaults. Unless this is perceived, it is impossible to understand the story of the Punic wars. Judged by every visible sign of strength, Carthage, the richer, the more enterprising, ethnically the more predominant among her neighbours, and apparently the more nautical, seemed sure to win in the great struggle with Rome which, by the conditions of the case, was to be waged largely on the water. Yet those who had watched the struggles of the Punic city with the Sicilian Greeks, and especially that with Agathocles, must have seen reason to cherish doubts concerning her naval strength. It was an anticipation of the case of Spain in the age of Philip II. As the great Elizabethan seamen discerned the defects of the Spanish naval establishment, so men at Rome discerned those of the Carthaginian. Dates in connexion with this are of great significance. A comprehensive measure, with the object of "rescuing their marine from its condition of impotence" was taken by the Romans in the year 267 B.C. Four *quæstores classici*—in modern naval English we may perhaps call them port-admirals—were nominated, and one was stationed at each of four ports. The objects of the Roman Senate, so Mommsen tells us, were very obvious. They were "to recover their independence by sea, to cut off the maritime communications of Tarentum, to close the Adriatic against fleets coming from Epirus, and to emancipate themselves from Carthaginian supremacy." Four years afterwards the first Punic war began. It was, and had to be, largely a naval contest. The Romans waged it with varying fortune, but in the end triumphed by means of their sea-power. The victory of Catulus over the Carthaginian fleet off the Aegadian Islands decided the war and left to the Romans the possession of Sicily and the power of possessing them-

selves of Sardinia and Corsica. It would be an interesting and perhaps not barren investigation to inquire to what extent the decline of the mother states of Phœnicia, consequent on the campaigns of Alexander the Great, had helped to enfeeble the naval efficiency of the Carthaginian defences. One thing was certain. Carthage had now met with a rival endowed with natural maritime resources greater than her own. That rival also contained citizens who understood the true importance of sea-power. "With a statesmanlike sagacity from which succeeding generations might have drawn a lesson, the leading men of the Roman Commonwealth perceived that all their coast-fortifications and coast-garrisons would prove inadequate unless the war-marine of the State were again placed on a footing that should command respect" (Mommsen, i. 427). It is a gloomy reflection that the leading men of the United Kingdom could not see this in 1860. A thorough comprehension of the events of the first Punic war enables us to solve what, until Mahan wrote, had been one of the standing enigmas of history, viz., Hannibal's invasion of Italy by land instead of by sea in the second Punic war. Mahan's masterly examination of this question has set at rest all doubts as to the reason of Hannibal's action (*Influence on Hist.* pp. 13–21). The naval predominance in the western basin of the Mediterranean acquired by Rome had never been lost. Though modern historians, even those belonging to a maritime country, may have failed to perceive it, the Carthaginians knew well enough that the Romans were too strong for them on the sea. Though other forces co-operated to bring about the defeat of Carthage in the second Punic war, the Roman navy, as Mahan demonstrates, was the most important. As a navy, he tells us in words like those already quoted, "acts on an element strange to most writers, as its members have been from time immemorial a strange race apart, without prophets of their own, neither themselves nor their calling understood, its immense determining influence on the history of that era, and consequently upon the history of the world, has been overlooked."

Expansion of Roman dominion furthered by sea-power.

The attainment of all but universal dominion by Rome was now only a question of time. "The annihilation of the Carthaginian fleet had made the Romans masters of the sea" (Schmitz, *Hist. Rome*, p. 256). A lodgment had already been gained in Illyricum, and countries farther east were before long to be reduced to submission. A glance at the map will show that to effect this the command of the eastern basin of the Mediterranean, like that of the western, must be secured by the Romans. The old historic navies of the Greek and Phœnician States had declined. One considerable naval force there was which, though it could not have prevented, was strong enough to have delayed the Roman progress eastwards. This force belonged to Rhodes, which in the years immediately following the close of the second Punic war reached its highest point as a naval power (C. Torr, *Rhodes in Ancient Times*, p. 40). Far from trying to obstruct the advance of the Romans the Rhodian fleet helped it. Hannibal, in his exile, saw the necessity of being strong on the sea if the East was to be saved from the grasp of his hereditary foe; but the resources of Antiochus, even with the mighty co-operation of Hannibal, were insufficient. In a later and more often quoted struggle between East and West—that which was decided at Actium—sea-power was again seen to "have the casting vote." When the whole of the Mediterranean coasts became part of a single State the importance of the navy was naturally diminished; but in the struggles within the declining empire it rose again at times. The contest of the Vandal Genseric with Majorian and the African expedition of Belisarius—not to mention others—were largely influenced by the naval operations (Gibbon, *Decline and Fall*, chaps. xxxvi. xli.).

Extension westward of Mahommedan conquest.

A decisive event, the Mahommedan conquest of northern Africa from Egypt westwards, is unintelligible until it is seen how great a part sea-power played in effecting it. Purely land expeditions, or expeditions but slightly supported from the sea, had ended in failure. The emperor at Constantinople still had at his disposal a fleet capable of keeping open the communications with his African province. It took the Saracens half a century (A.D. 647–698) to win "their way along the coast of Africa as far as the Pillars of Hercules" (Hallam, *Mid. Ages*, chap. vi.); and, as Gibbon tells us, it was not till the Commander of the Faithful had prepared a great expedition, this time by sea as well as by land, that the Saracenic dominion was definitely established. It has been generally assumed that the Arabian conquerors who, within a few years of his death, spread the faith of Mahommed over vast regions, belonged to an essentially non-maritime race; and little or no stress has been laid on the extent to which they relied on naval support in prosecuting their conquests. In parts of Arabia, however, maritime enterprise was far from non-existent; and when the Mahommedan empire had extended outwards from Mecca and Medina till it embraced the coasts of various seas, the consequences to the neighbouring states were as serious as the rule above mentioned would lead us to expect that they would be. "With the conquest of Syria and Egypt a long stretch of sea-board had come into the Saracenic power; and the creation and maintenance of a navy for the protection of the maritime ports as well as for meeting the enemy became a matter of vital importance. Great attention was paid to the manning and equipment of the fleet" (Amir Ali, Syed, *Short Hist. Saracens*, p. 442). At first the fleet was manned by sailors drawn from the Phœnician towns, where nautical energy was not yet quite extinct; and later the crews were recruited from Syria, Egypt, and the coasts of Asia Minor. Ships were built at most of the Syrian and Egyptian ports, and "also at Obolla and Bushire on the Persian Gulf," whilst the mercantile marine and maritime trade were fostered and encouraged. The sea-power thus created was largely artificial. It drooped—as in similar cases—when the special encouragement was withdrawn. "In the days of Arabian energy," says Hallam, "Constantinople was twice, in 668 and 716, attacked by great naval armaments." The same authority believes that the abandonment of such maritime enterprises by the Saracens may be attributed to the removal of the capital from Damascus to Bagdad. The removal indicated a lessened interest in the affairs of the Mediterranean Sea, which was now left by the administration far behind. "The Greeks in their turn determined to dispute the command of the sea," with the result that in the middle of the 10th century their empire was far more secure from its enemies than under the first successors of Heraclius." Not only was the fall of the empire, by a rational reliance on sea-power, postponed for centuries, but also much that had been lost was regained. "At the close of the 10th century the emperors of Constantinople possessed the best and greatest part" of southern Italy, part of Sicily, the whole of what is now called the Balkan Peninsula, Asia Minor, with some parts of Syria and Armenia (Hallam, chap. vi.; Gibbon, chap. li.).

Neglect of sea-power by those who can be reached by sea brings its own punishment. Whether neglected or not, if it is an artificial creation it is nearly sure to disappoint those who wield it when it encounters a rival power of natural growth. How was it possible for the Crusaders, in their various expeditions, to achieve even

the transient success that occasionally crowned their efforts? How did the Christian kingdom of Jerusalem contrive to exist for more than three-quarters of a century? Why did the Crusades more and more become maritime expeditions? The answer to these questions is to be found in the decline of the Mahommedan naval defences and the rising enterprise of the seafaring people of the West. Venetians, Pisans, and Genoese transported crusading forces, kept open the communications of the places held by the Christians, and hampered the operations of the infidels. Even the great Saladin failed to discern the important alteration of conditions. This is evident when we look at the efforts of the Christians to regain the lost kingdom. Saladin "forgot that the safety of Phœnicia lay in immunity from naval incursions, and that no victory on land could ensure him against an influx from beyond the sea" (Amir Ali, Syed, pp. 359–360). Not only were the Crusaders helped by the fleets of the maritime republics of Italy, they also received reinforcements by sea from western Europe and England, on the "arrival of *Malik Ankiltar* [Richard Cœur de Lion] with twenty shiploads of fighting men and munitions of war."

Sea-power and the Crusades.

Participation in the Crusades was not a solitary proof of the importance of the naval states of Italy. That they had been able to act effectively in the Levant may have been in some measure due to the weakening of the Mahommedans by the disintegration of the Seljukian power, the movements of the Moguls, and the confusion consequent on the rise of the Ottomans. However that may have been, the naval strength of those Italian states was great absolutely as well as relatively. Sismondi, speaking of Venice, Pisa, and Genoa, towards the end of the 11th century, says "these three cities had more vessels on the Mediterranean than the whole of Christendom besides" (*Ital. Republics*, English ed., p. 29). Dealing with a period two centuries later, he declares it "difficult to comprehend how two simple cities could put to sea such prodigious fleets as those of Pisa and Genoa." The difficulty disappears when we have Mahan's explanation. The maritime republics of Italy—like Athens and Rhodes in ancient, Catalonia in mediæval, and England and the Netherlands in more modern times—were "peculiarly well fitted, by situation and resources, for the control of the sea by both war and commerce." As far as the western Mediterranean was concerned, Genoa and Pisa had given early proofs of their maritime energy, and fixed themselves, in succession to the Saracens, in the Balearic Isles, Sardinia, and Corsica. Sea-power was the Themistoclean instrument with which they made a small State into a great one.

Sea-power of Italian republics.

A fertile source of dispute between States is the acquisition of territory beyond sea. As others have done before and since, the maritime republics of Italy quarrelled over this. Sea-power seemed, like Saturn, to devour its own children. In 1284, in a great sea-fight off Meloria, the Pisans were defeated by the Genoese with heavy loss, which, as Sismondi states, "ruined the maritime power" of the former. From that time Genoa, transferring her activity to the Levant, became the rival of Venice. The fleets of the two cities in 1298 met near Cyprus in an encounter, said to be accidental, that began "a terrible war which for seven years stained the Mediterranean with blood and consumed immense wealth." In the next century the two republics, "irritated by commercial quarrels"—like the English and Dutch afterwards—were again at war in the Levant. Sometimes one side, sometimes the other was victorious; but the contest was exhausting to both, and especially to Venice. Within a quarter of a century they were at war again. Hostilities lasted till the Genoese met with the crushing defeat of Chioggia. "From this time," says Hallam, "Genoa never commanded the ocean with such navies as before; her commerce gradually went into decay; and the 15th century, the most splendid in the annals of Venice, is till recent times the most ignominious in those of Genoa." Venice seemed now to have no naval rival, and had no fear that any one could forbid the ceremony in which the Doge, standing in the bows of the *Bucentaur*, cast a ring into the Adriatic with the words, "*Desponsamus te, mare, in signum veri perpetuique dominii.*" The result of the combats at Chioggia, though fatal to it in the long run, did not at once destroy the naval importance of Genoa. A remarkable characteristic of sea-power is the delusive manner in which it appears to revive after a great defeat. The Persian navy occasionally made a brave show afterwards; but in reality it had received at Salamis a mortal wound. Athens seemed strong enough on the sea after the catastrophe of Syracuse; but, as already stated, her naval power had been given there a check from which it never completely recovered. The navy of Carthage had had similar experience; and, in later ages, the power of the Turks was broken at Lepanto and that of Spain at Gravelines notwithstanding deceptive appearances afterwards. Venice was soon confronted on the sea by a new rival. The Turkish naval historian, Haji Khalifeh (*Maritime Wars of the Turks*, Mitchell's trans., p. 12), tells us that, "After the taking of Constantinople, when they [the Ottomans] spread their conquests over land and sea, it became necessary to build ships and make armaments in order to subdue the fortresses and castles on the Rumelian and Anatolian shores, and in the islands of the Mediterranean." Mahommed II. established a great naval arsenal at Constantinople. In 1470 the Turks, "for the first time, equipped a fleet with which they drove that of the Venetians out of the Grecian seas" (Sismondi, p. 256). The Turkish wars of Venice lasted a long time. In that which ended in 1503 the decline of the Venetian naval power was obvious. "The Mussulmans had made progress in naval discipline; the Venetian fleet could no longer cope with theirs." Henceforward it was as an allied contingent of other navies that that of Venice was regarded as important. Dyer (*Hist. Europe*, i. p. 85) quotes a striking passage from a letter of Æneas Sylvius, afterwards Pope Pius II., in which the writer affirms that, "if the Venetians are defeated, Christendom will not control the sea any longer; for neither the Catalans nor the Genoese, without the Venetians, are equal to the Turks."

Sea-power and progress of the Turks.

The last-named people, indeed, exemplified once more the rule that a military State expanding to the sea and absorbing older maritime populations becomes a serious menace to its neighbours. Even in the 15th century Mahommed II. had made an attack on southern Italy; but his sea-power was not equal to the undertaking. Suleymân the Magnificent directed the Ottoman forces towards the west. With admirable strategic insight he conquered Rhodes, and thus freed himself from the danger of a hostile force on his flank. "The centenary of the conquest of Constantinople was past, and the Turk had developed a great naval power besides annexing Egypt and Syria" (Seeley, *British Policy*, i. p. 143). The Turkish fleets, under such leaders as Khair-ad-din (Barbarossa), Piale, and Dragut, seemed to command the Mediterranean including its western basin; but the repulse at Malta in 1565 was a serious check, and the defeat at Lepanto in 1571 virtually put an end to the prospect of Turkish maritime dominion. The predominance of Portugal in the Indian Ocean in the early part of the 16th century had seriously diminished the Ottoman resources. The wealth derived from the

trade in that ocean, the Persian Gulf, and the Red Sea, had supplied the Mahommedans with the sinews of war, and had enabled them to contend with success against the Christians in Europe. "The main artery had been cut when the Portuguese took up the challenge of the Mahommedan merchants of Calicut, and swept their ships from the ocean" (Whiteway, p. 2). The sea-power of Portugal wisely employed had exercised a great, though unperceived influence. However, though enfeebled and diminishing, the Turkish navy was still able to act with some effect in the 17th century. Nevertheless, the sea-power of the Turks ceased to count as a factor of importance in the relations between great States.

In the meantime the State which had a leading share in winning the victory of Lepanto had been growing up in the West. Before the union of its crown with that of Castile and the formation of the Spanish monarchy, Aragon had been expanding till it reached the sea. It was united with Catalonia in the 12th century, and it conquered Valencia in the 13th. Its long line of coast opened the way to an extensive and flourishing commerce; and an enterprising navy indemnified the nation for the scantiness of its territory at home by the important foreign conquests of Sardinia, Sicily, Naples, and the Balearic Isles. Among the maritime states of the Mediterranean Catalonia had been conspicuous. She was to the Iberian Peninsula much what Phœnicia had been to Syria. The Catalan navy had disputed the empire of the Mediterranean with the fleets of Pisa and Genoa. The incorporation of Catalonia with Aragon added greatly to the strength of that kingdom. The Aragonese kings were wise enough to understand and liberal enough to foster the maritime interests of their new possessions (Prescott, *Ferdinand and Isabella*, Introd. sects. i., ii.) Their French and Italian neighbours were to feel, before long, the effect of this policy; and, when the Spanish monarchy had been consolidated, it was felt not only by them, but by others also. The more Spanish dominion was extended in Italy the more were the naval resources at the command of Spain augmented. Genoa became "Spain's water-gate to Italy. . . . Henceforth the Spanish crown found in the Dorias its admirals; their squadron was permanently hired to the kings of Spain." Spanish supremacy at sea was established at the expense of France (G. W. Prothero, in M. Hume's *Spain, 1479–1788*, p. 65). The acquisition of a vast domain in the New World had greatly developed the maritime activity of Castile, and Spain was as formidable on the ocean as in the Mediterranean. After Portugal had been annexed the naval forces of that country were added to the Spanish, and the great port of Lisbon became available as a place of equipment and as an additional base of operations for oceanic campaigns. The fusion of Spain and Portugal, says Seeley, "produced a single State of unlimited maritime dominion. . . . Henceforth the whole New World belonged exclusively to Spain." The story of the tremendous catastrophe—the defeat of the Armada—by which the decline of this dominion was heralded is well known. It is memorable, not only because of the harm it did to Spain, but also because it revealed the rise of another claimant to maritime pre-eminence—the English nation. The effects of the catastrophe were not at once visible. Spain still continued to look like the greatest power in the world; and, though the English seamen were seen to be something better than adventurous pirates—a character suggested by some of their contemporary exploits—few could have comprehended that they were engaged in building up what was to be a sea-power greater than any known to history.

Spanish sea-power, Catalonia, &c.

They were carrying forward, not beginning, the building of this. "England," says Professor J. K. Laughton, "had always believed in her naval power, had always claimed the sovereignty of the Narrow Seas; and more than two hundred years before Elizabeth came to the throne, Edward III. had testified to his sense of its importance by ordering a gold coinage bearing a device showing the armed strength and sovereignty of England based on the sea" (*Armada*, Introd.) It is impossible to make intelligible the course of the many wars which the English waged with the French in the Middle Ages unless the true naval position of the former is rightly appreciated. Why were Créçy, Poitiers, Agincourt—not to mention other combats—fought, not on English, but on Continental soil? Why, during the so-called "Hundred Years' war," was England in reality the invader and not the invaded? We of the present generation are at last aware of the significance of naval defence, and know that, if properly utilized, it is the best security against invasion that a sea-surrounded State can enjoy. It is not, however, commonly remembered that the same condition of security existed and was properly valued in mediæval times. The battle of Sluys in 1340 rendered invasion of England as impracticable as did that of La Hogue in 1692, that of Quibéron Bay in 1759, and that of Trafalgar in 1805; and it permitted, as did those battles, the transport of troops to the Continent to support Great Britain's allies in wars which, had she not been strong at sea, would have been waged on the soil of her country. Her early Continental wars, therefore, are proofs of the long-established efficiency of her naval defences. Notwithstanding the greater attention now paid to naval affairs, it is doubtful if Great Britain even yet recognizes the extent to which her security depends upon a good fleet as fully as her ancestors did seven centuries ago. The narrative of pre-Elizabethan campaigns is interesting merely as a story; and, when told—as, for instance, D. Hannay has told it in the introductory chapters of his *Short History of the Royal Navy*—it will be found instructive and worthy of careful study at the present day. Each of the principal events in England's early naval campaigns may be taken as an illustration of the idea conveyed by the term "sea-power," and of the accuracy with which its meaning was apprehended at the time. To take a very early case, we may cite the defeat of Eustace the Monk by Hubert de Burgh in 1217. Reinforcements and supplies had been collected at Calais for conveyance to the army of Prince Louis of France and the rebel barons who had been defeated at Lincoln. The reinforcements tried to cross the Channel under the escort of a fleet commanded by Eustace. Hubert de Burgh, who had stoutly held Dover for King John, and was faithful to the young Henry III., heard of the enemy's movements. "If these people land," said he, "England is lost; let us therefore boldly meet them." He reasoned in almost the same words as Raleigh about four centuries afterwards, and undoubtedly "had grasped the true principles of the defence of England." He put to sea and defeated his opponent. The fleet on which Prince Louis and the rebellious barons had counted was destroyed; and with it their enterprise. "No more admirably planned, no more fruitful battle has been fought by Englishmen on water" (Hannay, p. 7). As introductory to a long series of naval operations undertaken with a like object it has deserved detailed mention here.

Early manifestations of British sea-power.

The 16th century was marked by a decided advance in both the development and the application of sea-power. Previously its operation had been confined to the Mediterranean or to coast waters outside it. Spanish or Basque seamen—by their proceedings in the English Channel—had proved the practicability of, rather than been engaged

in, ocean warfare. The English, who withstood them, were accustomed to seas so rough, to seasons so uncertain, and to weather so boisterous, that the ocean had few terrors for them. All that was wanting was a sufficient inducement to seek distant fields of action and a development of the naval art that would permit them to be reached. The discovery of the New World supplied the first; the consequently increased length of voyages and of absence from the coast led to the second. The world had been moving onwards in other things as well as in navigation. Intercommunication was becoming more and more frequent. What was done by one people was soon known to others. It is a mistake to suppose that, because the English had been behindhand in the exploration of remote regions they were wanting in maritime enterprise. The career of the Cabots would of itself suffice to render such a supposition doubtful. The English had two good reasons for postponing voyages to and settlement in far-off lands. They had their hands full nearer home; and they thoroughly, and as it were by instinct, understood the conditions on which permanent expansion must rest. They wanted to make sure of the line of communications first. To effect this a sea-going marine of both war and commerce, and, for further expansion, stations on the way were essential. The chart of the world furnishes evidence of the wisdom and the thoroughness of their procedure. Taught by the experience of the Spaniards and the Portuguese, when unimpeded by the political circumstances of the time, and provided with suitable equipment, the English displayed their energy in distant seas. It now became simply a question of the efficiency of sea-power. If this was not a quality of that of the English, then their efforts were bound to fail; and, more than this, the position of their country, challenging as it did what was believed to be the greatest of maritime States, would have been altogether precarious. The principal expeditions now undertaken were distinguished by a characteristic peculiar to the people, and not to be found in connexion with the exploring or colonizing activity of most other great nations even down to our own time. They were really unofficial speculations in which, if the Government took part at all, it was for the sake of the profit expected, and almost, if not exactly, like any private adventurer. The participation of the Government, nevertheless, had an aspect which it is worth while to note. It conveyed a hint—and quite consciously—to all whom it might concern that the speculations were "under-written" by the whole sea-power of England. The forces of more than one State had been used to protect its maritime trade from the assaults of enemies in the Mediterranean or in the Narrow Seas. They had been used to ward off invasion and to keep open communications across not very extensive areas of water. In the 16th century they were first relied upon to support distant commerce, whether carried on in a peaceful fashion or under aggressive forms. This, naturally enough, led to collisions. The contention waxed hot, and was virtually decided when the Armada shaped course to the northward after the fight off Gravelines.

Extending sphere of sea-power.

The expeditions against the Spanish Indies and, still more, those against Philip II.'s peninsular territory had helped to define the limitations of sea-power. It became evident, and it was made still more evident in the next century, that for a great country to be strong it must not rely upon a navy alone. It must also have an adequate and properly organized mobile army. Notwithstanding the number of times that this lesson has been repeated Great Britain has been slow to learn it. It is doubtful if she has learned it even yet. English seamen in all ages seem to have mastered it fully; for they have always demanded—at any rate for upwards of three centuries—that expeditions against foreign territory over-sea should be accompanied by a proper number of land-troops. On the other hand, the necessity of organizing the army of a maritime insular State and of training it with the object of rendering effective aid in operations of the kind in question, has rarely been perceived and acted upon by others. The result has been a long series of inglorious or disastrous affairs, like the West Indies voyage of 1595–96, the Cadiz expedition of 1625, and that to the Île de Ré of 1627. Additions might be made to the list. The failures of joint expeditions have often been explained by alleging differences or quarrels between the naval and the military commanders. This way of explaining them, however, is nothing but the inveterate critical method of the streets by which cause is taken for effect and effect for cause. The differences and quarrels arose, no doubt; but they generally sprang out of the recriminations consequent on, not producing, the want of success. Another manifestation of the way in which sea-power works was first observed in the 17th century. It suggested the adoption of, and furnished the instrument for, carrying out a distinct maritime policy. What was practically a standing navy had come into existence. As regards England this phenomenon was now of respectable age. Long voyages and cruises of several ships in company had been frequent during the latter half of the 16th century and the early part of the 17th. Even the grandfathers of the men who sailed with Blake and Penn in 1652 could not have known a time when ships had never crossed the ocean, and squadrons kept together for months had never cruised. However imperfect it may have been, a system of provisioning ships and supplying them with stores, and of preserving discipline among their crews, had been developed, and had proved fairly satisfactory. The Parliament and the Protector in turn found it necessary to keep a considerable number of ships in commission, and make them cruise and operate in company. It was not till well on in the reign of Queen Victoria that the man-of-war's man was finally differentiated from the merchant seaman; but, two centuries before, some of the distinctive marks of the former had already begun to be noticeable. There were seamen in the time of the Commonwealth who rarely, perhaps some who never, served afloat except in a man-of-war. Some of the interesting naval families which were settled at Portsmouth and the eastern ports, and which—from father to son—helped to recruit the ranks of bluejackets till a date later than that of the launch of the first ironclad, could carry back their professional genealogy to at least the days of Charles II., when, in all probability, it did not first start. Though landsmen continued even after the Civil War to be given naval appointments, and though a permanent corps, through the ranks of which every one must pass, had not been formally established, a body of real naval officers —men who could handle their ships, supervise the working of the armament, and exercise military command—had been formed. A navy, accordingly, was now a weapon of undoubted keenness, capable of very effective use by any one who knew how to wield it. Having tasted the sweets of intercourse with the Indies, whether in the occupation of Portugal or of Spain, both English and Dutch were desirous of getting a larger share of them. English maritime commerce had increased and needed naval protection. If England was to maintain the international position to which, as no one denied, she was entitled, that commerce must be permitted to expand.

Limitations of sea-power.

Appearance of standing navies.

Sea-power and territorial expansion in the "New World."

The minds of men in western Europe, moreover, were set upon obtaining for their country territories in the New World, the amenities of which were now known. From the reign of James I. the Dutch had shown great jealousy of English maritime enterprise. Where it was possible, as in the East Indian Archipelago, they had destroyed it. Their naval resources were great enough to let them hold English shipping at their mercy, unless a grand effort were made to protect it. The Dutch conducted the carrying trade of most of the world, and the monopoly of this they were resolved to keep, while the English were resolved to share in it. The exclusion of the English from every trade-route, except such as ran by their own coast or crossed the Narrow Seas, seemed a by no means impossible contingency. There seemed also to be but one way of preventing it, viz., by war. The supposed unfriendliness of the Dutch, or at least of an important party amongst them, to the regicide Government in England helped to force the conflict. The Navigation Act of 1651 was passed and regarded as a covert declaration of hostilities. So the first Dutch war began. It established England's claim to compete for the position of a great maritime commercial power.

Sea-power of the Dutch.

The rise of the sea-power of the Dutch, and the magnitude which it attained in a short time, and in the most adverse circumstances, have no parallel in history. The case of Athens was different, because the Athenian power had not so much been unconsciously developed out of a great maritime trade, as based on a military marine deliberately and persistently fostered during many years. Thirlwall believes that it was Solon who "laid the foundations of the Attic navy" (*Hist. Greece*, ii. p. 52), a century before Salamis. The great achievement of Themistocles was to convince his fellow-citizens that their navy ought to be increased. Perhaps the nearest parallel with the power of the Dutch was presented by that of Rhodes, which rested largely on a carrying trade. The Rhodian undertakings, however, were by comparison small and restricted in extent. Motley declares of the Seven United Provinces that they "commanded the ocean" (*United Netherlands*, ii. p. 132), and that it would be difficult to exaggerate the naval power of the young Commonwealth. Even in the days of Spain's greatness English seamen positively declined to admit that she was stronger than England on the sea; and the story of the Armada justified their view. The first two Dutch wars were, therefore, contests between the two foremost naval States of the world for what was primarily a maritime object. The identity of the cause of the first and of the second war will be discerned by any one who compares what has been said about the circumstances leading to the former, with Monk's remark as to the latter. He said that the English wanted a larger share of the trade enjoyed by the Dutch. It was quite in accordance with the spirit of the age that the Dutch should try to prevent, by force, this want from being satisfied. Anything like free and open competition was repugnant to the general feeling. The high road to both individual wealth and national prosperity was believed to lie in securing a monopoly. Merchants or manufacturers who called for the abolition of monopolies granted to particular courtiers and favourites had not the smallest intention, on gaining their object, of throwing open to the enterprise of all what had been monopolized. It was to be kept for the exclusive benefit of some privileged or chartered company. It was the same in greater affairs. As Mahan says, "To secure to one's own people a disproportionate share of the benefits of sea commerce every effort was made to exclude others, either by the peaceful legislative methods of monopoly or prohibitory regulations, or, when these failed, by direct violence." The apparent wealth of Spain was believed to be due to the rigorous manner in which foreigners were excluded from trading with the Spanish over-sea territories. The skill and enterprise of the Dutch having enabled them to force themselves into this trade, they were determined to keep it to themselves. The Dutch East India Company was a powerful body, and largely dictated the maritime policy of the country. We have thus come to an interesting point in the historical consideration of sea-power. The Elizabethan conflict with Spain had practically settled the question whether or not the expanding nations were to be allowed to extend their activities to territories in the New World. The first two Dutch wars were to settle the question whether or not the ocean trade of the world was to be open to any people qualified to engage in it. We can see how largely these were maritime questions, how much depended on the solution found for them, and how plain it was that they must be settled by naval means.

Effect on ocean trade.

Mahan's survey.

Mahan's great survey of sea-power opens in 1660, midway between the first and second Dutch wars. "The sailing-ship era, with its distinctive features," he tells us, "had fairly begun." The art of war by sea, in its more important details, had been settled by the first war. From the beginning of the second the general features of ship design, the classification of ships, the armament of ships, and the handling of fleets, were to remain without essential alteration until the date of Navarino. Even the tactical methods, except where improved on occasions by individual genius, altered little. The great thing was to bring the whole broadside force to bear on an enemy. Whether this was to be impartially distributed throughout the hostile line or concentrated on one part of it depended on the character of particular admirals. It would have been strange if a period so long and so rich in incidents had afforded no materials for forming a judgment on the real significance of sea-power. The text, so to speak, chosen by Mahan is that, notwithstanding the changes wrought in naval *matériel* since about 1850, we can find in the history of the past instructive illustrations of the general principles of maritime war. These illustrations will prove of value not only "in those wider operations which embrace a whole theatre of war," but also, if rightly applied, "in the tactical use of the ships and weapons" of our own day. By a remarkable coincidence the same doctrine was being preached at the same time and quite independently by the late Vice-Admiral Philip Colomb in his work on *Naval Warfare*. As a prelude to the second Dutch war we find a repetition of a process which had been adopted somewhat earlier. That was the permanent conquest of trans-oceanic territory. Until the 17th century had well begun, naval, or combined naval and military operations against the distant possessions of an enemy had been practically restricted to raiding or plundering attacks on commercial centres. The Portuguese territory in South America having come under Spanish dominion in consequence of the annexation of Portugal to Spain, the Dutch—as the power of the latter country declined—attempted to reduce part of that territory into permanent possession. This improvement on the practice of Drake and others was soon seen to be a game at which more than one could play. An expedition sent by Cromwell to the West Indies seized the Spanish island of Jamaica, which has remained in the hands of its conquerors to this day. In 1664 an English force occupied the Dutch North American settlements on the Hudson. Though the dispossessed rulers were not quite in a position to throw

stones at sinners, this was rather a raid than an operation of recognized warfare, because it preceded the formal outbreak of hostilities. The conquered territory remained in English hands for more than a century, and thus testified to the efficacy of a sea-power which Europe had scarcely begun to recognize. Neither the second nor the third Dutch war can be counted amongst the occurrences to which Englishmen may look back with unalloyed satisfaction; but they, unquestionably, disclosed some interesting manifestations of sea-power. Much indignation has been expressed concerning the corruption and inefficiency of the English Government of the day, and its failure to take proper measures for keeping up the navy as it should have been kept up. Some, perhaps a good deal, of this indignation was deserved; but it would have been nearly as well deserved by every other Government of the day. Even in those homes of political virtue where the administrative machinery was worked by, or in the interest of speculating capitalists and privileged companies, the accumulating evidence of late years has proved that everything was not considered to be, and as a matter of fact was not, exactly as it ought to have been. Charles II. and his brother, the duke of York, have been held up to obloquy because they thought that the coast of England could be defended against a naval enemy better by fortifications than by a good fleet and, as Pepys noted, were "not ashamed of it." The truth is that neither the king nor the duke believed in the power of a navy to ward off attack from an island. This may have been due to want of intellectual capacity; but it would be going a long way to put it down to personal wickedness. They have had many imitators, some in our own day. The huge forts which stud the coast of the United Kingdom, and have been erected within living memory, are monuments, likely to last for many years, of the inability of people, whom no one could accuse of being vicious, to rate sea-power at its proper value. It is much more likely that it was owing to a reluctance to study questions of naval defence as industriously as they deserved, and to that moral timidity which so often tempts even men of proved physical courage, to undertake the impossible task of making themselves absolutely safe against hostile efforts at every point.

Misapplication.

Charles II. has also been charged with indifference to the interests of his country, or worse, because during a great naval war he adopted the plan of trying to weaken the enemy by destroying his commerce. The king "took a fatal resolution of laying up his great ships and keeping only a few frigates on the cruise." It is expressly related, that this was not Charles's own idea, but that it was urged upon him by advisers whose opinion probably seemed at the time as well worth listening to as that of others. Anyhow if the king erred, as he undoubtedly did, he erred in good company. Fourteen hundred years earlier the statesmen who conducted the great war against Carthage, and whose astuteness has been the theme of innumerable panegyrics since, took the same "fatal resolution." In the midst of the great struggle they "did away with the fleet. At the most they encouraged privateering; and with that view placed the war-vessels of the State at the disposal of captains who were ready to undertake a corsair warfare on their own account" (Mommsen, ii. p. 52). In much later times this method has had many respectable defenders. Mahan's works are, in a sense, a formal warning to his fellow-citizens not to adopt it. In France, within the last years of the 19th century, it found, and appears still to find, adherents enough to form a school. The reappearance of belief in demonstrated impossibilities is a recognized incident in human history; but it is usually confined to the emotional or the vulgar. It is serious and filled with menaces of disaster when it is held by men thought fit to administer the affairs of a nation or advise concerning its defence. The third Dutch war may not have settled directly the position of England in the maritime world; but it helped to place that country above all other maritime States—in the position, in fact, which Great Britain, the United Kingdom, the British Empire, whichever name may be given it, has retained up to the present. It also manifested in a very striking form the efficacy of sea-power. The United Provinces, though attacked by two of the greatest monarchies in the world, France and England, were not destroyed. Indeed, they preserved much of their political importance in the State system of Europe. The Republic "owed this astonishing result partly to the skill of one or two men, but mainly to its sea-power." The effort, however, had undermined its strength and helped forward its decline.

The war which was ended by the Peace of Ryswick in 1697 presents two features of exceptional interest: one was the havoc wrought on English commerce by the enemy; the other was Torrington's conduct at and after the engagement off Beachy Head. Mahan discusses the former with his usual lucidity. At no time has war against commerce been conducted on a larger scale and with greater results than during this period. England suffered "infinitely more than in any former war." Many of her merchants were ruined; and it is affirmed that the English shipping was reduced to the necessity of sailing under the Swedish and Danish flags. The explanation is that Louis XIV. made great efforts to keep up powerful fleets. The English navy was so fully occupied in watching these that no ships could be spared to protect England's maritime trade. This is only another way of saying that her commerce had increased so largely that the navy was not strong enough to look after it as well as oppose the enemy's main force. Notwithstanding her losses she was on the winning side in the conflict. Much misery and ruin had been caused, but not enough to affect the issue of the war.

The "Fleet in being."

Torrington's proceedings in July 1690 were at the time the subject of much angry discussion. The debate, still meriting the epithet angry, has been renewed within the last few years. The matter has to be noticed here, because it involves the consideration of a question of naval strategy which must be understood by those who wish to know the real meaning of the term sea-power, and who ought to learn that it is not a thing to be idly risked or thrown away at the bidding of the ignorant and the irresponsible. Arthur Herbert, earl of Torrington — the later peerage is a viscountcy held by the Byng family—was in command of the allied English and Dutch fleet in the English Channel. "The disparity of force," says Mahan, "was still in favour of France in 1690, but it was not so great as the year before." We can measure the ability of the then English Government for conducting a great war, when we know that, in its wisdom, it had still further weakened the fleet by dividing it. Vice-Admiral Killigrew had been sent to the Mediterranean with a squadron, and had neglected, and indeed refused when urged, to take the necessary steps to repair this error. The Government having omitted, as Governments sometimes do, to gain any trustworthy intelligence of the strength or movements of the enemy, Torrington suddenly found himself confronted by a considerably superior French fleet under Tourville, one of the greatest of French sea-officers. Since then the intentions of the French have been questioned; but it is beyond dispute that, in England at the time, Tourville's movements were believed to be preliminary to invasion. Whether

Tourville deliberately meant his movement to cover an invasion or not, invasion would almost certainly have followed complete success on his part; otherwise, his victory would have been without any valuable result. Torrington saw that as long as he could keep his own fleet intact, he could, though much weaker than his opponent, prevent him from doing serious harm. Though personally not a believer in the imminence of invasion, the English admiral knew that "most men were in fear that the French would invade." His own view was, "that whilst we had a fleet in being they would not dare to make an attempt." Of late years controversy has raged round this phrase, "a fleet in being" and the strategic principle which it expresses. Most seamen were at the time, have been since, and still are in agreement with Torrington. This might be supposed enough to settle the question. It has not been allowed, however, to remain one of purely naval strategy. It was made at the time a matter of party politics. This is why it is so necessary that in a notice of sea-power it should be discussed. Both as a strategist and as a tactician Torrington was immeasurably ahead of his contemporaries. The only English admirals who can be placed above him are Hawke and Nelson. He paid the penalty of his pre-eminence: he could not make ignorant men and dull men see the meaning or the advantages of his proceedings. Mahan, who is specially qualified to do him full justice, does not devote much space in his work to a consideration of Torrington's case, evidently because he had not sufficient materials before him on which to form a judgment. The admiral's character had been taken away already by Macaulay, who did have ample evidence before him. William III., with all his fine qualities, did not possess a military genius quite equal to that of Napoleon; and Napoleon, in naval strategy, was often wrong. William III. understood that subject even less than the French emperor did; and his favourites were still less capable of understanding it. Consequently Torrington's action has been put down to jealousy of the Dutch. There have been people who accused Nelson of being jealous of the naval reputation of Caracciolo! The explanation of Torrington's conduct is this:—He had a fleet so much weaker than Tourville's that he could not fight a general action with the latter without a practical certainty of a crushing defeat. Such a result would have laid the kingdom open: a defeat of the allied fleet, says Mahan, "if sufficiently severe, might involve the fall of William's throne in England." Given certain movements of the French fleet, Torrington might have manœuvred to slip past it to the westward and join his force with that under Killigrew, which would make him strong enough to hazard a battle. This proved impracticable. There was then one course left—retire before the French, but not to keep far from them. He knew that, though not strong enough to engage their whole otherwise unemployed fleet with any hope of success, he would be quite strong enough to fight and most likely beat it, when a part of it was trying either to deal with our ships to the westward or to cover the disembarkation of an invading army. He, therefore, proposed to keep his "fleet in being" in order to fall on the enemy when the latter would have two affairs at the same time on his hands. The late Vice-Admiral Colomb rose to a greater height than was usual even with him in his criticism of this campaign. What Torrington did was merely to reproduce on the sea what has been noticed dozens of times on shore, viz., the menace of the flanking enemy. In land warfare this is held to give exceptional opportunities for the display of good generalship, but, to quote Mahan over again, a navy "acts on an element strange to most writers, its members have been from time immemorial a strange race apart, without prophets of their own, neither themselves nor their calling understood." Whilst Torrington has had the support of seamen, his opponents have been landsmen. For the crime of being a good strategist he was brought before a court-martial, but acquitted. His sovereign, who had been given the crowns of three kingdoms to defend our laws, showed his respect for them by flouting a legally constituted tribunal and disregarding its solemn finding. The admiral who had saved his country was dismissed from the service. Still, the principle of the "fleet in being" lies at the bottom of all sound strategy.

Change in naval operations

Admiral Colomb has pointed out a great change of plan in the later naval campaigns of the 17th century. Improvements in naval architecture, in the methods of preserving food, and in the arrangements for keeping the crews healthy, permitted fleets to be employed at a distance from their home ports for long continuous periods. The Dutch, as allies of the Spaniards, kept a fleet in the Mediterranean for many months. The great de Ruyter was mortally wounded in one of the battles there fought. In the war of the Spanish Succession the Anglo-Dutch fleet found its principal scene of action eastward of Gibraltar. This, as it were, set the fashion for future wars. It became a kind of tacitly accepted rule that the operation of British sea-power was to be felt in the enemy's, rather than in British waters. The hostile coast was regarded strategically as the British frontier, and the sea was looked upon as territory which the enemy must be prevented from invading. Acceptance of this principle led in time to the so-called "blockades" of Brest and Toulon. The name was misleading. As Nelson took care to explain, there was no desire to keep the enemy's fleet in; what was desired was to be near enough to attack it if it came out. The wisdom of the plan is undoubted. The hostile navy could be more easily watched and more easily followed if it put to sea. To carry out this plan a navy stronger in number of ships or in general efficiency than that of the enemy was necessary. With the exception of that of American Independence, which will therefore require special notice, England's subsequent great wars were conducted in accordance with the rule.

Rise of Russia's sea-power.

In the early part of the 18th century there was a remarkable manifestation of sea-power in the Baltic. Peter the Great, having created an efficient army, drove the Swedes from the coast provinces south of the Gulf of Finland. Like the earlier monarchies of which we have spoken, Russia, in the Baltic at least, now became a naval State. A large fleet was built, and, indeed, a considerable navy established. It was a purely artificial creation, and showed the merits and defects of its character. At first, and when under the eye of its creator, it was strong; when Peter was no more it dwindled away and, when needed again, had to be created afresh. It enabled Peter the Great to conquer the neighbouring portion of Finland, to secure his coast territories, and to dominate the Baltic. In this he was assisted by the exhaustion of Sweden consequent on her endeavours to retain, what was no longer possible, the position of a *quasi*-great Power which she had held since the days of Gustavus Adolphus. Sweden had been further weakened, especially as a naval State, by almost incessant wars with Denmark, which prevented all hope of Scandinavian predominance in the Baltic, the control of which sea has in these days passed into the hands of another State possessing a quickly created navy—the modern German empire.

The war of the Spanish Succession left Great Britain a Mediterranean power, a position which, in spite of twice losing Minorca, she still holds. In the war of the Austrian

Succession, "France was forced to give up her conquests for want of a navy, and England saved her position by her sea-power, though she had failed to use it to the best advantage" (Mahan, *Influence on Hist.* p. 280). This shows, as we shall find that a later war showed more plainly, that even the Government of a thoroughly maritime country is not always sure of conducting its naval affairs wisely. The Seven Years' war included some brilliant displays of the efficacy of sea-power. It was this which put the British in possession of Canada, decided which European race was to rule in India, and led to a British occupation of Havana in one hemisphere and of Manila in the other. In the same war Great Britain learnt how, by a feeble use of sea-power, a valuable possession, like Minorca, may be lost. At the same time, the maritime trade and the general prosperity of the kingdom increased enormously. The result of the conflict made plain to all the paramount importance of having in the principal posts in the Government men capable of understanding what war is and how it ought to be conducted.

Seven Years' War.

This lesson, as the sequel demonstrated, had not been learned when Great Britain became involved in a war with the insurgent colonies in North America. Mahan's comment is striking: "The magnificence of sea-power and its value had perhaps been more clearly shown by the uncontrolled sway and consequent exaltation of one belligerent; but the lesson thus given, if more striking, is less vividly interesting than the spectacle of that sea-power meeting a foe worthy of its steel, and excited to exertion by a strife which endangered not only its most valuable colonies, but even its own shores" (*Influence on Hist.* p. 338). Great Britain was, in fact, drawing too largely on the *prestige* acquired during the Seven Years' war, and was governed by men who did not understand the first principles of naval warfare, and would not listen to those who did. They quite ignored the teaching of the then comparatively recent wars which has been alluded to already—that the enemy's coast should be looked upon as the frontier. A century and a half earlier the Dutchman Grotius had written—

First American War.

Quæ meta Britannis
Litora sunt aliis.

Though ordinary prudence would have suggested ample preparation, British ministers allowed their country to remain unprepared. Instead of concentrating their efforts on the main objective, they frittered away force in attempts to relieve two beleaguered garrisons under the pretext of yielding to popular pressure, which is the official term for acting on the advice of irresponsible and uninstructed busybodies. "Depuis le débût de la crise," says Captain Chevalier, "les ministres de la Grande Bretagne s'étaient montrés inférieurs à leur tâche." An impressive result of this was the repeated appearance of powerful and indeed numerically superior hostile fleets in the English Channel. The war—notwithstanding that, perhaps because, land operations constituted an important part of it, and in the end settled the issue—was essentially oceanic. Captain Mahan says it was "purely maritime." It may be true that, whatever the belligerent result, the political result, as regards the *status* of the insurgent colonies, would have been the same. It is in the highest degree probable, indeed it closely approaches to certainty, that a proper use of the British sea-power would have prevented independence from being conquered, as it were, at the point of the bayonet. There can be no surprise in store for the student acquainted with the vagaries of strategists who are influenced in war by political in preference to military requirements. Still, it is difficult to repress an emotion of astonishment on finding that a British Government intentionally permitted de Grasse's fleet and the French army in its convoy to cross the Atlantic unmolested, for fear of postponing for a time the revictualling of the garrison beleaguered at Gibraltar. Washington's opinion as to the importance of the naval factor has been quoted already; and Mahan does not put the case too strongly when he declares that the success of the Americans was due to "sea-power being in the hands of the French and its improper distribution by the English authorities." England's navy, misdirected as it was, made a good fight of it, never allowed itself to be decisively beaten in a considerable battle, and won at least one great victory. At the point of contact with the enemy, however, it was not in general so conspicuously successful as it was in the Seven Years' war, or as it was to be in the great conflict with the French republic and empire. The truth is that its opponent, the French navy, was never so thoroughly a sea-going force as it was in the war of American Independence; and never so closely approached the British in sea-experience as it did during that period. Great Britain met antagonists who were very nearly, but fortunately not quite, as familiar with the sea as she was; and she never found it so hard to beat them, or even to avoid being beaten by them. An Englishman would, naturally enough, start at the conclusion confronting him, if he were to speculate as to the result of more than one battle had the great Suffren's captains and crews been quite up to the level of those commanded by stout old Sir Edward Hughes. Suffren, it should be said, before going to the East Indies, had "thirty-eight years of almost uninterrupted sea-service" (Laughton, *Studies in Naval Hist.* p. 103). A glance at a chart of the world, with the scenes of the general actions of the war dotted on it, will show how notably oceanic the campaigns were. The hostile fleets met over and over again on the far side of the Atlantic and in distant Indian seas. The French navy had penetrated into the ocean as readily and as far as the British could do. Besides this, it should be remembered that it was not until the 12th April 1782, when Rodney in one hemisphere and Suffren in the other showed them the way, that British officers were able to escape from the fetters imposed on them by the *Fighting Instructions*—a fact worth remembering in days in which it is sometimes proposed, by establishing schools of naval tactics on shore, to revive the pedantry which made a decisive success in battle nearly impossible.

The mighty conflict which raged between Great Britain on one side and France and her allies on the other, with little intermission, for more than twenty years, presents a different aspect from that of the war last mentioned. The victories which the British fleet was to gain were generally to be overwhelming; if not, they were looked upon as almost defeats. Whether the fleet opposed to the British was or was not the more numerous, the result was generally the same—the enemy was beaten. That there was a discoverable reason for this is certain. A great deal has been made of the disorganization in the French navy consequent on the confusion of the Revolution. That there was disorganization is undoubted; that it did impair discipline and, consequently, general efficiency will not be disputed; but that it was considerable enough to account by itself for the French naval defeats is altogether inadmissible. Revolutionary disorder had invaded the land-forces to a greater degree than it had invaded the sea-forces. The supersession, flight, or guillotining of army officers had been beyond measure more frequent than was the case with the naval officers. In spite of all this the French armies were on the whole—even in the

Wars of the French Revolution and Empire.

early days of the Revolution—extraordinarily successful. In 1792 "the most formidable invasion that ever threatened France," as Alison calls it, was repelled, though the invaders were the highly-disciplined and veteran armies of Prussia and Austria. It was nearly two years later that the French and British fleets came into serious conflict. The first great battle, "The Glorious First of June," though a tactical victory for Great Britain, was a strategical defeat. Villaret Joyeuse manœuvred so as to cover the arrival in France of a fleet of merchant vessels carrying sorely-needed supplies of food, and in this he was completely successful. His plan involved the probability, almost the necessity of fighting a general action which he was not at all sure of winning. He was beaten, it is true; but the French made so good a fight of it that their defeat was not nearly so disastrous as the later defeats of the Nile or Trafalgar, and—at the most—not more disastrous than that of Dominica. Yet no one even alleges that there was disorder or disorganization in the French fleet at the date of any one of those affairs. Indeed, if the French navy was really disorganized in 1794, it would have been better for France—judging from the events of 1798 and 1805—if the disorganization had been allowed to continue. In point of organization the British navy was inferior, and in point of discipline not much superior to the French at the earliest date; at the later dates, and especially at the latest, owing to the all-pervading energy of Napoleon, the British was far behind its rival in organization, in "science," and in every branch of training that can be imparted without going to sea. Great Britain had the immense advantage of counting among her officers some very able men. Nelson, of course, stands so high that he holds a place entirely by himself. The other British chiefs, good as they were, were not conspicuously superior to the Hawkes and Rodneys of an earlier day. Howe was a great commander, but he did little more than just appear on the scene in the Revolutionary war. Almost the same may be said of Hood, of whom Nelson wrote, "He is the greatest sea-officer I ever knew" (Laughton, *Nelson's Lett. and Desp.* p. 71). There must have been something, therefore, beyond the meritorious qualities of the principal British officers which helped the navy so consistently to victory. The many triumphs won could not have been due in every case to the individual superiority of the British admiral or captain to his opponent. There must have been bad as well as good among the hundreds on the lists; and we cannot suppose that Providence had so arranged it that in every action in which a British officer of inferior ability commanded, a still more inferior French commander was opposed to him.

Importance of sea-experience.

The explanation of the nearly unbroken success is, that the British was a thoroughly sea-going navy, and became more and more so every month; while the French, since the close of the American war, had lost to a great extent its sea-going character and, because it had been shut up in its ports, became less and less sea-going as hostilities continued. The war had been for the British, in the words of President Roosevelt, "a continuous course of victory won mainly by seamanship." The British navy, as regards sea-experience, especially of the officers, was immensely superior to the French. This enabled the British Government to carry into execution sound strategic plans, in accordance with which the coasts of France and its allied countries were regarded as the British frontier to be watched or patrolled by British fleets.

Before the long European war had been brought to a formal ending we received some rude rebuffs from another opponent of unsuspected vigour. In the quarrel with the United States, the so-called "War of 1812," the great sea-power of the British in the end asserted its influence, and the Americans suffered much more severely, even absolutely, than their enemy.

Second American War.

At the same time the British might have learned, for the Americans did their best to teach it, that over-confidence in numerical strength and narrow professional self-satisfaction are nearly sure to lead to reverses in war, and not unlikely to end in grave disasters. The British had now to meet the *élite* of one of the finest communities of seamen ever known. Even in 1776 the Americans had a great maritime commerce, which, as Mahan says, "had come to be the wonder of the statesmen of the mother country." In the six-and-thirty years which had elapsed since then this commerce had further increased. There was no finer nursery of seamen than the then states of the American Union. Roosevelt says that "there was no better seaman in the world" than the American, who "had been bred to his work from infancy." A large proportion of the population "was engaged in sea-going pursuits of a nature strongly tending to develop a resolute and hardy character in the men that followed them" (*Naval War of 1812*, 3rd ed., pp. 29, 30). Having little or no naval protection, the American seaman had to defend himself in many circumstances, and was compelled to familiarize himself with the use of arms. The men who passed through this practical, and therefore supremely excellent training school were numerous. Very many had been trained in English men-of-war, and some in French ships. The State navy which they were called on to man was small; and therefore its *personnel*, though without any regular or avowed selection, was virtually and in the highest sense a picked body. The lesson of the war of 1812 should be learned by Englishmen of the present day, when a long naval peace has generated a confidence in numerical superiority, in the mere possession of heavier *matériel*, and in the merits of a rigidly uniform system of training, such confidence, as experience has shown, being often the forerunner of misfortune. It is neither patriotic nor intelligent to minimize the American successes. Certainly they have been exaggerated by Americans and even by the British. To take the frigate actions alone, as being those which properly attracted most attention, the captures in action amounted to three on each side, the proportionate loss to the Americans, considering the smallness of their fleet, being immensely greater than to the British. We also see that no British frigate was taken after the first seven months of a war which lasted two and a half years. Attempts have been made to spread a belief that British reverses were due to nothing but the greater size and heavier guns of the enemy's ships. It is now established that the superiority in these details, which the Americans certainly enjoyed, was not great, and not of itself enough to account for their victories. Of course, if superiority in mere *matériel*, beyond a certain well-understood amount, is possessed by one of two combatants, his antagonist can hardly escape defeat; but it was never alleged that size of ship or calibre of guns—greater within reasonable limits than the British had—necessarily led to the defeat of British ships by the French or Spaniards. In the words of Admiral Jurien de la Gravière, "the ships of the United States constantly fought with the chances in their favour." All this is indisputable. Nevertheless in any future war British sea-power, great as it may be, should not receive shocks like those that it unquestionably did suffer in 1812.

We have now come to the end of the days of the naval wars of the past. The subsequent period has been illustrated repeatedly by manifestations of sea-power, often of great interest and importance, though rarely understood

or even discerned by the nations whom they more particularly concerned. The British sea-power, notwithstanding the first year of the war of 1812, had come out of the great European conflict unshaken and indeed more pre-eminent than ever. The words used half a century before by a writer in the great French *Encyclopédie*, seemed more exact than when first written. "*L'empire des mers*," he says, is "le plus avantageux de tous les empires; les Phœniciens le possédoient autre fois et c'est aux Anglois que cette gloire appartient aujourd'hui sur toutes les puissances maritimes" (*Encyclopédie*, 7th January 1765, art. "Thalassarchie"). Vast outlying territories had been acquired or were more firmly held, and the communications of all the over-sea dominions of the British crown were secured against all possibility of serious menace for many years to come. Her sea-power was so ubiquitous and all-pervading that, like the atmosphere, Great Britain rarely thought of it and rarely remembered its necessity or its existence. It was not till a late date that the greater part of the nation—for there still are some exceptions—perceived that it was the medium apart from which the British empire could no more live than it could have grown up. Forty years after the fall of Napoleon she found herself again at war with a great Power. She had as her ally the owner of the greatest navy in the world except her own. Her foe, as regards his naval forces, came the next in order. Yet so overwhelming was the strength of Great Britain and France on the sea that Russia never attempted to employ her navy against them. Not to mention other expeditions, considerable enough in themselves, military operations on the largest scale were undertaken, carried on for many months, and brought to a successful termination on a scene so remote that it was two thousand miles from the country of one, and three thousand from that of the other partner in the alliance. "The stream of supplies and reinforcements, which in terms of modern war is called 'communications,'" was kept free from even the threat of molestation, not by visible measures, but by the undisputed efficacy of a real, though imperceptible sea-power. At the close of the Russian war there were, even in influential positions, men who, undismayed by the consequences of mimicking in free England the cast-iron methods of Frederick the Great, began to measure British requirements by standards borrowed from abroad and altogether inapplicable to British conditions. Because other countries wisely abstained from relying on that which they did not possess, or had only imperfectly and with elaborate art created, the mistress of the seas was led to proclaim her disbelief in the very force that had made and kept her dominion, and was urged to defend herself with fortifications by advisers who, like Charles II. and the duke of York two centuries before, were "not ashamed of it." It was long before the peril into which this brought the empire was perceived; but at last, and in no small degree owing to the teachings of Mahan, the people themselves took the matter in hand and insisted that a great maritime empire should have adequate means of defending all that made its existence possible.

Russian War, 1854-56.

In forms differing in appearance, but identical in essentials, the efficacy of sea-power was proved again in the American Civil War. If ever there were hostilities in which, to the unobservant or short-sighted, naval operations might at first seem destined to count for little they were these. The sequel, however, made it clear that they constituted one of the leading factors of the success of the victorious side. The belligerents, the Northern or Federal states and the Southern or Confederate states, had a common land frontier of great length. The capital of each section was within easy distance of this frontier, and the two were not far apart. In wealth, population, and resources the Federals were enormously superior. They alone possessed a navy, though at first it was a small one. The one advantage on the Confederate side was the large proportion of military officers which belonged to it and their rare excellence as soldiers. In *physique* as well as in *morale* the army of one side differed little from that of the other; perhaps the Federal army was slightly superior in the first, and the Confederate, as being recruited from a dominant white race, in the second. Outnumbered, less well equipped, and more scantily supplied, the Confederates nevertheless kept up the war, with many brilliant successes on land, for four years. Had they been able to maintain their trade with neutral States they could have carried on the war longer, and—not improbably—have succeeded in the end. The Federal navy, which was largely increased, took away all chance of this. It established effective blockades of the Confederate ports, and severed their communications with the outside world. Indispensable articles of equipment could not be obtained, and the armies, consequently, became less and less able to cope with their abundantly furnished antagonists. By dominating the rivers the Federals cut the Confederacy asunder; and by the power they possessed of moving troops by sea at will, perplexed and harassed the defence, and facilitated the occupation of important points. Meanwhile the Confederates could make no reply on the water except by capturing merchant vessels, by which the contest was embittered, but the course of the war remained absolutely unaffected. The great numbers of men under arms on shore, the terrific slaughter in many battles of a war in which tactical ability, even in a moderate degree, was curiously uncommon on both sides, and the varying fortunes of the belligerents, made the land campaigns far more interesting to the ordinary observer than the naval. It is not surprising, therefore, that peace had been re-established for several years before the American people could be made to see the great part taken by the navy in the restoration of the Union; and what the Americans had not seen was hidden from the sight of other nations.

Later manifestations of sea-power.

In several momentous wars in Europe waged since France and Great Britain made peace with Russia sea-power manifested itself but little. In the Russo-Turkish war the naval superiority of the Turks in the Black Sea, where the Russians at the time had no fleet, governed the plans, if not the course, of the campaigns. The water being denied to them, the Russians were compelled to execute their plan of invading Turkey by land. An advance to the Bosphorus through the northern part of Asia Minor was impracticable without help from a navy on the right flank. Consequently the only route was a land one across the Danube and the Balkans. The advantages, though not fully utilized, which the enforcement of this line of advance put into the hands of the Turks, and the difficulties and losses which it caused the Russians, exhibited in a striking manner what sea-power can effect even when its operation is scarcely observable.

Russo-Turkish War, 1877-78.

This was more conspicuous in a later series of hostilities. The civil war in Chile between Congressists and Balmacedists was specially interesting, because it threw into sharp relief the predominant influence, when a non-maritime enemy was to be attacked, of a navy followed up by an adequate land-force. At the beginning of the dispute the Balmacedists, or President's party, had practically all the army, and the Congressists, or Opposition party, nearly all the Chilian navy. Unable to remain in the principal province of the republic, and expelled from the waters of Valparaiso by

Chilian Civil War, 1891.

the Balmacedist garrisons of the forts—the only and doubtful service which those works rendered to their own side—the Congressists went off with the ships to the northern provinces, where they counted many adherents. There they formed an army, and having money at command, and open sea communications, they were able to import equipment from abroad, and eventually to transport their land-force, secured from molestation on the voyage by the sea-power at their disposal, to the neighbourhood of Valparaiso, where it was landed and triumphantly ended the campaign.

It will have been noticed that, in its main outlines, this story repeated that of many earlier struggles. It was itself repeated, as regards its general features, by the story of the war between China and Japan in 1894–95. Every aspect of the war, says Colomb, is interesting to Great Britain, "as Japan is to China in a position similar to that which the British Islands occupy to the European continent" (*Naval Warfare*, 3rd ed., p. 436). It was additionally interesting because the sea-power of Japan was a novelty. Though a novelty, it was well known by British naval men to be superior in all essentials to that of China, a novelty itself. As is the rule when two belligerents are contending for something beyond a purely maritime object, the final decision was to be on land. Korea was the principal theatre of the land war; and, as far as access to it by sea was concerned, the chief bases of the two sides were about the same distance from it. It was possible for the Chinese to march there by land. The Japanese, coming from an island State, were obliged to cross the water. It will be seen at once that not only the success of the Japanese in the struggle, but also the possibility of its being carried on by them at all, depended on sea-power. The Japanese proved themselves decisively superior at sea. Their navy effectually cleared the way for one army which was landed in Korea, and for another which was landed in the Chinese province of Shantung. The Chinese land-forces were defeated. The navy of Japan being superior on the sea, was able to keep its sister service supplied or reinforced as required. It was not, however, the navy, but the army, which finally frustrated the Chinese efforts at defence, and really terminated the war. What the navy did was what, in accordance with the limitations of sea-power, may be expected of a navy. It made the transport of the army across the sea possible; and enabled it to do what of itself the army could not have done, viz., overcome the last resistance of the enemy.

War between China and Japan, 1894-95.

The issue of the Spanish-American war, at least as regards the defeat of Spain, was a foregone conclusion. That Spain, even without a serious insurrection on her hands, was unequal to the task of meeting so powerful an antagonist as the United States must have been evident even to Spaniards. However that may be, an early collapse of the Spanish defence was not anticipated, and however one-sided the war may have been seen to be, it furnished examples illustrating rules as old as naval warfare. Mahan says of it that, "while possessing, as every war does, characteristics of its own differentiating it from others, nevertheless in its broad analogies it falls into line with its predecessors, evidencing that unity of teaching which pervades the art from its beginnings unto this day" (*Lessons of the War with Spain*, p. 16). The Spaniards were defeated by the superiority of the American sea-power. "A million of the best soldiers," says Mahan, "would have been powerless in face of hostile control of the sea." That control was obtained and kept by the United States navy, thus permitting the unobstructed despatch of troops—and their subsequent reinforcement and supply—to Spanish territory, which was finally conquered, not by the navy, but by the army on shore. That it was the navy which made this final conquest possible happened, in this case, to be made specially evident by the action of the United States Government, which stopped a military expedition on the point of starting for Cuba until the sea was cleared of all Spanish naval force worth attention.

Spanish-American War, 1898.

The events of the long period which we have been considering will have shown how sea-power operates, and what it effects. What it involves will have appeared from this narrative more clearly than would have been possible from any mere definition. Like many other things, sea-power is composed of several elements. To reach the highest degree of efficacy it should be based upon a population naturally maritime, and on an ocean commerce naturally developed rather than artificially enticed to extend itself. Its outward and visible sign is a navy, strong in the discipline, skill, and courage of a numerous *personnel* habituated to the sea, in the number and quality of its ships, in the excellence of its *matériel*, and in the efficiency, scale, security, and geographical position of its arsenals and bases. History has demonstrated that sea-power thus conditioned can gain any purely maritime object, can protect the trade and the communications of a widely-extended empire, and while so doing can ward off from its shores a formidable invader. There are, however, limitations to be noted. Left to itself its operation is confined to the water, or at any rate to the inner edge of a narrow zone of coast. It prepares the way for the advance of an army, the work of which it is not intended, and is unable to perform. Behind it, in the territory of which it guards the shores, there must be a land-force adjusted in organization, equipment, and numbers to the circumstances of the country. The possession of a navy does not permit a sea-surrounded State to dispense with all fixed defences or fortification; but it does render it unnecessary and indeed absurd that they should be abundant or gigantic. The danger which always impends over the sea-power of any country is that, after being long unused, it may lose touch of the sea. The revolution in the constructive arts during the latter half of the 19th century, which has also been a period of but little-interrupted naval peace, and the universal adoption of mechanical appliances, both for ship-propulsion and for many minor services—mere *matériel* being thereby raised in the general estimation far above really more important matters—makes the danger mentioned more menacing in the present age than it has ever been before. (C. A. G. B.)

Seattle, a city and seaport of Washington, U.S.A., capital of King county. It is situated in 47° 36′ N. and 122° 20′ W., on the east shore of Elliott Bay, an arm of Puget Sound. Its site rises steeply from the water to a summit and descends eastwards to Lake Washington. On this site the city is laid out with much regularity on the whole, and is divided into nine wards. It has an excellent water-supply and is well sewered, but few of the streets are paved. Among its fine buildings are Providence hospital, the court house, opera house, high school, and many business blocks. It has seven public parks, besides Lake Washington, behind the city, a sheet of water 25 miles long, with very wild, picturesque shores. Seattle is the largest city of Washington and one of the busiest and most active of the North-West. It is an important commercial port of Puget Sound, having lines of steamers to Asiatic ports, to San Francisco, and to Alaska. It has also a large trade with other Puget Sound ports by small steamers. Here is the Pacific coast terminus of the

Great Northern Railway, and one of the termini of the Northern Pacific Railway. The Columbia and Puget Sound and the Seattle and International railways also enter the city. Seattle has also large manufacturing interests. In 1900 it contained 953 manufacturing establishments, with a total capital of $10,131,651. These employed 8480 hands, and their product was valued at $26,373,402. Of the various products, lumber, including planing-mill products, had a value of $2,846,558; slaughtering and meat-packing, a value of $3,072,195; foundry and machine-shop, and flouring and grist mill products, canning and preserving fish, and the products of the building trades were also large. This city is the seat of the state university, a non-sectarian institution, opened in 1862, which in 1899 had a faculty of 27 and was attended by 264 students, 122 of whom were women. The assessed valuation of real and personal property was, in 1900, $40,148,265, the net-debt was $5,410,755, and the rate of taxation was $25.50 per $1000. Seattle was founded in 1852, receiving the name of an Indian chief, and for many years had a slow growth, having in 1880 a population of only 3533. The rapid development of the lumber industry in this part of the state was mainly responsible for the tremendous stride which the city took in the ten years following, resulting in a population in 1890 of 42,837. In 1900 the population was returned as 80,671, of whom 22,003 were foreign-born and 3856 coloured, including 406 negroes. Of 39,503 males 21 years of age and over, 598 were illiterate (unable to write). In 1889 the business part of the city was almost entirely burned.

Sebastopol, a district town and military seaport of Russia, in the government of Taurida, in the south-west of the Crimea, in 44° 37′ N. and 33° 31′ E., 947 miles by rail from Moscow. Since it was connected with the Russian railway system, a new town has rapidly grown on the ruins which were left after the famous siege it sustained during the Crimean war, and in 1897 it contained 50,710 inhabitants, of whom only 18,661 were women. The town is well built and is becoming a favourite watering-place on account of its sea-bathing and numerous sanatoria. It has three libraries, two newspapers, gymnasia for boys and girls, and two navigation schools. It was at one time hoped that it would become an important commercial seaport; its exports rapidly grew from 1885 to 1889, when they totalled as much as 370,000 tons, but in the year 1890 Sebastopol was made a fortress of the third class, and the commercial port has been transported to Theodosia.

Sebenico, a coast town on the Adriatic, in the Austrian province of Dalmatia, in about 43° 44′ N., nearly midway between Zara and Spalato. Population of town (1890), 7014, and of commune, 20,360, chiefly Serbo-Croatian; (1900), 24,751. It is the seat of a Catholic and a Greek bishop, is a steamship station, has trade with Turkey, and considerable quantities of wine, oil, corn, and honey are produced in the neighbourhood, a further important resource of the inhabitants being fishing and seafaring.

Sedalia, a city of Missouri, U.S.A., capital of Pettis county. It is situated in 38° 43′ N. and 93° 14′ W., a little north and west of the centre of the state, at an altitude of 982 feet. It has an elevated prairie site. Three railways intersect here, the Missouri, Kansas and Texas, the Missouri Pacific, and the Sedalia, Warsaw and South-Western, making it a centre of importance. Locomotive and car works are situated here, besides which the city has manufactures of flour, wool, iron and steel, and agricultural implements. Population (1890), 14,068; (1900), 15,231, of whom 972 were foreign-born and 1725 negroes.

Sedan, chief town of arrondissement, department of Ardennes, France, 12 miles east-south-east of Mézieres on the railway from Mézieres to Nancy. There is a municipal school of weaving, but the value of the textile production has declined, being estimated in 1898 at only 25,000,000 francs. Population (1891), 17,023; (1901), 19,349.

Sedgley, a parish and urban district, Staffordshire, England, 3 miles south and included in the parliamentary borough of Wolverhampton, 1½ miles from Deepfields Station. Part of the parish is under an urban district council, the remainder being in the urban district of Coseley. The district abounds in coal, lime, and ironstone. Nails, rivets, chains, fire-irons, locks, and safes are made here. Population (1891), 14,961; (1901), 15,951.

Seeley, Sir John Robert (1834–1895), English essayist and historian, was born in London in 1834. His father, R. B. Seeley, was a publisher and author of several religious books and of *The Life and Times of Edward I.*, which was highly esteemed by historians. From his father Seeley doubtless derived his taste for religious and historical subjects. He was educated at the City of London School and at Christ's College, Cambridge, where he was head of the classical tripos and senior chancellor's medallist, was elected fellow and became classical tutor of his college. For a time he was a master at his old school, and in 1863 was appointed professor of Latin at University College, London. His essay *Ecce Homo*, published anonymously in 1866, and afterwards owned by him, was widely read, and called forth many replies, being held to be an attack on Christianity. Dealing only with Christ's humanity, it dwells on His work as the founder and king of a theocratic state, and points out the effect which this society, His church, has had upon the standard and active practice of morality among men. Some who condemned the book seem to have forgotten that it was avowedly "a fragment," and that the author does not deny the truth of doctrines which he does not discuss. Its literary merit is unquestionable; it is written with vigour and dignity; its short and pointed sentences are never jerky, and there is a certain stateliness in the admirable order of their sequence. His later essay on *Natural Religion*, which, premising that supernaturalism is not essential to religion, maintains that the negations of science tend to purify rather than destroy Christianity, satisfied neither the Christian nor the scientist, and though well written excited far less interest than his earlier work. In 1869 he was appointed professor of modern history at Cambridge. His influence as a teacher was stimulating; he prepared his lectures carefully and they were largely attended. In historical work he is distinguished as a thinker rather than a scholar. Avoiding research and disliking all attempts at a picturesque representation of the past, he valued history solely in its relation to politics, as the science of the State. He maintained that it should be studied scientifically and for a practical purpose, that its function was the solution of existing political questions. Hence he naturally devoted himself mainly to recent history, and specially to the relations between England and other States. His *Life and Times of Stein*, a valuable narrative of the anti-Napoleonic revolt, led by Prussia mainly at Stein's instigation, was written under German influence, and shows little of the style of his short essays. Its length, its colourlessness, and the space it devotes to subsidiary matters render it unattractive. Far otherwise is it with his *Expansion of England*. Written in his best manner, this essay answers to his theory that history should be used for a practical purpose; it points out how and why Great Britain gained her colonies and India, the character of her empire, and the

"PLOUGHING IN THE ENGADINE." By GIOVANNI SEGANTINI.

(By permission of T. Fisher Unwin, London.)

light in which it should be regarded. As a historical essay the book is a fine composition, and as a defence of the empire is unanswerable and inspiring. It appeared at an opportune time, and did much to make Englishmen regard the colonies, not as mere appendages, but as an expansion of the British state as well as of British nationality, and to remind them of the value of Great Britain's empire in the East. Seeley was rewarded for this public service by being made K.C.M.G., on the recommendation of Lord Rosebery. His last book, *The Growth of British Policy*, written as an essay and intended to be an introduction to a full account of the expansion of Great Britain, was published posthumously. Seeley died on 13th January 1895. He married in 1869 Miss Mary Agnes Phillott, who survived him.

See G. W. Prothero. *Memoir* prefixed to *Growth of British Policy.* London, 1895. (W. Hu.)

Segantini, Giovanni (1858–1899), Italian painter, was born at Arco in the Trentino on 15th June 1858. His mother, who died in 1863, belonged to an old family of the mountain country. His father, who was a man of the people, went to Milan, whence he set forth with another son to seek his fortune, leaving Giovanni behind. At the age of seven the child ran away; he was found perishing of cold and hunger, and was obliged to earn his bread by keeping the flocks on the hills. He spent his long hours of solitude in drawing everything he saw. Owing to the fame of the boy-prodigy having reached the ears of a syndic, the child was sent back to Milan; but, unable to endure domestic life, he soon escaped again, and led a wandering life till he met at Arco with his half-brother, who offered him the place of cashier in his provision shop. After more flights and more returns, Segantini remained at Milan to attend classes at the Brera, earning a living meanwhile by giving lessons and painting portraits. His first picture, "The Choir of Sant Antonio," was noticed for its powerful quality. After painting this, however, he shook himself free by degrees of academical teaching, as in his picture "The Ship." He subsequently painted "The Falconer" and "The Dead Hero," and then, thirsting once more for liberty, settled in Brianza, near Como. There he gave himself up to the study of mountain life, and became in truth the painter of the Alps. At this time he painted the "Ave Maria," which took a gold medal at the Amsterdam Exhibition (1883), "Mothers," "After a Storm in the Alps," "A Kiss," and "Moonlight Effect." Deeply impressed by Millet, whose influence may be traced in some of Segantini's drawings, the artist nevertheless quickly strove to reassert his individuality, as may be seen in "The Drinking-place," which gained a gold medal in Paris (1889), "In the Sheep-fold," "By the Spinning-wheel," and "Ploughing in the Engadine" (see Plate), for which he was awarded a gold medal at the Turin Exhibition (1892). Besides those works in which he studied simple effects of light and Alpine scenery, such as "Mid-day on the Alps" and "Winter at Savognino," he also painted symbolical subjects: "The Punishment of Luxury," and the "Unnatural Mothers" (in the Walker Art Gallery, Liverpool). Segantini died at Maloja in October 1899. An exhibition of his works was held in London, and afterwards at Brussels in 1899, and at Milan in 1900. Seven important pictures and nine drawings by Segantini were exhibited with success at the Paris Exhibition in 1900.

Segovia, a province of Spain, in Old Castile. Area, 2670 square miles. Population (1887), 154,443; (1897), 156,086. The birth-rate is 4·16 per cent., the death-rate 3·41 per cent., and the proportion of illegitimate births 1·80. Few of the inhabitants emigrate. Segovia is connected with Madrid and Medina del Campo by rail. This railway has not, however, stopped much of the traffic that still goes on through the passes of Nava Cerrada and Somosiera. Another line is in construction between Aranda de Duero and Segovia. The province is divided into 5 districts and 275 parishes.

The industries of Segovia have much decayed, especially porcelain and woollen stuffs. There are manufactures of coarse porcelain, dyes, chalk, paper, alcohol, rosin, hats, pins and needles, beer, flour, oil. It is estimated that more than 256,000 acres are covered with forests. In 1897 wheat was grown on 121,550 acres, rye, oats, barley, maize on 77,805 acres, pod fruit on 37,742 acres, and vines on 23,595 acres. In the same year the live stock in Segovia included 4714 horses, 12,645 mules, 18,062 asses, 26,687 cattle, 345,302 sheep, 14,063 goats, and 13,119 pigs.

Segovia, capital of the above province, on the railway from Villalba to Medina del Campo, near the river Eresma. It is still a walled city, and all its fine monuments of the Roman occupation as well as its mediæval buildings are kept in good state of preservation. Outside the older parts of the city modern suburbs have sprung up on all sides. The woollen industry has decayed, and its place has been taken by paper and flour mills, dyeing, foundries, earthenware, and some coarse porcelain. Segovia has a botanical garden, a savings bank, two public libraries, and two remarkable archive depots. Public education is well taken care of in the institute, a dozen primary schools, normal school for teachers, and arts and handicraft schools. Segovia has been for more than a century the royal artillery school of Spain. Population (1877), 11,318; (1897), 14,738.

Sehore, a town of Central India, with British cantonment, within the native state of Bhopal, situated in 23° 11′ N. and 77° 7′ E., with a station on the Bhopal–Ujain railway, 24 miles west of Bhopal. It is the residence of the political agent for the Bhopal agency, and headquarters of the Bhopal battalion. Population (1881), 15,595; (1891), 16,232. The number of police is 53 men. There are a high school, dispensary, and jail.

Seidl, Anton (1850–1898), Hungarian operatic conductor, was born at Budapest, 7th May 1850. He entered the Leipzig Conservatorium in October 1870, and remained there until 1872, when he was summoned to Bayreuth as one of Wagner's copyists. There he helped to make the first fair copy of *Der Ring des Nibelungen*. Thoroughly imbued with the Wagnerian spirit, it was natural that he should assist in the first Bayreuth Festival in 1876. His chance as a conductor came when, on Wagner's recommendation, he was appointed to the Leipzig Stadt-Theater, where he remained until, in 1882, he went on tour with Angelo Neumann's *Nibelungen Ring* company. To his conducting critics attributed much of such artistic success as attended the production of the Trilogy at Her Majesty's Theatre in June of that year. In 1883 Seidl went with Neumann to Bremen, but two years later was appointed successor to Leopold Damrosch as conductor of the German Opera in New York, and in the same year he married Fraulein Kraus, the distinguished singer. In America Seidl's orchestra became famous. In 1886 he was one of the conductors at Bayreuth, and in 1897 he filled a similar position at Covent Garden, London. He died in New York, 28th March 1898. Seidl was essentially a "modern" conductor of very considerable ability. (R. H. L.)

Seine, a river of France, rising in the Côte d'Or, and flowing generally north-west and west to the English Channel, at Havre. At Chatillon (Côte d'Or), 38 miles from its source, it has an altitude of only 705 feet, more than half its total descent having been accomplished. Its breadth on entering Paris is about 182 yards, and, on leaving, 149 yards. At Clichy, 1 mile north of the fortifications, the great sewer, into which practically the whole drainage system of Paris is directed, is discharged into the Seine. The tide begins to make itself felt at Poses, 11 miles above Elbeuf, and between Caudebec and Villequier the *mascaret*, or bore, has its greatest development. In 1878 it was decided, in order to facilitate the navigation of the river below Paris, that between the capital and Rouen several additional locks should be constructed and other improvements effected, so as to divide this part of its course into ten easy stretches. The work was completed in 1886. The head of the estuary is now found near Quillebeuf, and four miles lower down, between the lighthouses of Tancarville on the north-north-east, and Pointe de la Roque on the south-south-west, the width is 3½ miles. A canal 14 miles in length is carried across the alluvial plains north of the bay, between Tancarville and Havre. (See River Engineering.)

The Seine is classed as navigable from Méry to the sea, a length of 337 miles, and divided into nine sections. The navigation statistics here given are those for 1900. The total tonnage includes wood floated.

1. Méry to Marcilly, 16 miles. In this section navigation is purely nominal.
2. Marcilly to Montereau, 46 miles, mean depth 5·25 feet, crossed by 35 bridges; number of boats, 998 (of which 661 in descent); total tonnage, 103,355.
3. Montereau to the limits of the departments Seine-et-Marne and Seine-et-Oise, 36 miles, mean depth 5·5 feet, 35 bridges; 11,307 boats (6935 in descent); total tonnage, 1,945,287.
4. From preceding limits to Paris fortifications, 25 miles, mean depth 6·5 feet, 20 bridges; number of boats, 29,316 (16,685 in descent); total tonnage, 6,496,304.
5. Across Paris, 7½ miles, mean depth 10·5 feet, crossed by 37 bridges; number of boats, 32,633 (17,872 in descent); total tonnage, 7,494,037.
6. Paris fortifications to Briche, 13 miles, mean depth 10·5 feet, crossed by 13 bridges; number of boats, 16,461 (6357 in descent); total tonnage, 4,308,548.
7. Briche to confluence of Oise, 26 miles, mean depth 10·5 feet, 15 bridges; number of boats, 19,382 (4723 in descent); total tonnage, 4,966,029.
8. Confluence of Oise to Rouen, 106 miles, mean depth 10·5 feet, bridges 23; number of boats, 8634 (3184 in descent); total tonnage, 2,054,284.
9. Rouen to Havre, 78 miles, mean depth 22 feet; number of boats, 1808 (772 in descent); total tonnage, 328,614.

(E. J. H.)

Seine, a department of France, having Paris for its capital, watered by the Seine and the Marne, which unite at Charenton.

Area, 185 square miles. The population, 2,799,329 in 1881, had increased in 1901 to 3,599,870, of whom 939,311 were settled outside of Paris. The births in 1899 were 77,010, of which 19,054 were illegitimate; deaths, 73,219; marriages, 32,105. There were in 1896, 1807 schools, with 351,000 pupils, not more than 1 per cent. of the population being illiterate. The area cultivated was in 1896 estimated at 66,339 acres, of which 43,485 were arable and 1198 under vines. The wheat grown in 1899 was valued at £104,000; rye, £8000; oats, £43,000; potatoes, £92,000; vines, £29,000. The live stock in 1899 comprised 17,000 horses, 13,000 cattle, 1600 sheep, 2700 pigs, and 411 goats. There is no coal nor other minerals, except quarries of stone and plaster of Paris. There is, however, an active industry in metals, yielding in 1898, 34,000 metric tons of iron, 2300 tons of steel, and several tons of other metals, giving a total value of £282,000. Excluding those of the capital, the important industries are spinning, leather-dressing, chemical products, paper, &c. The chief places outside of Paris are St Denis, Boulogne, Puteaux, Choisy, Ivry, Montreuil, Vincennes, Suresnes, and Sceaux.

Seine-et-Marne, a department of northern France, watered by the Seine and the Marne.

Area, 2273 square miles. The population, 348,991 in 1881, had grown in 1901 to 355,638. The births in 1899 were 7226, of which 441 were illegitimate; deaths, 7815; marriages, 2679. With 927 primary schools (1896), attended by 52,000 pupils, there was but 1 per cent. of the population illiterate. The land under cultivation in 1896 comprised 1,388,140 acres, of which 992,940 acres were plough-land and 11,115 acres under vines. The harvest of 1899 yielded in wheat the value of £1,801,000; rye, £91,800; barley, £43,200; oats, £1,593,000; potatoes, £160,000; mangold-wurzel, £132,000; green crop (trefoil, lucerne, and sainfoin), £585,000; vines, £61,000. The live stock of 1899 included 43,960 horses, 92,050 cattle, 439,800 sheep, and 14,200 pigs. The milk produced in 1899 was valued at £1,193,300. With the exception of clay and building stone, Seine-et-Marne produced in 1898, in the way of minerals, only 80 metric tons of peat, and the industry in metals was represented by only 87 tons of iron, valued at £607. The distilleries, on the other hand, produced 1,541,000 gallons of alcohol, while the production of sugar exceeded 913,000 cwt. Melun, the capital, had in 1901, 10,820 inhabitants.

Seine-et-Oise, a department of northern France, watered by the two rivers naming it.

Area, 2185 square miles. The population, 577,798 in 1881, had increased to 700,405 in 1901. The births in 1899 were 14,427, of which 1164 were illegitimate; deaths, 15,849; marriages, 5234. There were in 1896, 1419 schools, with 95,000 pupils, 2 per cent. of the population being illiterate. Out of 1,286,870 acres under cultivation in 1896, 886,730 acres were plough-land, 41,990 acres garden land, and 14,820 acres vineyards. This department has a larger area laid out in gardens than any other department of France. The wheat grown in 1899 was valued at £1,204,400; rye, £93,000; barley, £49,000; oats, £853,000; potatoes, £47,000; natural pastures, £91,200; vines, £104,000; beetroot, £122,000. The live stock included (1899) 48,690 horses, 3312 asses, 95,700 cattle, 311,200 sheep, and 20,500 pigs. In the way of minerals this department yielded, in 1896, only 260 metric tons of peat. Nor is there any important industry in metals, only 3700 tons of iron having been manufactured in 1898. Only the industries connected with agriculture are on a scale of importance. The distilleries manufactured in 1898, 2,854,000 gallons of alcohol, and the sugar output amounted to 338,000 cwt. Versailles, the capital, numbered in 1901, 44,563 inhabitants.

Seine-Inférieure, a department of the north of France, washed by the English Channel and watered by the Seine.

Area, 2448 square miles. The population, 814,068 in 1881, had increased to 843,928 in 1901. The births in 1899 were 23,588, of which 3017 were illegitimate; deaths, 23,481; marriages, 6738. There were in 1896, 1479 schools, with 126,000 pupils, 7 per cent. of the population being illiterate. The land under cultivation in 1896 comprised 1,416,545 acres, of which 837,330 acres were plough-land, 14,820 acres in gardens, 148,200 acres in woods, and about 414,960 acres in natural pastures and grass lands, the vine not being cultivated in this department. One of the richest agricultural departments of France, Seine-Inférieure produced in 1899 wheat valued at £1,204,000; rye, £73,000; barley, £40,000; oats, £800,000; potatoes, £88,100; mangold-wurzel, £92,000; colza, £191,000; beetroot, £53,000; apples, £410,000. The live stock of 1899 included 71,650 horses, 279,010 cattle, 172,800 sheep, and 70,500 pigs. The milk produce of 1899 was valued at £1,402,000. The mining of the department yielded in 1898 only 350 metric tons of peat, silica, and ashlar. The metallurgic production of the copper foundries of Rouen, however, exceeded £190,000. The principal industry is that of cotton carried on in Rouen, Darnétal, Sotteville, Le Havre, and Yvetot, which maintains 1,600,000 spindles and more than 16,000 looms. The woollen industry is also very active in Elbeuf and its environs. The distilleries produced (1898) 1,437,000 gallons of alcohol. A good deal is done in the refining of sugar and the manufacture of glass and paper. The chief towns are Rouen, the capital, with 110,717 inhabitants; Le Havre, the second port of France, with 127,639, the special commerce of which in 1899 was valued at £54,400,000, and its general commerce at £68,300,000; Elbeuf, with 18,164 inhabitants.

Selborne, Roundell Palmer, Earl of (1812–1895), English lawyer and statesman, was born at Mixbury, in the county of Oxford, on 27th November 1812. His father was rector of the parish: his grandfather and great-grandfather were merchants in the City of London, where their descendants for a long while continued to be influential people; his mother belonged to the family of Roundell, which had been settled for four centuries in the West Riding of Yorkshire. He was educated at Rugby and at Winchester, and in 1830 went into residence in the University of Oxford as a scholar of Trinity College. Here he lived in intimacy with many friends, especially Claughton and Charles Wordsworth. He soon joined the Union Debating Society, of which Gladstone was at that time president; and there Palmer first tried his powers in debate. In 1834 he took his degree in the first class of the school of *Literæ Humaniores;* he won the Eldon scholarship and was elected to a fellowship at Magdalen College; and after a year, spent chiefly in private tuition, partly in Lord Winchilsea's house and partly in the University, he removed to London (November 1835) and commenced reading for the Bar. In London he found himself surrounded by members of his own family, and through their influential position, as well as through his own and his father's friends, he obtained a freer access to much good society than is usually the lot of a young man coming to London from a university. Meanwhile events had happened which were felt by Palmer, when he looked back in after life, to have been turning points in his mental history. In 1832 his mother had been affected by a very distressing illness, which continued for years, and in the winter of 1834–35 his brother Henry was lost at sea.

Palmer was called to the Bar on 7th June 1837, the same day on which John Rolt, a man of very different antecedents, but afterwards a worthy rival of Palmer, was also called. Through his family connexions in the City of London, clients soon came to Palmer's chambers, and his business at the Chancery bar increased rapidly. Meanwhile his interests were not wholly confined to law: for some time (1840–43) he wrote for *The Times* and the *British Critic;* he made a plunge into patristic learning, from which he soon recoiled; he was much interested in the controversies which distracted the Church on the subject of Tract 90; in the treatment of the Episcopal Church in Canada by the Canadian Government and the Colonial Office; in the establishment by the Crown, in conjunction with the king of Prussia, of the Jerusalem bishopric; and in the contest for the professorship of poetry at Oxford on Mr Keble's retirement.

In 1847, and again in 1853, Palmer was returned as member of Parliament for Plymouth, as a Peelite, and in the House of Commons he took an active and independent part. He advocated the admission of Jews to Parliament; he opposed Lord John Russell's measure to repel the so-called papal aggression; he opposed the admission of Dissenters into the University of Oxford; and he was hostile to the action of the Government in the Crimean war. On the question of the reform of the University of Oxford, he sympathized with the reformers, but felt himself prohibited, by the oaths which he had taken, from assuming any active part in the promotion of change. In 1855 he supported Gladstone in the efforts to bring about peace with Russia before the capture of Sebastopol; in 1856 he opposed the opening of museums on Sunday; in the following year he supported Cobden in his disapproval of the second opium war with China. At the general election on March 1857, Palmer, finding that the independent part he had taken, especially in reference to the Chinese question, had alienated from him many of his constituents in Plymouth, abandoned the prospect of re-election for that borough, and did not seek for election elsewhere. In 1848 he married Lady Laura Waldegrave, daughter of Earl Waldegrave. In 1849 he had become a Q.C.; and in 1851 he took his seat in the Rolls Court, where he soon obtained a leading and very lucrative practice, and was engaged in many of the most important cases in the Court of Chancery. In July 1861 he accepted from Lord Palmerston the office of solicitor-general, a knighthood, and a safe seat for the borough of Richmond in Yorkshire, secured for him through the friendly action of Lord Zetland, and thus began the second spell of Palmer's membership of the House of Commons, which continued till his elevation to the woolsack and the peerage. In September 1863 he become attorney-general, and so continued till the Government of which he was a member resigned in 1866.

The Civil War in America, and the questions which arose from the relations of Great Britain with both belligerents, rendered the duties of the law officers of the Crown more than usually onerous, and Palmer was called upon to take part, as adviser of the ministry, in the Courts, and in the House, in the questions which arose in respect of the *Trent* and the *Peterhoff*, the cruisers *Alabama* and *Florida*, and the *Alexandra*, a ship which was seized by the Government, and other matters. In 1865 he took a large part in the passing of the Act under which all the law courts were gathered together in the Strand. In 1866 he expressed himself favourable to the making of household suffrage the basis of representation, an expression of opinion which probably influenced the Reform Bill of the following year—in the discussions on which Palmer took a prominent part, and especially in opposition to the so-called "fancy franchises" originally proposed by its authors. In the same year he took part in supporting the measure for the abolition of compulsory Church rates.

In 1868 occurred an event of great importance in his career. In April of that year Gladstone proposed his resolutions with reference to the Irish Church on which the Bill for its disestablishment was subsequently based. This measure was opposed to many of the dearest beliefs and feelings of Palmer, who was a strong and conscientious Churchman, and he evidenced his disapproval of his chief's measure by abstaining from voting on the resolutions. At the election of November 1868 Palmer was again returned for Richmond, and Gladstone offered him the office of lord chancellor or the office of a lord justice with a peerage; both offers were declined by Palmer, and he assumed a position of independent opposition to the measure relative to the Irish Church. On the 22nd March 1869 he delivered a very powerful speech against the second reading of the Bill, and during its later stages exercised a considerable influence in modifying the severity of its provisions. The position of Palmer at this time was very remarkable. The foremost advocate at the Bar, he was known to have declined the highest prize in the profession rather than promote a measure of which he disapproved; a very prominent member of the House of Commons, whose action had been more than usually independent of party, he had separated himself from his political friends and maintained a position as the dignified and forcible opponent of Disestablishment. Without office and without combination with the Conservative Opposition, he exercised great influence within and without the walls of St Stephen's. What made his position the more remarkable was that he was frequently consulted by the Government which he had declined to join, and that on some occasions

they invoked the assistance which his great influence in the House enabled him to afford to them.

In 1869 he sought to modify rather than to oppose the Bill for the abolition of tests in the universities. In 1870 he gave a qualified support to Gladstone's first Irish Land Act, and in the same year he supported Forster's Education Act. In 1872 he undertook the defence of his friend Lord Chancellor Hatherley, when attacked for his appointment of Sir Robert Collier to the Judicial Committee of the Privy Council, and, by a line of argument more ingenious than convincing, secured a majority for the Government.

The Treaty of Washington was the means of casting a great duty upon Palmer. After the conclusion of the Civil War in America very large claims were preferred against Great Britain for alleged breaches of her duty as a neutral Power; and after long negotiations, England and the United States agreed to arbitration. Palmer, who had been advising the British Government during these negotiations, and who (4th August 1871) had defended the treaty in the House of Commons, was briefed on behalf of Great Britain. In the end the Geneva tribunal made an award requiring the payment by Great Britain to the United States of a sum of about £3,000,000. To those who, in order to promote the cause of international arbitration, are desirous of acquiring a knowledge of the dangers and difficulties which beset this mode of settling disputes, the account which Palmer has left of his part in this arbitration may be commended.

In September 1872 Gladstone again offered him the Great Seal, which Lord Hatherley had resigned; and he also for the first time took up his residence in his newly erected house at Blackmoor, in the parish of Selborne, in the county of Hampshire, from which he took his new title as a peer. In the following year (1873) Lord Selborne carried through Parliament the Judicature Act. The foundations of this measure were laid so long ago as February 1867, when Palmer had moved for a Royal Commission on the constitution of the courts, and had taken an active part in the work of that Commission, of which the first report was made in 1869. The result of this Act of 1873 was to effect a fundamental change in the judicature system. By the operation of the Judicature Act one supreme court with several divisions was constituted; each division could administer the whole law; the conflict of divergent systems of law was largely overcome by declaring that when they were at variance, the principles of equity should prevail over the doctrines of the common law. The details of this great change were embodied in a code of general rules prepared by a committee of judges, over which Lord Selborne for two years presided week by week, with unfaltering attention to the minutest detail. If, wrote Lord Selborne in his memoirs, speaking of the Judicature Act of 1873, "I leave any monument behind me which will bear the test of time, it may be this." It is impossible to separate this fusion of law and equity, this union of all the higher courts into one supreme tribunal, from the construction of a single home for this great institution; and the opening of the Royal Courts in the Strand in the year 1882, when Queen Victoria personally presided in her one supreme court, and handed over the care of the building to Lord Selborne, as her chancellor and as the head of this great body, was impressive as an outward and visible sign of the silent revolution, which owed more to Lord Selborne than to any other individual. To the student of the natural history of jurisprudence the fusion of the two systems of law and equity may well recall a similar result brought about in Imperial Rome; to the student of British institutions, the supreme court, for once presided over in person by the sovereign, could not but recall the Aula Regia, where the Norman kings sat amid their counsellors before equity had arisen to correct law, and before the separation between the three great common law courts had begun. A small incident may illustrate the novelty of the assemblage of the one great court on that day. The Queen, on the prayer of the attorney-general, ordered that the proceedings of the day should be recorded, an order which caused a momentary embarrassment to the lord chancellor, as the court had no existing registrar, and no existing book in which the record should be made. On the occasion of the opening of the Royal Courts Lord Selborne received an earldom.

The year 1885 was marked in Lord Selborne's life by the death of his wife, and by his final separation from the party of which Gladstone was the acknowledged leader. That statesman had in the latter part of the year indicated his leaning towards the disestablishment of the Church of England, and towards Home Rule for Ireland. Both these leanings were opposed to the deepest convictions of Lord Selborne; and it was an inevitable result that when in January 1886 Gladstone resumed office as premier, Lord Selborne should not be again his chancellor: on the 30th January in that year they parted for ever; and Lord Selborne felt that his public life, except so far as he might serve his country by voice or pen, was now over, and that his "idols were broken." But neither his courage nor his industry forsook him; and he found, in opposing the new views of his old colleague, ample scope for both voice and pen; and as a member of the House of Lords he continued almost to the last to take part in hearing and deciding appeals, and sometimes in the ordinary business of the House.

In addressing the electors of Midlothian in September 1885, Gladstone had suggested the severance of the Church of England from the State as a subject on which the foundation of discussion had already been laid, and he averred the existence of "a current almost throughout the civilized world, slowly setting in the direction of disestablishment." Such an utterance from such a man greatly excited the hopes of Nonconformists, who had previously published a manifesto under the title of "The Case for Disestablisment." This stirring of the question deeply moved Lord Selborne, who was strongly opposed alike to disestablishment and disendowment, and in the following year, 1886, he published a work entitled *A Defence of the Church of England against Disestablishment*, with an introductory letter addressed to Gladstone. In the introductory letter he criticized Gladstone's pronouncement on the subject, and especially examined the allegation of a general tendency towards disestablishment in the civilized world at large, and arrived at a negative conclusion. In the body of the book the learned author treated of the history of the English Church, its endowments, and the case of the advocates of disestablishment. The work is throughout characterized by an abundant supply of learning and of information as to the history and the state of the Church of England at that time, and by great dialectical acuteness. It is a powerful defence as well as a valuable summary of the history of the Established Church in England. In 1888 Lord Selborne published a second work on the Church question, entitled *Ancient Facts and Fallacies concerning Churches and Tithes*, in which he examined more critically than in his earlier book the developments of early ecclesiastical institutions, both on the Continent and in Anglo-Saxon England, which resulted in the formation of the modern parochial system and its general endowment with tithes. A second edition of this

work, embodying the result of its author's subsequent researches in the Vatican Library and elsewhere, was published in the year 1892. A perusal of these books will show with how wide a range of investigation and with what care Lord Selborne prepared himself for the discussion of these ecclesiastical questions which deeply stirred him. But Lord Selborne did not carry on his opposition to Gladstone's proposals only in his library or by his pen; in the year 1886–87 he travelled to many parts of the country, and addressed influential public meetings in defence of the union between the Church and State and against Home Rule; and in September 1893, in his eighty-first year, he addressed a powerful speech to the House of Lords in opposition to the Home Rule Bill.

Lord Selborne's health had, with the exception of two collapses in 1883 and 1888, which appear to have been due to overwork, continued excellent till February 1895, when he was attacked by influenza. He died 4th May 1895 at his seat in Hampshire, full of years and honours.

To the subject of university education Lord Selborne at different times in his life gave much time and attention. As a fellow of Magdalen College, he had been desirous of changes which he felt himself bound by his oath from advocating; and he had taken part in the discussions on the abolition of tests in the old universities.[1] He gave much time and attention to his duties as chairman of the second Oxford commission under the Act of 1876; in 1878 he filled the office of lord rector of the university of St Andrews; and in the following year he presided over a commission on the subject of university education in London. Lord Selborne's literary labours included the publication in 1862 of a selection of hymns, under the title of *The Book of Praise*, a work in which he was greatly assisted by Mr Daniel Sedgwick, a bookseller and publisher in the City of London. The work was characterized by the great pains taken to ascertain the true authorship of hymns which were either anonymous or attributed to those who had not composed them, and by a like effort to exclude all variations grafted on the original language, and to give the hymns "in the genuine uncorrupted text of the authors themselves." In the course of his labours as editor of this volume he was struck by the unity which was presented by Christian hymnody, "binding together by the force of a common attraction, more powerful than all causes of difference, times ancient and modern, nations of various race and language, Churchmen and Nonconformists, Churches reformed and unreformed" (Preface). In the same field of literature Lord Selborne further laboured by the publication of another collection called *The Book of Praise Hymnal*; a contribution to an edition of Bishop Ken's hymns; a paper on English Church Hymnody at a Church Congress; an article in the *Encyclopædia Britannica* on the hymns of the Latin and Oriental Churches, as well as those of Germany and Great Britain, which was republished as a separate volume in 1892.

During the last few years of his life Lord Selborne engaged in the composition, for the benefit of his children, of memorials of his own life and of the lives of many members of his family. These *Memorials, Part I., Family and Personal*, in 2 vols., which were published in 1896, *Memorials, Part II., Personal and Political*, also in 2 vols., were edited by Lady Sophia Palmer and published in 1898. In the years 1880–81 Lord Selborne wrote to his son a series of letters on religious subjects, dealing in an elementary way with natural and revealed religion, the inspiration of the Bible, and Biblical criticism. These were published in 1898, under the title of *Letters to His Son on Religion, by Roundell, First Earl of Selborne.*

In person Lord Selborne was of about the average height: his manners when among strangers were somewhat reserved; his style, both in speaking and writing, was fluent, tending to diffuseness; his oratory was marked by uniform good sense and lucidity, both of arrangement and language; and if he never reached the highest level of oratorical excellence, he never descended to what was commonplace or irrelevant. As a judge, whether in the Supreme Court or in the House of Lords, he displayed high qualities: he was patient, courteous, logical, and learned, and his judgments contain many valuable expositions of the principles of law. The fusion of law and equity, the reorganization of the whole judicial system of England, and the association of all the supreme tribunals in one common home were works of no ordinary magnitude or importance, and give a character of unusual importance to his chancellorship.

That Lord Selborne was a truly religious man it is impossible to doubt: his whole life was regulated and inspired by a sense of his duty towards God and his fellowmen, and a long life spent amid the temptations of legal and public life left not the faintest stain on his memory. He was a devout member of the Church of England, to which he looked up with unstinted affection and reverence; and he found in its service and formularies an adequate satisfaction for all his religious feelings. He belonged to the High Church school, which was influenced by the teaching of Newman and Pusey and the Oxford teachers of their day; but he by no means slavishly followed them. With the later High Church movement, usually described as Ritualism, he had less sympathy.

His life was prosperous, for from his first prize at the university till his acquisition of an earldom, he went on a course of almost unbroken success. He had the double dignity of having refused the highest prize in his profession for conscience' sake, and of having accepted that dignity without loss of consistency; in his life he acquired a high reputation and the sincere admiration of his fellowmen, as well as an abundant fortune and ample titular distinctions. His life was also happy, for he had pleasure in his work, he loved and was loved by his wife and children; he had a strong constitution, and retained his bodily and mental powers to the last; his faith in the religion of his youth was unshaken to the end; and he lived throughout his long life with the consciousness of rectitude. (E. F.)

Selenghinsk, Old and New, two towns of East Siberia, in the province of Transbaikalia, on opposite banks of the Selenga. The latter, on the left bank, is a district town, but both are small; formerly important centres of trade with China, they lost their importance with the growth of Kiakhta. A colony of English missionaries is close by. It was here that the Treaty of 1688 was concluded by Russia with the Mongol princes, who swore allegiance to their northern neighbour. The population of the district town in 1897 was 1076.

Selkirk, a royal and parliamentary burgh (Border group) and the county town of Selkirkshire, Scotland, on the river Ettrick, 37 miles south-south-east of Edinburgh by rail. There are fourteen woollen factories; also, engineering and millwright works. Modern erections include a United Free church, a public hall, and a free library. Population (1891), 6397; (1901), 5701.

---

[1] In 1867 he founded an association for the improvement of legal education, in the hope of bringing about the establishment or the restoration of "a general school of law in London on a scale worthy of the importance of the law and of the resources of the Inns of Court." This enterprise was not successful. The opposing forces were too strong to permit Lord Selborne to succeed.

Selkirk Mountains. See CANADA.

Selkirkshire, an inland lowland county of Scotland, bounded on the N. by Midlothian, on the N. and W. by Peebles, on the S. by Dumfries, and on the E. by Roxburgh.

Area and Population.—In 1891 Innerleithen and Peebles parishes were placed wholly in Peebles; Lyne and Megget was divided, and Lyne was restricted to Peebles, while Megget was added to the Selkirk parish of Yarrow. Part of Yarrow was given to the Peebles parish of Traquair. Selkirk, Ashkirk, and Galashiels were placed wholly in Selkirk, Roberton was placed wholly in Roxburgh, and part of Melrose was transferred to the Selkirk parish of Galashiels. The area of the county is 172,426 acres, or about 269 square miles. The population was, in 1881, 25,564; in 1891, 27,353; in 1891, on the above area, 27,712; in 1901, 23,371, of whom 10,680 were males and 12,691 females. On the old area, taking land only (164,545 acres, or 257·1 square miles), the number of persons to the square mile in 1901 was 90·8, and the number of acres to the person 7·4. In the registration county the population increased between 1881 and 1891 by 6·6 per cent. Between 1881 and 1891 the excess of births over deaths was 3833, and the increase of the resident population 1781. The following table gives particulars of births, deaths, and marriages in 1880, 1890, and 1899:—

Year.	Deaths.	Marriages.	Births.	Percentage of Illegitimates.
1880	450	163	927	8·6
1890	474	176	757	6·74
1899	365	160	473	5·3

The following table gives the birth-rate, death-rate, and marriage-rate per thousand of the population for a series of years:—

	1880.	1881-90.	1890.	1891-98.	1899.
Birth-rate . .	37·00	29·78	27·09	23·14	16·21
Death-rate . .	17·47	14·69	16·96	13·98	12·51
Marriage-rate .	6·33	5·45	6·30	5·49	5·47

In 1891 there were 78 Gaelic-speaking persons in the county, and 24 foreigners. Valuation in 1889–90, £63,061; 1899–00, £63,806.

Administration.—The county unites with Peebles to return a member to Parliament, and contains two burghs of the Border parliamentary group, Selkirk and Galashiels. Selkirk (5701), the county town, is the only royal burgh, and Galashiels (13,598) is the only other place above the rank of village. There are six civil parishes, and the number of paupers and dependents in September 1899 was 432. Selkirk forms a sheriffdom with Roxburgh and Berwick, and a resident sheriff-substitute sits at Selkirk and Galashiels.

Education.—Nine school boards manage 17 public schools, which had an average attendance of 3729 in 1898–99, and 5 voluntary schools (2 Roman Catholic and 1 Episcopal) had 533. There are high schools at Galashiels and Selkirk, and 3 other schools in the county earned grants in 1898 for giving higher education. Part of the "residue" grant is spent in supporting short courses of instruction in dairying, and Selkirk Town Council subsidizes popular science classes in the burgh school.

Agriculture.—Oats cover all but a few hundred acres of the corn land. The percentage of cultivated area in 1898 was 17·4. Of the 226 holdings in 1895 the average size was 134 acres. The percentage under 5 acres was 17·70, between 5 and 50 acres 38·50, and over 50 acres 43·80. The number of farms between 50 and 100 acres was 19; between 100 and 300, 42; between 300 and 500, 18; and over 500, 20. The following table gives the principal acreages at intervals of five years from 1885:—

Year.	Area under Crops.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1885	23,820	4656	3013	7598	8,045	14
1890	24,209	4495	2982	7420	9,291	9
1895	30,392	5279	3410	9545	12,065	28
1899	30,054	5239	3296	9116	12,391	...

The following table gives particulars of the live stock during the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or Calf.	Sheep.	Pigs.
1885	567	2748	1043	164,314	495
1890	609	3088	1109	163,724	469
1895	738	3418	1343	181,031	509
1899	714	3223	1323	184,957	373

The area under wood in 1895 was 4942 acres. At the census of 1891, 1084 men and 98 women were returned as being engaged in agriculture.

Industries and Trade.—Galashiels and Selkirk produce a large output of woollen yarn, tweeds and tartans, besides hosiery. Galashiels has also iron foundries, engineering works, and dye-works. There are large market vineries at Clovenfords. In 1891 the industrial population numbered 6004 men and 3600 women, of whom 3434 men and 3048 women were engaged in the manufacture of textiles.

Sella, Quintino (1827–1884), Italian statesman and financier, was born at Mosso, near Biella, on 7th July 1827. After studying at Turin and Paris, he was appointed to the chair of geometry at Turin University in 1852, and in 1860 was elected deputy. A year later he was selected to be secretary-general of public instruction, and in 1862 received from Rattázzi the portfolio of finance. The Rattazzi cabinet fell before Sella could efficaciously provide for the deficit of £17,500,000 with which he was confronted; but in 1864 he returned to the ministry of finance in the Lamarmora cabinet, and dealt energetically with the deficit of £8,000,000 then existing. Persuading the king to forego £120,000 of his civil list, and his colleagues in the cabinet to relinquish part of their ministerial stipends, he effected savings amounting to £2,400,000, proposed new taxation to the extent of £1,600,000, and induced landowners to pay one year's instalment of the land tax in advance. A vote of the Chamber compelled him to resign before his preparations for financial restoration were complete; but in 1869 he returned once more to the ministry of finance in a cabinet formed by himself, but of which he made over the premiership to Lanza. By means of the grist tax (which he had proposed in 1865, but which the Menabrea cabinet had passed in 1868), and by other fiscal expedients necessitated by the almost desperate condition of the national exchequer, he succeeded, before his fall from power in 1873, in placing Italian finance upon a sound footing, in spite of the fiercest attacks and persistent misrepresentation of his aims. In 1870 his great political influence turned the scale against the proposed alliance with France, and in favour of an immediate occupation of Rome. From 1873 until his premature death on 14th March 1884, he acted as leader of the Right, and was more than once prevented by an ephemeral coalition of personal opponents from returning to power as head of a Moderate Conservative cabinet. A man of the utmost integrity and moral courage, Sella combined with both an intelligence and an ability rare among Italian statesmen. As a scientist he was scarcely less eminent than as a politician. Since his death the amplest homage has been rendered to his merits by those who during his lifetime were most active in attempting to thwart his patriotic activity. (H. W. S.)

Sellar, William Young (1825–1890), Scottish classical scholar, was born at Morvich, Sutherlandshire, 22nd February 1825. Educated at the Edinburgh Academy and afterwards at the University, he passed to Balliol College, Oxford, of which he became a scholar. Graduating first class in classics, he was elected fellow of Oriel, and after holding assistant professorships at Durham and Glasgow, was appointed professor of Greek at St Andrews. After filling that office for six years, he was elected in 1863 to the professorship of humanity at

Edinburgh University, and occupied that chair down to his death at his residence, Kenbank, near Dalry, Galloway, on 12th October 1890. Sellar was one of the most brilliant of modern classical scholars, and was remarkably successful in his endeavours to reproduce the spirit rather than the letter of Roman literature. *The Roman Poets of the Republic* (1863), *The Roman Poets of the Augustan Age* (1877), and *Horace and the Elegiac Poets* (1892), are his most prominent works, and are recognized as standard authorities on the subjects with which they deal. Professor Sellar also contributed to the 9th edition of the *Encyclopædia Britannica* a series of brilliant articles on the Roman poets.

Selma, a city of Alabama, U.S.A., capital of Dallas county. It is situated in 32° 25′ N. and 87° W., on the right bank of the river Alabama, near the centre of the state, at an altitude of 126 feet. The river is navigable to this point, and this with the four railways centring here, the Birmingham, Selma, and New Orleans, the Louisville and Nashville, the Southern and the Western of Alabama, give Selma a large trade. This is principally in cotton, the chief crop of the surrounding country, and in lumber from the great pineries. The city contains railway shops and manufactures and large cotton warehouses. Population (1890), 7622, of which 3914, or more than one-half, were coloured; (1900), 8713, of whom 214 were foreign-born and 4429 negroes.

Selwyn, George Augustus (1809–1878), bishop of New Zealand, was born at Church Row, Hampstead, 5th April 1809, and was the second son of William Selwyn, a distinguished legal writer. He was educated at Eton. Proceeding to Cambridge, he became scholar and afterwards fellow of his college. He was also famous as an athlete, having rowed in the University boat. He took his degree (second in the classical tripos) in 1831. He then returned to Eton as private tutor, was ordained deacon in 1833, and devoted himself with characteristic energy to work in the parish of Windsor. His vigour, determination, and ability soon marked him out for preferment; but when it arrived, it was hardly in a form expected or altogether approved by his friends. In 1841 it was proposed that he should go out as first bishop to New Zealand, which was just beginning to be colonized. The well-known *mot* of Sydney Smith embodied the opinion of London society on the unpromising nature of the career thus offered him. Selwyn, nevertheless, accepted the offer without hesitation. He started at once for his diocese, studying Maori on the voyage out, and threw himself into his work with all his heart. He lived a life of continual strain and hardship. He was days and sometimes nights in the saddle. He swam broad rivers; and having provided himself with a sailing vessel, soon became as much an expert in navigation as the most experienced sailor in the colony. Unfortunately, when by his devoted labours he had gained the confidence of the natives, his ascendancy was rudely shaken by the first Maori war. Selwyn endeavoured to mediate; but the only apparent result for the time was that he incurred the hostility of both parties. He went to the battlefield to minister to the bodily and spiritual needs of the sick and wounded in both camps; but the Maoris were persuaded that he had gone out to fight against them, and years afterwards one of them pointed out a scar on his leg to an Anglican bishop, which he declared had been inflicted by Bishop Selwyn's own hands. Still, the bishop persevered, through evil report and good report, but he was long before he could regain the confidence he had forfeited by his strict adherence to the line of his duty. In 1854 he returned to England for a short period of rest and refreshment; but he spent much of it in pleading the needs of his diocese, and there are those still who remember the scene when, in impassioned tones, and with eagle eye glancing round the crowded church, he advocated the cause of missions in his Ramsden Sermon at St Mary's, Cambridge, and bid those present to "fill up the void" then existing, an appeal which drew Bishop Mackenzie to the mission field, and to a virtual martyrdom by the river Zambezi. Selwyn returned to New Zealand with a band of able associates, and henceforth set himself to divide the single diocese he had hitherto endeavoured to administer into sees of more manageable proportions. By degrees he met with the appreciation his lofty character and high sense of duty deserved. The colonists came to respect his uprightness, and the Maoris learned to regard him as their father. In 1868 Bishop Selwyn paid another visit to England to attend the first General Conference of Bishops of the Anglican Communion. While in England, the bishopric of Lichfield became vacant, and it was offered to him, and unhesitatingly declined. A difficulty, however, having arisen about filling up the see, it was once more offered to him, with the intimation that his appointment, and his only, would put an end to the deadlock which had occurred. He then considered that it was his duty to accept it. In his new sphere of work he displayed the same unselfish activity as before, and in the "Black Country" portion of his diocese he won the hearts of the working classes by his frank and hearty sympathy. He called his clergy and laity together for consultation in the diocesan conference, a part of the working of his colonial see of the value of which he had become convinced by experience. This was at first resisted as an innovation; but its usefulness was proved by the fact that a similar conference is now a feature in the working of every diocese in England and Wales. The health of the bishop soon began to suffer from the change from the freer life in the open air to which he had been accustomed. His splendid vitality slowly declined, and he died 11th April 1878.

The Anglican communion has reason to be grateful to him for the constitution for the Church under his care, which he elaborated in conjunction with Sir George Grey, the bishop and layman working in brotherly accord. This constitution has served as a model for the organization of many other non-established branches of the Anglican Church. (J. J. L*.)

Selwyn, John Richardson (1844–1898), bishop of the Melanesian Islands, the son of George Augustus Selwyn, first bishop of New Zealand and afterwards bishop of Lichfield, was born in New Zealand, 20th May 1844. He was educated at Eton and at Trinity College, Cambridge. He intended at first to follow the profession of the law; but fired by the example of the privations cheerfully endured by his father for the sake of the Church, he ultimately offered himself for holy orders. His ordination to the diaconate took place in 1869, after his father had accepted the bishopric of Lichfield. At first he laboured with energy and tact in his father's English diocese; but the news of the martyrdom of Bishop Patteson in Melanesia led him to volunteer for service in the Australasian Archipelago. After a period of three years, during which the bishopric remained vacant, he was nominated as Bishop Patteson's successor. This was in 1877. For twelve years he threw himself with intense energy into his most arduous work; and then his health entirely broke down, and he returned to England a hopeless cripple, but found a most appropriate sphere in the headship of Selwyn College, Cambridge, an institution founded in memory of his father's remarkable

work in New Zealand. He was appointed in 1893, and until his death, 12th February 1898, he employed such strength as remained to him in inspiring the undergraduates committed to his care with the spirit of unselfish heroism which had characterized his life. (J. J. L*.)

Semaphore, a town, South Australia, in the county of Adelaide, 9½ miles by rail from the town of Adelaide. It is one of the chief watering-places of the state, with a pier 1800 feet long. Its population is about 8000.

Semendria (Servian, *Smederevo*), an important commercial town in the kingdom of Servia, on the Danube, between Belgrade and the Danubian Cataracts. It is believed to stand on the site of the Roman settlement *Mons aureus*, and there is a tradition that its famous vineyards—supplying Budapest and Vienna with some of the finest table grapes—were planted by the Roman Emperor Probus in the 3rd century of the Christian era. At the eastern end of the town, close to the river, there is a picturesque triangular castle with 24 square towers, built by the Servian Prince Gyuragy Brankovich in 1430, on the model of the Constantinople walls of that time. Semendria was the residence of that Servian ruler and the capital of Servia from 1430 to 1459. It is the seat of the district prefecture and a tribunal, and has a garrison of regular troops. Besides the special export of grapes and white wine, a great part of the Servian export of pigs, and almost all the export of cereals, passes through Semendria. Since 1886 the town has been connected with the Belgrade-Nish Railway by a branch line. Population (1900), 6912.

Semenovka, or SEMIONOVKA, a town of Russia, in the government of Chernigov, 14 miles by rail from Gomel. Its industries comprise manufactures of leather, sheepskins, boots, pottery, and oil, and it is a centre for trade in bristles, and for pedlars; it also has several fairs of local importance. Population (1897), 15,125.

Semipalatinsk, a province of Russian Central Asia belonging to the General-Governorship of the Steppes, bounded on the N. and N.E. by Tomsk, on the S.E. and E. by the Chinese province of Chuguchak, on the S. by the Russian provinces Syr-Daria and Semiryechensk, and on the W. by Akmolinsk. Its area is 184,631 square miles, and in 1897 its domiciled population was 685,197 (688,639 according to other reports), of whom 320,358 were women, and 55,093 lived in towns. Only 6 per cent. of the population was settled, the remainder, chiefly Kirghiz, being nomads. 555,259 were Mussulmans and 65,718 belonged to the Russian Orthodox Church. The province is divided into 5 districts, the chief towns of which are: Semipalatinsk (26,353), Pavlodar (7730), Kokbekty (2908), Karkaralinsk (4455), and Ust Kamenogorsk (8958). The standard of education is low; in 1895 there were only 100 primary schools, attended by 3115 boys and 675 girls, and two gymnasia, one for boys (57), and one for girls (182). The Kirghiz have their own schools, which they are very eager to found, and for which they collect their own funds. Agriculture is the chief occupation of the Russians and of part of the Kirghiz. It is impossible to carry it on without irrigation; but it is nevertheless widely spread, and the average yield in the years 1895 to 1899 was: rye 72,800 cwt., wheat 1,237,800 cwt., oats 408,300 cwt., barley 41,400 cwt., millet 159,500 cwt., and potatoes about 100,000 cwt. Flax and hemp are also grown, and melons are cultivated in fields; tobacco is widely grown. Cattle-breeding is the chief pursuit of the Kirghiz, and there were in 1895, 549,840 horses, 291,400 horned cattle, 1,700,000 sheep, and 61,600 camels. Bee culture is widely spread, especially among the Cossacks, and more than 15,000 beehives were registered in 1895. Fishing, which is carried on on Lakes Zaisan, Balkhash, and others, as also on the Black Irtysh, is of considerable importance. Gold is extracted, to the amount of 464 kilogrammes per annum, by nearly 4500 workers; also silver (896 kilogrammes), copper (850 cwt.), salt (42,000 tons) from the salt lakes, and coal (1500 tons in 1897), which has only begun to be extracted. There are two iron-works, but industry remains in its infancy, and the only other industrial establishments of any size are a large steam flour-mill and a distillery; the annual aggregate return of all factories is only £33,000. A considerable amount of trade is carried on, however, within the province, in which twenty fairs are held every year. The trade with China is chiefly in cattle, hides, wool, and felt, imported; and cottons and other manufactured goods, exported.

Semipalatinsk, the capital of the above province, on the right bank of the Irtysh, and on the highway from Central Asia to Omsk, 481 miles south-east of that city. It carries on a considerable trade, especially with the Kirghiz, and has one flour-mill, one distillery, and several tanneries. It has also a library and museum, two gymnasia, for boys and girls, and schools for the Kirghiz. Steamers ply on the Irtysh to Omsk and Lake Zaisan. Population (1881), 17,820; (1897), 26,353.

Semiryechensk, a province of Russian Turkestan, bounded on the N. by Semipalatinsk, on the E. and S. by the Chinese provinces of Chuguchak, Kulja, Aksu, and Kashgar, and on the W. by the Russian provinces of Fergana, Syr-Daria, and Akmolinsk, with an area of 152,280 square miles. Its climate is thoroughly continental. In the Balkhash Steppes the winter is very cold; the lake freezes every year, and the thermometer falls to 13° F. In the Alakul Steppes the winds blow away the snow. The passage from winter to spring is very rapid, and the prairies are rapidly covered with vegetation, which, however, is soon dried up by the sun. The average temperatures are: at Vyernyi (2430 feet high), for the year 46° F., for January 17°, for July 74°; at Prjevalsk (altitude 5800 feet), for the year 44°, for January 23°, for July 63°; still higher in the mountains, at Naryn (altitude 6640 feet) the average temperatures are only, for the year 37°, for January 1°, for July 64°. The yearly rainfall at these three places is 21·6, 16·0, and 11·8 inches respectively. The population, which was estimated at 671,880 in 1891, in 1897 was found to be 990,107 (domiciled only), of whom 458,744 were women, and 59,659 lived in towns. Kirghiz formed 76 per cent. of the population, Taranchis 7 per cent., Russians 14 per cent., and Dungans most of the remainder. Of the Russians, 26,500 were Cossacks, about 15,000 were numbered in the military forces serving in the province, and 53,110 were peasants and artisans in towns. The province is divided into 6 districts, the chief towns of which are: Vyernyi, capital of the province (22,982), Jarkent (16,372), Kopal (2842), Pishpek (6622), Prjevalsk (7987), which has superseded Tokmak, and Sergiopol (1044). The standard of education is low; in 1899 there were only 82 primary schools, attended by 8817 boys and 2473 girls. The chief occupation of the Russians, the Taranchis, and the Dungans, and partly also of the Kirghiz, is agriculture. In an average year the crops yield about 137,500 cwt. of wheat, 47,500 cwt. of barley, 103,750 cwt. of oats, 61,250 cwt. of millet, 3075 cwt. of rice, and 5250 cwt. of potatoes—a supply which more than satisfies the needs of the population. A variety of oil-bearing plants and

green fodder, as also hemp, flax, poppies, &c., are grown. Cattle-breeding is very extensively carried on by the Kirghiz, there being in 1899, 755,000 horses, 425,000 horned cattle, 4,274,000 sheep, 100,000 camels, 282,000 goats, and 15,000 pigs. Orchards and fruit gardens are well developed; the Crown maintains two model gardens. Bee culture is also widely spread, nearly 6700 cwt. of honey being obtained every year. Hunting in the mountains still retains its importance. The factories consist of a few flour-mills, distilleries, tanneries, and tobacco works; but a great variety of domestic trades, including carpet-weaving and the making of felt goods, saddlery, and iron goods, are carried on, both among the settled inhabitants and the nomad Kirghiz. Exports to China are valued at about 2,600,000 roubles annually, imports at a little over 1,000,000 roubles.

Semmelweiss, Ignatius Philippus (1818–1865), Hungarian physician, was born at Buda 17th July 1818, and was educated at the universities of Pest and Vienna. At first he intended to study law, but soon abandoned it for medicine; and such was his promise that, even as an undergraduate, he attracted the attention of men like Skoda and Rokitansky. He graduated M.D. at Vienna 4th April 1844, and in the following June was appointed assistant professor in the maternity department, under Professor Klein. In Klein's time the deaths in this department became portentous, the ratio being rarely under 5·03 and sometimes exceeding 7·45 per cent. Between October 1841 and May 1843, of 5139 parturient women 829 died; giving the terrible death-rate of 16 per cent., not counting those of patients transferred to other wards. It was observed that this rate of mortality prevailed in the students' clinic; in the midwives' clinic it ruled much lower. Mothers, finding themselves in that dreaded quarter, would fall on their knees and pray to be allowed to return to their homes. Profoundly moved by pity and sorrow, Semmelweiss found no satisfactory explanations in such causes as overcrowding, fear, mysterious atmospheric influences, or even contaminated wards; yet that the cause lay in some local conditions he felt certain. The patients would die in rows, others escaping; and women delivered before arrival, or prematurely, would escape. At last, he tells us, the death of a colleague from a dissection wound "unveiled to my mind an identity" with the fatal puerperal cases. The students often came to the lying-in wards from the dissecting-room, their hands cleansed with soap and water only. In May 1847 Semmelweiss prescribed ablutions with chlorinated lime water: in that month the mortality stood at 12·24 per cent.; before the end of the year it had fallen to 3·04, and in the second year to 1·27; thus even surpassing the results in the midwives' clinic. Skoda and other eminent physicians were convinced by these results (*Zeitschrift d. k. k. Gesellschaft der Aerzte in Wien*, J. vi. B. i. p. 107). Klein, however, apparently blinded by jealousy and vanity, supported by other reactionary teachers, and aided by the disasters which then befell the Hungarian nation, drove Semmelweiss from Vienna, and silenced him. Fortunately, at Pest Semmelweiss was appointed obstetric physician in the maternity department, then as terribly afflicted as Klein's clinic had been; and during his six years' tenure of office he succeeded, by antiseptic methods, in reducing the mortality to 0·85 per cent. Semmelweiss was slow and reluctant as an author, or no doubt his opinions would have obtained an earlier vogue; moreover, he was not only tender-hearted but also irascible, impatient, and tactless. Thus it cannot be said that the stupidity or malignity of his opponents was wholly to blame for the tragical issue of the conflict which brought this man of genius within the gates of an asylum 20th July 1865. Strange to say, he brought with him into this retreat a dissection wound of the right hand; and on the 17th of the following August he died of the very disease for the relief of which he had sacrificed health, fortune, and even life itself. For the relations in the order of discovery of Semmelweiss to Lister the reader is referred to the article on LISTER (vol. xxx.). A brief biography of Semmelweiss by Dr Duka was published at Hertford (Austin and Sons) in 1892. (T. C. A.)

Senaar. See SUDAN: *Anglo-Egyptian*.

Seneca Falls, a village of Seneca county, New York, U.S.A. It is situated in 42° 55′ N. and 76° 45′ W., on the river Seneca, and the New York Central and Hudson River and the Lehigh Valley railways, at an altitude of 463 feet. The falls in the river, from which the village derives its name, are 50 feet in height and furnish ample water-power, which has been put to use in the manufacture of woollen goods, machinery, and other articles. Population (1890), 6116; (1900), 6519, of whom 801 were foreign-born.

Senegal, a river of West Africa, entering the Atlantic in 16° N. after a course of about 1000 miles. Explorations have improved our knowledge of the source-region of the river, showing that the Bafing, its chief upper branch, rises in 10° 28′ N., 12° 5′ W., and is joined in about 11° 10′ N. by the Tene, formerly supposed to be the headstream of the Faleme. A little south of 12° the Bafing is a large stream 250 yards wide, and is here separated from the sources of the Faleme by a line of hills 2600 feet high, which send to the latter river four important streams rising in about 12° N. The rise of the Lower Senegal is due to the rains in this source-region, the flood water passing down the Faleme more quickly than down the Bafing owing to its shorter course. From July to October the level of the Senegal shows a series of fluctuations, with, however, a general increase till the end of August or beginning of September, when the maximum occurs. Boats drawing from 1 foot to 2 feet 6 inches can ascend to Kayes from the beginning of June to the middle of November; steamers drawing 4 feet 3 inches, from July to October inclusive; and ocean steamers, lightened so as to draw 11–13 feet, during August and September.

Senegal, a French colony in West Africa, situated between the Gambia on the S., the French Sudan on the E., and the Sahara on the N. It covers about 80,000 square miles and presents no prominent orographic feature. The coast is low and bordered with sandhills. The only important river is the Senegal, which is formed by the confluence at Bafulabe of the Bafing and the Bakhu, the former rising in Futa Jallon, belonging to French Guinea, and the latter in French Sudan. It passes, within the government of Senegal, the towns of Bakel, Matam, Saldé, Podor, and St Louis; near Bakel it receives the Faleme, which flows from south to north.

Senegal is placed under the immediate authority of the governor-general of West Africa, and comprises: (1) four communes with full communal powers (St Louis, Dakar, Goree, and Rufisque), containing a population of about 39,000; (2) nine circles, or territories administered directly, with a population of 61,000; (3) twenty-two countries on the middle and lower river, under the immediate protectorate of France, with about a million inhabitants; (4) autonomous countries north of the Senegal, under the political protectorate (the Moorish tribes Trarza, Brakna, and Duaish), with a population of 80,000. To these districts have to be added the western portion of the Sudan, now in

administrative connexion with Senegal, which has an area of about 120,000 square miles and a population exceeding 2,000,000. Senegal produces, above all, oil-seeds, castor, earth-nut, sesame, and cocoa-nut. The earth-nut, since 1888, has yielded about 30,000 tons a year. Millet, maize, and rice occupy about two-thirds of the cultivated land. On the Lower Senegal there are a model farm and a nursery. Worthy of mention among the products of the country are acacia gum, which the Moors gather in the northern region; the kola-nut; and especially caoutchouc, which is collected in increasing quantities (350 tons in 1898) in the outlying district of Casamance, which projects between Portuguese Guinea and British Gambia. The herds tend to increase: in 1898 there were about 90,000 cattle, 50,000 sheep, 40,000 goats, 3000 camels, besides asses and horses. Gold, iron, quicksilver, and copper are found. Industry is not organized, but the natives carry on weaving, pottery, brickmaking, and the manufacture of trinkets. The total trade, which in 1882 amounted to the value of £1,920,000 sterling, and in 1889 to £2,400,000, had fallen in 1898 to £1,840,000, but by the year 1900 had increased to £3,182,000. The imports from France consisted of tissues and clothing (£120,000), rice (£76,000), wines (£74,000), implements, sugar, hides, and toys; the exports to France were chiefly earth-nuts (£340,000), gums (£160,000), caoutchouc, and feathers. The vessels entered and cleared, with cargo only, at Dakar, Rufisque, and Goree, exceed 100,000 tons annually. Dakar is fortified and classed among the supports of the French navy. Goree is also fortified. Communication along the coast from Dakar to St Louis (160 miles) is by a railway constructed between 1882 and 1885. Inland, there is a river service from St Louis to Podor (3 days), extended in the rainy season as far as Kayar in the Sudan (6 days). Dakar is in regular communication with Marseilles (10 days) and Bordeaux (8 days). The chief towns in French Senegal are: St Louis, the capital, with 20,173 inhabitants, Bakel (3000), Dakar (1200), Goree (2000), and Rufisque (8000).

Senendij. See Kurdistan.

Senussi.—Mohammad El-Mahdi (born in the Cyrenaica 1847, died in Kanem near Lake Chad 1902), son of Es-Seyyid Mohammad Es-Senussi, was a pious Moslem sheikh of North Africa, whose career has been rendered especially remarkable owing to the exaggerated importance attached to his spiritual and secular influence by certain French writers of the past generation. At one time it used to be seriously stated that he flourished as a veiled and awful Moslem pontiff away in the craggy fortress of Siwa, in the oasis of Jupiter Ammon; that he was at the head of a large army, and possessed arsenals filled with unlimited supplies of modern guns and ammunition; that his emissaries, with their secret passwords of the "Rose," were intriguing throughout Turkey as well as in India; and that the day might come when, declaring himself the true Mahdi, or forerunner guided by Allah, he might raise all North Africa against Christianity. These legends of phantom armies, arsenals, and emissaries have come to nought, and there is no proof of gigantic combinations of Islam under his leadership against Great Britain or France. His father, Seyyid Mohammad, of Oran, escaping from the French during the war in Algeria, went to Mecca, and eventually settled in the province of Benghazi, where he built his white hermitage, the Záwia Baidá. Here, in 1847, a son was born, whom he called El-Mahdi (*i.e.*, "He who is led by Allah"), a name not uncommon among the Arabs of North Africa, held both by individuals and families, and meaning nothing more than many names from the Old Testament which are bestowed on Christian children. In 1853 Seyyid removed to Jaghbub (a small oasis some 30 miles west of the Egyptian town of Siwa), where he died in 1857, leaving the young Mahdi to the care of his friends, Amran, Reefi, and others. The peculiarity of the position lay in this: throughout Islam, in every town may be found a Shereef or noble, a Seyyid or lord, claiming descent from the Prophet and recognized as a local leader of society. Senussi El-Mahdi in the desert had no followers; greater lords than he lived in Algeria, and even in Benghazi itself he was of small account. His spiritual influence was, therefore, confined to the camel-men of the caravans across the Sahara, who slowly spread his reputation for quietism and holiness along the string of oases, Ojila-Jalo, Kufra, Borku, into Wadai and Kanem, and continued his work as a reviver of Islam in the central Sudan states. For more than forty years he lived in seclusion at Jaghbub, loyal to the sultan and keeping free from intrigues; but in 1889 he was visited by the pasha of Benghazi at the head of some troops, an incident which showed Senussi that he was no longer safe from intrusion. In 1894 he abandoned North Africa and removed to Borku, and thence to Wadai, where he was welcomed with veneration. The great fact which stands to the credit of Senussi is connected with Wadai, when, in 1888, he urged its sultan to oppose the march westwards of the Mahdi's followers from Khartum. He himself scornfully rejected the Mahdi's overtures, showing the same nobility and sound statesmanship as his fellow shereefs, Abu Fatma and Mirghani, in the eastern Sudan. Whatever was seriously known of Senussi was to his advantage; and just as Wahhabi-ism implies aggressive fanaticism, so does Senussi's name suggest a policy of peace, quietism, and loyalty to constituted authority. Thus, if during the last years of his life he may have enjoyed any slight influence over the wild negro races beyond the Sahara, that influence was for good, in the form of piety and wise counsel. In Egypt he had no followers, nor was there ever a question of his intriguing against the British occupation. In like manner, it is important to understand that the so-called sect of Senussiyeh, if genuine disciples of Senussi, can in no way be hostile to any civilizing mission of trade and prosperity in Nigeria. Senussi was the victim of much slander during his lifetime; and it may be discovered later, when falsehood and exaggeration shall have ceased, that he really tried to live up to his birth-name of El-Mahdi, the servant of Allah, by leaving the savage Beduin and Sudanese, among whom his lot was thrown, a little better for his presence among them. (D. A. C.)

Seoni, a town and district of British India, in the Jubbulpore division of the Central Provinces. The town is 2043 feet above the sea, half-way on the road between Nagpur and Jubbulpore. Population (1891), 11,976. The district of Seoni is part of the Satpura tableland, containing the headwaters of the Wainganga. It is still largely covered with forest, and 42 per cent. of the inhabitants belong to aboriginal tribes. Area, 3198 square miles. Population (1891), 370,767; (1901), 327,217, showing a decrease of 12 per cent., due to the effects of famine. The density in 1901 was 102 persons to the square mile. The land revenue is Rs.1,64,000, the incidence of assessment being less than two annas per acre; cultivated area (1897–98), 574,339 acres, of which 19,268 were irrigated from tanks; number of police, 285; boys at school (1896–97), 3489, being 12·5 per cent. of the male population of school-going age; death-rate (1897), 65·92 per thousand. The principal crops are wheat, rice, millet, pulse, and oil-seeds.

There is another town called SEONI in the Central Provinces, a railway station in Hoshangabad district, situated in 22° 28′ N. and 77° 29′ N. Population (1891), 6779.

Sepsiszentgyörgy, a corporate town of south-eastern Hungary, chief place of the county of Háromszék, 20 miles from Brassó, with 5753 inhabitants in 1891, and 7131 in 1901. It has a normal school, a Calvinist upper gymnasium, a female industrial school, a "Székely" national museum, an orphanage and asylum, a textile factory, &c. In its vicinity are many medicinal baths, the most important being that of Elöpatak.

Seraing, a town of Belgium, in the province, and 5 miles south-west of the city, of Liége by rail. It has acquired a European reputation on account of its vast iron-works (Societé Cockerill) and manufactories, in which more than 10,000 hands are employed. Population (1890), 33,495; (1900), 37,845.

Serajevo, or BOSNIA SERAÏ, the capital of the province of Bosnia, in Austria-Hungary, and the seat of a Roman Catholic bishopric, situated in a narrow valley—closed on the east by a semicircle of rugged hills—on the river Miliatchka, and on the Bosnia Railway, 167 miles south of Bosnisch-Brod and 111 north-north-east of Metkovic. A great part of the town has been rebuilt in the European fashion, and extensive drainage works have been carried out. A telephone service was introduced in 1899. The chief public buildings are the Husref Bey mosque, dating from the 16th century; the Catholic cathedral (1889); the *konak*, or official residence of the governor; the town-hall (1895); the *bezesten*, or market-hall; the museum, containing specially fine antiquarian and natural history collections; the castle, on a rocky eminence commanding a magnificent view of the town and neighbourhood; the Roman Catholic seminary; the school-masters' college; the hospital; and the "association" buildings (1898), with a large hall for public entertainments. The town is famous for its native industries in metals. There are also large potteries, and silk-weaving is carried on. A brewery produces about 900,000 gallons annually. The Government tobacco factory has a large output, and employs over 2000 workpeople. At the mineral baths of Ilidže, near the town, a hydropathic establishment was opened in 1899. Population (1885), 26,268; (1895), 37,713.

Serampur, a town of British India, in the Hooghly district of Bengal, on the right bank of the river Hooghly, opposite Barrackpur; station on the East Indian Railway, 12 miles from Howrah. Population (1881), 25,559; (1891), 35,952. Formerly a Danish settlement, it was sold to the British in 1845. It was the home of the Baptist mission founded by Carey. A jute mill, with 354 looms and 7260 spindles, employs 2700 hands. Paper is manufactured. There is a public library. The famous Baptist mission press has been transferred to Calcutta, but a training college is still maintained by the mission.

Serapion. See SACRAMENTARY OF SERAPION.

Serdobsk, a district town of Russia, in the government, and 129 miles north-west of the town, of Saratoff, on a branch of the railway from Ryazañ to the Urals. It has trade in grain and flour, of both of which over 32,000 tons are exported every year. Population (1897), 12,721.

Serena, a town of Chile, capital of the province of Coquimbo and of the department of Serena, 9 miles east-north-east of Coquimbo, on the Pacific. Population (estimated), 17,230. It has a court of appeal, with jurisdiction in the provinces of Atacama and Coquimbo, and is the residence of a bishop. It has a large hospital, an orphan asylum, lazaretto, and poorhouse.

Séres, SERROS, or SIROS, chief town of a sanjak in the vilayet of Macedonia, European Turkey, situated on Lake Talhino, an expansion of the Strouma, in one of the most fertile districts of the empire, 43 miles north-east of Salonica. It consists of the old town, *Varoch*, situated at the foot and on the slope of the hill crowned by the old castle, and of the new town built in the European fashion on the plain, and forming the commercial centre. The town is the main entrepôt of the Turkish cotton trade, and has also manufactures of cloth and carpets. There is a large trade in rice and cereals, and the other exports include tobacco and hides. Population, 30,000, of whom about half are Bulgarians (one-third of them being Mussulmans), nearly one-fourth Greeks, about one-seventh Turks, and the remainder Jews.

Serghinsk, Upper AND **Lower,** two towns of East Russia, in the government of Perm, 43 miles west-south-west of Ekaterinburg. They are noted for their important iron-works, which deal with the production of as many as eighteen mines. UPPER SERGHINSK, which had a population of 8000 in 1897, yields annually over 8050 tons of pig iron and 12,100 tons of steel. LOWER SERGHINSK, with 14,000 inhabitants, yields about 7250 tons of pig iron and 14,500 tons of steel. The latter is well built, has a monument to Alexander II., and is well provided with schools. Mineral waters (sulphurous) are found close by.

Sergipe, a state of Brazil, for the most part situated between 9° 5′ and 11° 28′ S. and 36° 17′ and 38° 7′ W. Area, 15,000 square miles. Population in 1872, 176,243, and in 1890, 461,307; but in 1900 it was estimated at less than 400,000, of whom three-fourths were negroes and half-castes. Europeans numbered only 500 to 600. The capital, Aracajú, has 20,000 inhabitants (1900). Amongst other towns are Estancia, Itabaiana, Lagarto, Larangeiras, Maroim, S. Christovao, Capella. Sugar, cotton, manioc, maize, tobacco, beans, and indiarubber are the crops chiefly grown. The exports (two-thirds sugar) were valued at £454,000 in 1900, and the imports (by sea) at £353,000. There is a railway extending north from Aracajú as far as Capella, and west as far as Simão Diaz.

Serpa Pinto, Alexandre Alberto de la Rocha (1846-——), Portuguese explorer, was born at the castle of Polchras, on the Douro, 10th April 1846. After accompanying his father to America, he was sent in 1858 to the military school at Lisbon. Entering the army in 1864, he served in the colony of Mozambique, and being promoted major was given the command of an important expedition into South Africa. Starting from Benguela on the 12th November 1877, he explored the basins of the Kwando and Zambesi, and followed the latter river to Victoria Falls, and then went southwards to Shoshong, Pretoria, and Durban, 1879. He was thus the fourth explorer who traversed the African continent from west to east, and was rewarded in 1881 with the large gold medal of the Geographical Society of Paris. The account of his travels appeared in English under the title *How I Crossed Africa*, 2 vols., London, 1881. In 1884 he attempted, with less success, the exploration of the regions between the Mozambique and Lake Nyasa. Appointed governor of Mozambique in 1889, he endeavoured to bring the Matabele territory under the jurisdiction of Portugal, but his Government, finding that it could not support his pretensions against the veto of Great Britain, yielded to the ultimatum of 12th January 1890, and recalled him.

Serrano y Dominguez, Francisco, DUKE DE LA TORRE AND COUNT OF SAN ANTONIO (1810–1885), Spanish marshal and statesman, was born in the island of Leon at Cadiz 17th December 1810. His father was a general officer and a Liberal. Serrano began his studies at Vergara in the Basque provinces, became a cadet in 1822, cornet in 1833 in the lancers of Sagunto, passed into the carabineers in 1829, and when the Carlist agitation began in 1833 he exchanged into the cuirassiers. He formed part of the escort which accompanied Don Carlos, the first pretender and brother of Ferdinand VII., to the frontier of Portugal. As aide-de-camp of Espoz y Mina, then under the orders of Generals Cordoba and Espartero, in the armies of Queen Isabella, Serrano took such an active part in the Carlist war from 1834 to 1839 that he rose from the rank of captain to that of brigadier-general. His services obtained for him the Cross of San Fernando and many medals. In 1839 he was elected a member of Cortes for the first time by Malaga, and in 1840 he was made a general of division and commander of the district of Valencia, which he relinquished to take his seat in congress. From that day Serrano became one of the chief military politicians of Spain. In 1841 he helped Espartero to overthrow the regency of Queen Christina; in 1843 at Barcelona he made a *pronunciamiento* against Espartero; he became minister of war in the Lopez Cabinet, which convoked the Cortes that declared Queen Isabella of age at fifteen, served in the same capacity in an Olozaga cabinet, sulked as long as the Moderados were in office, was made a senator in 1845, captain-general of Granada in 1848, and from 1848 to 1853 lived quite apart from politics on his Andalusian estates or travelling abroad. He assisted Marshal O'Donnell in the military movements of 1854 and 1856, and was his staunch follower for twelve years. O'Donnell made him marshal in 1856 and captain-general of Cuba from 1859 to 1862; and Serrano not only governed that island with success, and did good service in the war in Santo Domingo, but he was the first viceroy who advocated political and financial reforms in the colony. On his return to Spain, he was made duke de la Torre, grandee of the first-class, and minister of foreign affairs by O'Donnell. Serrano gallantly exposed his life to help O'Donnell quell the formidable insurrection of 22nd June 1866 at Madrid, and was rewarded with the Golden Fleece. At the death of O'Donnell, he became the chief of the Union Liberal, and as president of the senate he assisted Rios Rosas to draw up a petition to Queen Isabella against her Moderado ministers, for which both were exiled. Nothing daunted, Serrano began to conspire with the duke of Montpensier, Prim, and Sagasta; and on 7th July 1868 Gonzalez Bravo had Serrano and other generals arrested and taken to the Canary Isles. There Serrano remained until Admiral Topete sent a steamer to bring him to Cadiz on 18th September of the same year. On landing he signed the manifesto of the revolution with Prim, Topete, Sagasta, Martos, and others, and accepted the command of the revolutionary army, with which he routed the troops of Queen Isabella under the orders of the marquis of Novaliches at the bridge of Alcolea. The queen fled to France, and Serrano, having entered Madrid, formed a Provisional Government, convoked the Cortes Constituyentes in February 1869, and was appointed successively president of the executive and regent. He acted very impartially as a ruler, respecting the liberty of action of the Cortes and cabinets, and bowing to their selection of Amadeus of Savoy, though he would have preferred Montpensier. As soon as Amadeus reached Madrid, after the death of Prim, Serrano consented to form a coalition Cabinet, but it kept together only a few months. Serrano resigned, and took the command of the Italian king's army against the Carlists in North Spain. He tried to form one more cabinet under King Amadeus, but again resigned when that monarch declined to give his ministers dictatorial powers and sent for Ruiz Zorilla, whose mistakes led to the abdication of Amadeus on 11th February 1873. Serrano would have nothing to do with the federal republic, and even conspired with other generals and politicians to overthrow it on 23rd April 1873; but having failed, he had to go to France until General Pavia, on the eve of his *coup d'état* of 3rd January 1874, sent for him to take the head of affairs. Serrano assumed once more the title of president of the executive; tried first a coalition Cabinet, in which Martos and Sagasta soon quarrelled, then formed a Cabinet presided over by Sagasta, which, however, proved unable to cope with the military and political agitation that brought about the restoration of the Bourbons by another *pronunciamiento* at the end of December 1874. During the eleven months he remained in office Serrano devoted his attention chiefly to the reorganization of finance, the renewal of relations with American and European powers, and the suppression of revolt. After the Restoration Serrano spent some time in France, returned to Madrid in 1876, attended palace receptions, took his seat as a marshal in the senate, coquetted a little with Sagasta in 1881, and finally gave his open support to the formation of a dynastic Left with a democratic programme defended by his own nephew, General Lopez Dominguez. He died in Madrid 26th November 1885, twenty-four hours after Alphonso XII. (A. E. H.)

Servia, an independent kingdom in the Balkan Peninsula, lying between Austria-Hungary on the N. (from which empire it is divided by the rivers Sava and Danube), the Turkish province Kossovo and a part of Macedonia on the S., Bosnia on the W., and Bulgaria on the E. Previous to the Treaty of Berlin (1878) it was an autonomous principality, vassal to the sultan of Turkey; after that treaty it became an independent principality, and was proclaimed a kingdom in 1883. According to the measurements and computation of the Servian General Staff, the area of Servia is 4,858,940 hectares (or 18,782 square miles). Of this area, 3,418,768 hectares, or 70·36 per cent. of the total area, are considered as productive, and 1,440,172, or 29·64 per cent., as unproductive. In 1897 there were 1,805,935 hectares under actual cultivation. The forests (mostly oak and beech) occupied in that year 481,214 hectares.

Population.—Official censuses were taken in the years 1884, 1890, 1895, and 1900, giving the following results:—

	Male.	Female.	Total.
1884	972,973	928,763	1,901,736
1890	1,109,885	1,052,076	2,161,961
1895	1,186,594	1,125,890	2,312,484
1900	1,282,625	1,211,145	2,493,770

At the date last quoted the rural population numbered 2,035,364, or 81·6 per cent. of the total, and the urban population 458,406, or 18·4 per cent. of the whole. The population increased from the beginning of 1885 to the end of 1900 by 592,034 inhabitants, which gives an annual increase of 1·83 per cent.

The number of foreigners, or inhabitants belonging to other nationalities, was found to be 206,017 in 1890 and 229,002 in 1895. Their number therefore increased by 11·6 per cent. in the period 1890–95. In the last-named year Jews numbered 5048, Germans 6451, Gypsies 46,212, Rumanians (Wallachians) 160,187. There were then only 14 Englishmen settled in Servia. According to religion there were in 1895: Orthodox (Eastern Church) 2,281,018, Mahommedans 14,414, Roman Catholics 10,410, Jews 5102, Protestants 1002. For the period of ten years from 1881 to 1890 (inclusive), for every 1000 inhabitants there were born annually, on an average, 44·10 boys and 43·93 girls. For the same period the number of deaths among every 1000 inhabitants was annually, on an average, 25·15 males and 24·89 females, which figures give

an average of 50 per 1000 inhabitants. From the year 1885 to 1891 the average surplus of the births over the deaths was 18·15 per 1000 inhabitants. During the five years 1893–98 the annual average surplus of births over deaths amounted to 16 per 1000. In the year 1900 the birth-rate was 42 per 1000, the death-rate 23·3 per 1000, and the marriage-rate 12·5 per 1000, of the population. Although Servia is one of the most thinly populated countries in Europe, having only 133 inhabitants to the square mile, the density of its population is greater than in the other Balkan States.

Education.—Education is free, the teachers and professors being paid either by the municipalities or the State. Government gives numerous bursaries to poor but gifted students in the middle and higher schools, and also to young men who have distinguished themselves in the higher schools and wish to complete their education by study at foreign universities. Attendance at elementary schools is compulsory for boys and girls from their seventh to their twelfth year, but in the villages, with their scattered houses and sparse population, it has been found impossible to insist on the strict execution of the law. In 1899 there were over 1100 elementary schools in Servia, giving one school to every 2270 inhabitants. Girls and boys in the villages go to the same school, but in towns they have separate schools. About 85,000 children are enrolled at the commencement of every school year. Besides the elementary schools, there are some 30 middle schools, mostly gymnasia with more or less classical instruction. There are also several special schools: 1 theological, 2 training schools for teachers, 2 commercial, 1 agricultural, 1 for viniculture, and 2 for weavers. There is an excellent military academy in Belgrade. The highest scientific instruction is given in the so-called *Velika Shkola* ("the Great School") at Belgrade, which is practically a university with 463 students in 1899, but only three faculties: law, philosophy, technical science. In 1899 a Royal Commission was appointed to propose the ways and indicate the means by which the Belgrade Velika Shkola might be transformed into a regular university on the German model. At the census of 1895 it was found that there were 268,759 males and 52,463 females who could read and write. Deducting the number of children up to the sixth year from the rest of the population, only 280·5 men and 58·3 women per 1000 inhabitants could read and write. It has been found that the present system of education furnishes only candidates for employment in the State and municipal services, and barristers and solicitors. As the opportunity for employment in these services is limited, every year a considerable number of young men are without occupation; therefore the Government, since 1897, has been trying to render the system of education less classical and more practical.

Church.—The Servian Church belongs to the group of the Eastern Orthodox (Greek) Churches, but is otherwise independent and self-governing. The highest Church authority is the Bishops' Council or Synod, presided over by the Metropolitan of Servia. There are altogether five dioceses or bishoprics: Belgrade, Schabatz, Nish, Zicha, and Timok. The Archbishop of Belgrade is the Metropolitan of Servia. There are 48 monasteries in Servia, of which Studenitza, built in the 13th, and Manassiya, built in the 15th century, are by far the most interesting.

Finance.—Up to the proclamation of independence, in virtue of the Berlin Treaty (1878), Servian finances were in a somewhat primitive, but, on the whole, healthy condition. The principal revenues were derived from the customs, excise, and a sort of poll tax. The Government required the town and village communities to pay into the State Treasury 30 dinars per head of the able-bodied citizens living in the community, and the municipal board made repartition of the total amount, due to the Government, from its citizens according to their estimated wealth or earnings. That system yielded without the slightest difficulty about £750,000 annually. The State revenue from all sources was in 1879 19,780,929 dinars (£791,235), while the expenditure did not exceed 20,206,410 dinars (£808,256). But among the conditions on which the Congress of Berlin granted independence and accession of territory to Servia, were that she should construct her part of the international railway to Constantinople and to Salonica, and pay the Turkish landowners an indemnity for the estates which had been taken from them and divided among their old tenants. This and the necessity of indemnifying the people from whom, during the wars with Turkey (1876 and 1878), requisitions had been taken and money borrowed, forced the Government to enter the European financial markets. Up to that time (1881) Servia had practically no public foreign debt, although it owed Russia about 6 million dinars lent privately for war preparations, and to its own people about 8 million dinars taken by a forced internal loan for war purposes. The first public loans were made in 1881 by French banks at 71¾ for 5 per cent. bonds, and the expenditure had to be immediately increased to 31 million dinars. The introduction of new taxes and the reorganization of the financial administration of the country could not keep pace with the increase of public expenditure, chiefly because the National Assembly was for some time reluctant to replace the old system of direct taxation by a more modern system. When in 1884 the new law of taxation was adopted, it failed to realize the expectation of largely increased revenue, because the financial administration could not be speedily reorganized. The situation became so serious that the three principal banks—the Imperial Ottoman Bank of Paris, the Berliner Handels-Gesellschaft of Berlin, and the Länderbank of Vienna—which were financing the Servian loans on the Continental markets, thought it necessary to consult with the Government about the best means to place the finances on a healthy basis. The result of the conferences (held in Carlsbad in June 1895) was the adoption of a new scheme by which the Government gave to the bondholders additional securities and two seats on the Board of Administration of Revenues, the bondholders at the same time accepting the new 4 per cent. Unified Bonds in exchange for their old 5 per cent. bonds. Since this conversion operation, the finances have rapidly improved.

Very few countries have to show such a rapid increase of State expenditure and revenue as Servia during the last 20 years of the 19th century, as will be seen from the following table:—

	1871.	1881.	1891.	1900.
	£	£	£	£
Expenditure . .	550,132	945,647	2,290,450	2,931,060
Revenue . . .	520,448	829,785	2,332,069	2,934,340

The king's civil list amounts to £48,000. The expenditure on national education rose from £58,522 in 1871 to £183,863 in 1899. The expenditure on the sanitary service increased from £3730 to £63,597 in 1899. The military expenditure rose from £147,372 in 1871 to £800,000 in 1900. The interest on the national debt, which in 1881 did not exceed £375,000, rose gradually every year, until in 1900 it amounted to £808,000.

On the 31st December 1899 the National Debt amounted to a total of 420,295,000 dinars (£16,812,000), and was composed of the following items:—

	Dinars.
2 per cent. Premium Loan, 1881	29,445,000
Tobacco Lottery bonds, 1888	9,600,000
4 per cent. Unified (Conversion) Loan, 1895 .	351,250,000
5 per cent. Railway Exploitation Loan, 1899 .	30,000,000

Besides this, the Government owes the National Bank of Servia £400,000, which temporary loan is to be repaid in instalments of 1,000,000 dinars a year.

Defence.—There are no modern fortresses, the citadels of Belgrade, Smederevo, Nish, and Pirot being mediæval

constructions. But some strategic points on the Bulgarian frontier were between 1889 and 1899 fortified by earthworks. Servia's defensive force comprises the standing army and the national army. The former consists of 60 battalions, divided into 5 divisions, every man between 20 and 25 being obliged to serve in the barracks for 2 years (reduced to 1½ year by law of 1st February 1901). The national army consists of two classes: the first class is composed of men between 30 and 40 who have served in the standing army, and the second class is formed of men between 40 and 47 years of age. The first class of the national army gives 60 and the second 40 battalions. In the time of peace there are not more than 20,000 men of the standing army serving with the colours. On the war footing Servian forces consist of some 160 battalions of infantry, 6 regiments of cavalry, and 120 batteries of 6 field guns each. In 1899 the Government ordered 120,000 Mauser magazine rifles from Germany.

Agriculture.—Servia is essentially an agricultural and cattle-producing country. Nearly 90 per cent. of the whole population are occupied in agricultural pursuits. The characteristic feature of the country is the almost utter lack of large farms, the arable land being divided in small holdings, not exceeding, on an average, 20 acres. The small holdings are in themselves a hindrance to modern agricultural progress, inasmuch as small farmers are not in a position to buy the latest and most improved implements. But there is an additional impediment in the fact that generally the lots of ground belonging to one household or family do not lie together, but are dispersed in different, very often distant, parts of the village land. From ancient times the Servians have had a special institution called "Zadruga," which is an association of all the near and distant members of the same family into one co-operative organization under one chief (generally the oldest or otherwise most experienced member of the family). Usually all the members of the Zadruga lived within the same enclosure, in small wooden houses built around the central house inhabited by the "stareshina" (chief). Under the direction of the stareshina all the members of the association used to work together, the products of their joint labour belonging to the whole Zadruga and not to the individual members. Zadrugas were very prosperous, as they had always a sufficient number of hands at command, and were able to obtain better implements and cattle. But with the establishment of order and security, the Zadrugas began rapidly to disappear, and at the end of the 19th century very few remained. Of course this breaking up involved still greater parcelling of the ground. During the five years 1894–99 a new stimulus was given to agriculture by the encouragement which King Alexander personally extended to the establishment of agricultural associations, or rural co-operative associations on the Raiffeisen principles. The object of these associations is principally to facilitate the acquisition of improved implements and better breeds of cattle. In 1899 there were 187 such associations. Another serious drawback to the economic position is that Servia has no seaboard, and that it is at some distance from the nearest export harbours (Galatz, Salonica, Fiume). Still, agriculture made unmistakable progress, especially during the last ten years of the 19th century. The following tables, compiled from official statistics and showing in hectares (hectare = 2·47 acres) the area under cultivation, will give confirmation to this statement:—

	1867.	1889.	1897.
Maize	340,606	302,700	448,334
Wheat	...	319,820	500,321
Meadows	254,722	358,164	355,051
Vineyards	32,855	43,304	68,330
Orchards	56,011	59,461	97,971

The following two tables will give an idea of the prosperity of Servia as an agricultural country:—

	1890.	1895.
Number of households (families)	348,257	375,196
Number of households possessed of landed property	257,280	300,275
Number of households without landed property	90,977	74,921
Number of households which possessed cattle	267,466	284,065
Hectares under cultivation	1,140,088	1,805,935

Live Stock.	1890.	1900.
Horses	163,391	180,871
Oxen and cows	819,251	942,087
Sheep	2,963,904	3,013,644
Pigs	908,603	940,609
Goats	502,738	425,565
Beehives	124,600	1895. 167,765

The live stock of Servia represented the following value in dinars in the years specified:—

	1890.	1895.
	Dinars.	Dinars.
Horses	12,285,608	24,610,174
Cattle	61,015,365	78,434,045
Buffaloes	1,453,690	395,272
Pigs	10,105,698	14,497,018
Sheep	20,374,668	19,467,912
Goats	3,466,213	2,925,602
Beehives	794,310	1,763,764
Total value	109,495,552	142,093,787

Commerce.—The movement of Servian commerce will be seen from the following table, compiled from official statistics, values being given:—

Year.	Imports.	Exports.
	£	£
1879	1,652,680	1,555,240
1889	1,393,720	1,562,240
1899	1,857,144	2,629,775
1900	2,161,100	2,661,000

Of the total imports, fully 59 per cent. come from Austria-Hungary, 12¼ per cent. from Great Britain, and 10¾ per cent. from Germany. The principal articles of import are: cotton and linen textiles (£388,996 in 1899), wool and woollen textiles (£181,104), iron, copper, brass manufactures (£201,094), sugar, coffee (£136,749). The direct import of cotton yarn and textile from Great Britain does not exceed £110,000 per annum. Of the total exports, about 85 per cent. go to Austria-Hungary. There is no direct export to Great Britain, but it is generally believed that some of the Servian wheat and maize, exported down the Danube to Galatz, finds its way to England, as well as that prunes, which are exported to Germany, find buyers in London. The exports consist principally (42 per cent.) of agricultural produce and live stock, the value in 1899 being £1,177,043, of which £658,466 was for cereals, chiefly wheat and maize, and £447,912 was for prunes. Next in point of value come hides (£126,291), bacon, cordage, copper and other metals.

Railways.—In 1879 Servia possessed no railway. In 1881 it began the construction of its part of the great line connecting central and western Europe with Constantinople and Salonica, and finished it in 1886. In 1899 Servia had 332 miles of railways belonging to the nation and worked by the Government. For the construction of these railways she expended £4,206,080, and an extra amount of £566,480 for rolling-stock. The total receipts from the railway traffic in 1898 were £247,705, while the total expenditure amounted to £162,863, giving a net revenue of £84,842; in 1900 the gross receipts amounted to £255,900. For the construction of a network of 600 miles of light railways connecting all parts of the country with the principal (international) line, Belgrade Nish, the Government granted in 1899 a concession to an English syndicate. One of the aims of this railway programme was to connect the Servian railways on one side with the Bosnian network (and through that with Dalmatia and the Adriatic), and on the other side with the Rumanian railways, and through them with the Russian. A convention between Rumania and Servia concerning the building of a railway bridge across the Danube, connecting the two systems, was signed in 1898.

Banks.—In 1879 Servia had only three joint-stock banks. In 1883 the National Bank of the Kingdom of Servia was created, with a nominal capital of £400,000 (of which £200,000 has been paid up), with power to increase it to £800,000, and with a privilege of issuing notes secured by at least 33 per cent. in cash (gold and silver). The annual turn-over of the National Bank reached £10,000,000 in 1898. In the beginning of December 1899 the

bank had notes in circulation to the value of £1,440,000, covered by £700,000 in gold and silver. Besides the National Bank, 72 small local joint-stock banks have been created in the period between 1880 and 1899. The total paid-up capital of the three banks existing in 1879 did not exceed together £72,000, whereas the total paid-up capital of the banks existing in 1899 reached the amount of £800,000. In addition to this, about £300,000 has been invested in a few industrial enterprises since 1890. The total annual turnover of the three banks existing in 1879 did not exceed £1,400,000, whereas the total of the annual business of the 75 banks existing in 1898 amounted to £65,665,000.

HISTORY.

The kingdom of Servia is only one part of the territory inhabited by the Servians, the other parts being northern and north-western parts of Macedonia, the Turkish province of Kossovo, Bosnia, Herzegovina, Montenegro, Dalmatia, Croatia, Syrmia, and the Hungarian districts between the river Tisza and the Danube. Servia lost its independence in 1462, and became a Turkish vilayet under the direct rule of Turkish pashas. Servia remained a Turkish pashalik until the rising under Tzrni Gyorgyé, otherwise Kara-Gyorgyé (Black George) in 1804, who succeeded in driving away the Turks and in organizing self-government. This partial independence, however, was completely lost, and Servia was reconquered by the Turks, when Russia concluded with the Porte the Peace of Bucharest in 1812 without making sufficient provision for the safety of its ally Servia. Voyvode (military chieftain) Milosh Obrenovich, who remained in the country after Kara-George and other voyvodes left Servia, headed a new national rising against the Turks on Palm Sunday 1815. By victories in the field and by clever negotiations Milosh succeeded in obtaining from the Sultan Mahmud II. the grant of internal autonomy as early as in 1820. This important result, obtained by the Servians without any foreign support, was placed on an international foundation by Russia in the Treaty of Adrianople, 1829. When in 1839 Prince Milosh Obrenovich I., and (after the death of his elder son, Milan Obrenovich II.) in 1842 his younger son, Prince Michael Obrenovich III., were obliged to leave the country, the Servians elected Alexander Karageorgevich (the younger son of Kara-George) to be prince of Servia. But in 1859 he was dethroned by the National Assembly, and the old Milosh Obrenovich I. recalled. It is a noteworthy fact that Milosh as early as in 1836 made efforts to enter into political and commercial relations with England. One of the causes of his dethronement in 1839 was his attempt to obtain British support against Russia's encroachments in the internal affairs of Servia. Prince Michael Obrenovich III. (whose wife, Princess Julia, *née* Countess Hunyady, spent in 1863 and 1864 a considerable time in London on a political mission) also appealed to England when he grew impatient of the Russian treatment of Servian interests. But Prince Milan Obrenovich IV., who succeeded to the Servian throne (on the assassination of his cousin, Prince Michael, by the partisans of the Kara-George dynasty, 10th June 1868), was educated in the political school favourable to Russia, and faithfully and unhesitatingly followed the Russian lead up to the conclusion of the San Stefano preliminary treaty. By that treaty Russia, desiring to create a great Bulgaria, took within its limits districts inhabited by Servians, and considered by the Servian politicians and patriots as the natural and legitimate inheritance of their nation. This act of Russia created great dissatisfaction in Servia, and became the starting-point for a new departure in Servian politics. At the Berlin Congress the Servian plenipotentiary, M. Ristich, in vain appealed to the Russian representatives to assist Servia to obtain better terms. The Russians themselves advised him to appeal to Austria and to try to obtain her support. The utter neglect of the Servian interests by Russia at San Stefano, and her evident inability at the Berlin Congress to do anything for Servia, determined Prince Milan to change the traditional policy of his country, and instead of continuing to seek support from, and to follow exclusively, Russia, he tried to come to an understanding with Austria-Hungary concerning the conditions under which that Power would give its support to Servian interests. This new departure was considered by the Russians—especially by those of the Panslavonic party—almost as an apostasy, and it was decided to oppose King Milan and his supporters, the Progressives.

Milosh Obrenovich I.

Milan IV.

Relations with Russia and Austria.

The political history of Servia from 1879 to the abdication of King Milan on 3rd March 1889 was an uninterrupted struggle between King Milan and the Progressives on one side, and Russia with her adherents, the Servian Radicals, on the other. In that incessant struggle King Milan and his Government were badly handicapped by several unfortunate circumstances. To fulfil the engagements accepted in Berlin and the conditions under which independence had been granted to Servia, railways had to be constructed within a certain time, and the Government had also to pay to the Turkish landlords in the newly-acquired districts an equitable indemnity for their estates, which were divided among the peasants. These objects could not be attained without borrowing a considerable amount of money in the European markets. To pay regularly the interest on the contracted loans the Government of King Milan had to undertake the unpopular task of reforming the entire financial system of the country and of increasing the taxation. The expenditure increased more rapidly than the revenue. Deficits appeared, which had to be covered temporarily by new loans, and which forced the Government to establish monopolies on salt, tobacco, matches, mineral oils, &c. Every such step increased the unpopularity of the Government and strengthened the Opposition. An attempt on the life of King Milan was made in 1882, and an insurrection in the south-eastern districts was started in 1883. But the majority of the people, and especially the regular army, remained loyal to the king, and the revolt was quickly suppressed. Then, unfortunately, the union of Bulgaria and Eastern Rumelia inspired King Milan and his Government with the notion that either that union must be prevented, or that Servia should obtain some territorial compensation, so that the balance of power in the Balkan Peninsula might be maintained. This view, which did not find support anywhere outside Servia, led to the war between Servia and Bulgaria (November 1885), in which the Servians were defeated at Slivnitza and had to abandon Pirot, whilst the further advance of the Bulgarian army on Nish was stopped by the intervention of Austria-Hungary. An honourable peace was concluded between the two contending Powers in March 1885. All these misfortunes, however, failed to upset King Milan and his Government. Then came the unhappy events connected with Milan's domestic trouble and his divorce from Queen Natalie. That domestic misfortune was cleverly exploited by King Milan's enemies in the country and abroad, and did him more harm than all other political mistakes together. He tried to retrieve his position in the country, and succeeded in a great measure, by granting a very liberal Constitution (December 1888) at a time when all agitation for a new Constitution had been given up. Then, to the great astonishment of the Servians and of his Russian enemies, King Milan voluntarily abdicated, placing the Government of the country in the hands of a regency during the minority of his only son Alexander, whom he proclaimed king of Servia on 6th March 1889.

The Progressive régime.

War with Bulgaria.

King Alexander.

The leading man of the regency was Yovan Ristich, a man of great experience and ability, who had already been regent during the minority of King Milan (1868–71). Although he had been since 1868 the leader of the Liberal party, he showed himself, as regent, extremely Conservative. The new Constitution was the embodiment of Radical principles, and the numerically strongest party in the country was Radical. The National Assembly was composed, therefore, almost exclusively of Radicals, and the Government was Radical likewise. From the very beginning the Conservative regency and the Radical Government distrusted each other. The Government was not strong enough to resist the clamour of their numerous partisans for participation in the spoils of party warfare. Political passions, which had been stirred up by the long struggle against King Milan's Progressive régime, could not be allayed so quickly; and as the anarchical element of the Radical party obtained the ascendancy over the more cultured and more moderate members, all sorts of political excesses were committed. The old system of borrowing money to cover the yearly deficits was continued, and the budget of expenditure went on increasing from year to year. The administration lost all authority, and was demoralized by the precariousness of the position of the officials, who might be transferred or even dismissed at any moment at the instance of local politicians. The police also became paralysed and brigandage became rife. It was evident that the country was financially and politically in a worse plight than before. The Radical Government thought to strengthen their position by letting the National Assembly vote a law prohibiting the return of the king's father to Servia, and expelling by force from Belgrade the king's mother, Queen Natalie. But such laws and such acts only embittered political passions and greatly encouraged the adherents of Prince Peter Karageorgevich, who, having married the eldest daughter of Prince Nicholas of Montenegro and living at Cettigne, was supposed to enjoy the support of Russia. The political situation became still more confused when on the death of the third regent, General Kosta Protich, the Government tried to force the regency to accept in his stead M. Pashich, the leader of the Radical party. The regents thereupon dismissed the Radical Cabinet and called the Liberals to the Government (August 1892). The Liberal Cabinet dissolved the Radical National Assembly, and at the general elections used very great pressure to secure a Liberal majority. In this they did not succeed, and the situation became hopelessly entangled by the fact that the National Assembly was Radical, the Government Liberal, and the regency practically in all its tendencies Conservative. The legislative machinery as well as the administration of the country was thus completely paralysed. Then the young king Alexander, who was supposed to be occupied

The Regency.

exclusively with his studies and to take no interest in the political turmoil, suddenly stepped in, proclaimed himself of age (although at that time only in his seventeenth year), dismissed the regents and the Liberal Cabinet, and formed his first Cabinet from among the moderate Radicals (13th April 1893).

The King's Administration.

The moderate Radicals quickly showed themselves unable to do any serious work. They were fettered by the dissatisfaction of the Left wing of their own party. To satisfy the extreme Radicals they had to impeach the members of the last Cabinet. This increased the bitterness of the Liberals, who, though not so numerous as the Radicals, included in their ranks more men of wealth and culture. Political passions were again in full blaze. The licentiousness of the press knew no bounds, and the king's parents and the king himself were constantly attacked. The anti-dynastic party raised its head again, and in many Radical prints the expulsion of the reigning dynasty and its replacement by the Karageorgevich were more than hinted at. At the same time reports were reaching King Alexander that Russia was discussing with the leaders of the extreme Radicals the conditions under which a Russian grand-duke was to be proclaimed king of Servia. In such circumstances King Alexander thought best to invite his father the ex-King Milan (who was living in Paris) to his side, and to use his great knowledge of men and his political experience. In the beginning of January 1894 King Milan arrived in Belgrade. The Radical Cabinet resigned and was replaced by a Cabinet composed of politicians standing outside the political parties. In June the Radical Constitution of 1888 was suspended, and in its place the Liberal (so-called, but in reality very Conservative) Constitution of 1869 was re-established.

Ex-King Milan's return.

Under that Constitution it became possible for the Government to infuse new confidence into the administration, and at the general election to obtain a majority of Conservative members in the National Assembly. The nation was evidently tired of the violent agitations of recent years. A natural reaction against the Radical excesses set in, and gave rise to Conservative, even somewhat reactionary, legislation. The duration of the legislature was extended from three to five years; the liberty of the press was curtailed by the enactment that proprietors of political papers must make a deposit of 5000 dinars (£200), and that the editors must have completed their studies at a university; the laws on *lèse-majesté* were made more severe. After the advent of the Cabinet of Dr Vladan Georgevich (October 1897) persistent and successful efforts were made to improve the country's financial and economic condition. The violent party strife which from 1880 to 1895 had absorbed the best energies of the country and paralysed every serious and productive work, ceased almost completely, and the nation as a whole turned to improve its agriculture and commerce. The sustained improvement in the political and commercial situation was not influenced materially by the temporary excitement in consequence of the attempt on the life of King Milan (6th July 1899), and of the State trial of several prominent Radicals accused of having conspired for the overthrow of the dynasty. One remarkable feature in the foreign policy of Servia in the last years of the 19th century was that after King Milan was appointed commander-in-chief of the Servian regular army (December 1897), Russia and Montenegro practically, although not formally, broke off their diplomatic relations with Servia, while at the same time the relations of that country with Austria-Hungary became more friendly than under the Radical régime. All this was suddenly and radically changed when in July 1900 King Alexander married Mme Draga Maschin, once lady-in-waiting to his mother Queen Natalie. He threw himself into the arms of Russia, forbade his father Milan to return to Servia, and followed faithfully Russian guidance in all questions of foreign policy. To strengthen his position in the country he gave a sufficiently liberal Constitution in April 1901, establishing for the first time in the history of Servia a Parliament with two Houses (Skupshtina and Senate).

Constitution of 1869 re-established.

King Alexander's marriage.

LITERATURE.

It cannot be said that in the last quarter of the 19th century the Servian nation produced either a great poet or a great artist. But when it is remembered that in the first quarter of that century Servians were only oppressed Turkish rayahs, absorbed in desperate attempts to obtain the simplest conditions for safety of life and property, it must be admitted that their intellectual activity towards the end of the 19th century is at least noteworthy. In Servia the centre of all scientific efforts in historical and archæological researches in the period from 1844 to 1883 was the Srpsko Ucheno Drushtvo (Servian Learned Society), Belgrade, with its periodical *Glasnik*. This society, which rendered valuable services by its collection of historical documents, has been merged into a new and more ambitious organization called The Royal Servian Academy, established in 1883 and reorganized in 1894. The essays and papers read before the Academy are published in its periodical *Glas* (*The Voice*), while historical and archæological materials are printed in another annual, the *Spomenik* (*Memoir*). Among the Servian Academicians, since the death of Dr Joseph Pancic (who was the first president of the Academy and was well known throughout Europe for his botanical researches in the Balkan Peninsula), M. Stoyan Novakovich took a prominent place by his philological and historical researches, and especially by his classical edition of, and learned commentaries on, the *Zakonik Tsara Dushana* (the *Code of Tsar Dushan*). Besides M. Novakovich, as historians within the last quarter of the 19th century the following deserve mention: Panta Sretkovich (for his *Istoriya Scpskoga Naroda*, 3 vols.); Chedomil Miyatovich (*Studies on Old Servian Commerce and Finances*, *Gyuragy Brankovich*, *The Fall of Constantinople*), Stoyan Boshkovich (*Servia under Tsar Dushan*), Lyuba Yovanovich and Lyuba Kovacevich, whose *History of the Servian People* has been adopted as the standard book for the higher schools. Serious scientific work has been done by two young academicians, Dr Yovan Zuyovich (*Geology of Servia*) and Dr M. Tzviyich (*Geographical Researches*, *Caverns of Servia*). The Servians have the reputation of being a poetical nation. Their national ballads—recited by men to the accompaniment of the monotonous sourdine of the *gusle* (a primitive instrument in which the cords are made of horse-tail hairs)—and the lyric impromptus, sung generally by peasant women, have been admired all over the world. Goethe himself translated one or two of the lyric songs into German; and Bowring gave a translation into English, as early as 1828, while in more recent times Owen Meredith freely translated several of them. The national ballads concerning the great battle of Kossovo (15th June 1389), when the Servian independent kingdom was supposed to have been lost, have been translated into English by Mme Miyatovich (London, 1881). The Servian Government bought the copyright of the classical collection of national ballads and songs made by Vuk Stefanovich Karadjich, the father of modern Servian literature, and between 1887 and 1895 published a popular edition of them. Among the modern Servian poets the first place belongs to the prince-bishop of Montenegro, Petar Petrovich Nyegush (d. 1851) with his poem "Gorsky Viyenatz" ("The Mountain's Wreath"), in which the sufferings and heroism of the Montenegrins were sung. Perhaps the best and most melodious lyrical poet is Branko Radicevich (d. 1853); but he is certainly surpassed in depth of thought and versatility of subjects, if not in purity of language and music of rhythm, by Dr Yovan Yovanovich, called "Zmay" (the "Dragon") whose 50 years' jubilee as poet and author was solemnly celebrated by the Servians in 1899. Other poets whom their countrymen hold in high esteem are: Dr Laza Kostich, Gyura Yakshich, Aberdar, Vladimir Vassich, Vladimir Yovanovich, and especially Voislav Ilich. Prince Nicholas of Montenegro has been one of the most popular poets among the Servians during the last quarter of the 19th century.

The Servians have as yet had no great novelist, but have had several excellent writers of short stories. Among them the first place belongs to Dr Laza Lazarevich, several of whose stories have been translated into foreign languages. Yanko Vesselinovich is well known as a writer of stories depicting Servian peasant life. In the same line, M. Vukicevich has also distinguished himself. M. Miyatovich has written some historical novels, which were well received (*Ikoniya, the Vizir's Mother*, *Rayko of Rassina*, &c.). But by far the most popular novelist among Servians is M. Stephen Srematz, whose works, *Ivkova Slava* and *Pop Spira i Pop Tyira*, have won for him amongst his countrymen the title of "the Servian Dickens." In dramatic literature the Servians have been more prolific. This is probably to be ascribed to the fact that a National Theatre, subventioned by the State, has existed at Belgrade for many years. The two best tragedies in the Servian language are considered to be *Meyreemah*, by Mathiya Ban, and *Maxim Tzrnoyevich*, by Dr Laza Kostich, the translator into Servian of Shakespeare's *Romeo and Juliet*. The patriotic drama *Balkanska Tsaritsa*, by Prince Nicholas of Montenegro, has been often played in the Servian theatres, but critics deny to it much dramatic value. The most successful and most productive of modern Servian dramatic authors has been M. Milosh Tsvetich, formerly one of the principal actors at the Belgrade National Theatre. His drama *Stephen Nemanya* and his tragedy *Theodor of Stalac* are ranked among the best Servian dramatic productions.

(C. MI.)

Servo-Bulgarian War of 1885.—The Berlin Congress of 1878, by its revision of the Treaty of San Stephano, created two States in the Balkan Peninsula—the principality of Bulgaria owning a nominal suzerainty to Turkey, and the autonomous province of Eastern Rumelia, presided over by a Turkish governor-general, and apparently intended to remain in close relations with the Porte. Such a settlement, failing to satisfy the conditions, racial or geographical, and being specially distasteful to Russia, could not be expected to secure permanence. National forces, encouraged for a time by Russian influence, quickly brought about a movement in favour of a united Bulgaria, which culminated in September 1885 in a revolution at Philippopolis. Prince Alexander of Bulgaria, recognizing that the movement was irresistible and that unless directed by authority it might degenerate into anarchy and civil war, placed himself at its head, and, proceeding to the Rumelian capital, formally accepted the government of the united Bulgarian states. The standing army of Bulgaria, organized and commanded by Russian officers since the war of 1877–78, consisted of 9 squadrons of cavalry, 12 field batteries of 4 guns, and 8 infantry regiments of 3 battalions, with a reserve, on the German system, filling up the *cadres* to war strength and forming additional units. When fully mobilized the field army numbered about 55,000 men. The Rumelian forces, organized on a militia basis, consisted of 2 squadrons of cavalry, 1 field battery of 4 guns, and 12 battalions, on a peace footing, supplemented by an equal number on mobilization. The total strength amounted to about 35,000 men. Previous to the war, three battalions of Macedonian volunteers and a number of Mahommedans were added to the armed strength at the disposal of Prince Alexander. In the Bulgarian army the whole of the staff and superior officers, as well as about half the regimental captains, were Russians. When the mobilization of the Bulgarian and Rumelian forces was decreed by the Prince, the whole of the Russian officers were at once withdrawn, and the heavy task of creating a staff and selecting young officers for all the superior commands had to be undertaken. As it was assumed that the sultan would intervene to reassert his claim by force of arms, the Bulgaro-Rumelian forces were concentrated as rapidly as possible near the Turkish frontier, the main body between Tirnovo and Jamboli, 4000 men at Philippopolis, and a brigade near Küstendil, facing Macedonia. The railway bridge at Mustapha Pacha was destroyed. Prince Alexander, however, had taken the step of acknowledging the sultan's suzerainty; and the Turks, who had no troops ready to act, gave no sign. A conference of ambassadors met at Constantinople to adjust a situation which was widely misunderstood. The Bulgarians had no intention of submitting to a mandate from the conference not backed by adequate military force, and Turkey was not inclined to begin a war which would probably cause a revolt in Macedonia and might end by rendering Russian influence paramount in Bulgaria. While the conference vainly deliberated, and Great Britain (in 1878 the main supporter of the separation of the two Bulgarias) proved now favourable to their union, the Gordian knot was cut by the announcement that Servia, seeking compensation for the aggrandizement of Bulgaria, had constituted herself the champion of the Treaty of Berlin.

In the latter half of October a concentration of the Servian army on the frontier began, and small Bulgarian forces were moved to Küstendil, Tsaribrod, and Trn. On 14th November, after some minor violations of Bulgarian territory had occurred, King Milan declared war. It was now necessary for the young Bulgarian army, with its newly-appointed staff and superior officers, to counter-march to the west, followed by the Rumelian militia. The Servian army consisted of five divisions, with about 10,000 reserves, making a total of at least 70,000 men. One division was intended to act against Widdin, the rest to converge upon Sofia. A rapid succession of Servian victories were announced; but the Bulgarian troops, about 4500 strong, showed great tenacity and fell back slowly from the frontier. The invaders occupied the Dragoman Pass on 16th November, and Bresnik two days later. The whole question now was whether Prince Alexander would be able to concentrate enough force to stem the invasion at Slivnitza, the only defensible position astride of the Tsaribrod–Sofia road. The position, which was about three miles long, was roughly fortified, the right resting upon the mountains and the weak left being strengthened by lines of trenches bent back. On 17th November the Servians made their first attack against the Bulgarian right and centre, and were repulsed all along the line. Prince Alexander was reinforced in the evening by four Bulgarian battalions and one Rumelian battalion, the latter being sent on from Sofia, two men on each horse of a cavalry regiment. On the morning of 18th November the Servians unsuccessfully attacked the left flank, which was manned by the newly-arrived troops, and later they made a half-hearted advance against the centre. On the following day news arrived that the Servian right column was advancing on Sofia from Bresnik, and Prince Alexander hurried back to the capital to prepare for its defence. The danger was averted by three Bulgarian battalions, which had moved on the evening of the 18th from the left flank of the Slivnitza position in the direction of Bresnik, drove back the Servians, and followed them towards Trn. The prince returned to Slivnitza to find his army everywhere victorious and advancing towards the frontier. On the 22nd the Servians were attacked in front of the Dragoman Pass, which they evacuated, and on the 25th Prince Alexander at Tsaribrod received from King Milan a proposal for an armistice, which was not accepted. The Bulgarian main body, of about 30,000 men, followed by about 15,000, now moved across the frontier towards Pirot, which was occupied on the 26th. On the 27th the Servians attacked, and the Bulgarians evacuated the town: but Prince Alexander, now reinforced by 9000 men, drove the Servians from their positions on the surrounding hills, and was preparing to pursue their shattered forces, when, on the morning of the 28th, the Austrian minister at Belgrade arrived at headquarters and hostilities ceased. The intervention of Austria saved the Servian army, which was greatly demoralized, and was now threatened by the united Bulgarian force of nearly 55,000 men. On the same day the Servians were repulsed with heavy loss in an attack on Widdin, and would have been routed if the hands of the Bulgarians had not been effectually tied.

A more absolutely unjustifiable war than that begun by King Milan can hardly be conceived; but the Bulgarians, though completely victorious, were not permitted to reap the fruits of their success. Their young army, with its improvised staff and newly-appointed field officers, displayed admirable fighting qualities, and the Rumelian militiamen proved themselves to be excellent soldiers. The victory was, however, mainly due to the personal influence, the strenuous exertions, and the sound military judgment of Prince Alexander; and the brief but decisive campaign set the seal to Bulgarian unity. (G. S. C.)

Sestri Ponente, a town of the province of Genoa, Liguria, Italy, 4 miles west of Genoa, on the coast of the Gulf of that name. It has important shipbuilding yards and iron-works, with factories for macaroni, matches, and tobacco, tanneries, and saw-mills, and, in the vicinity, alabaster quarries. The parish church has frescoes by Ansaldo and others. There is a music school. The town is a seaside resort. Population (1881), 10,686; (1899), about 11,000.

Settle, a market-town in the Skipton parliamentary division of Yorkshire, England, on the Ribble, 14 miles north-west of Skipton by rail. The town stands at the foot of the steep limestone rock called Castleberg Cliff, and in the neighbourhood is Victoria Cave, where bones of extinct animals were found. There are an institute, assembly rooms, and a Victoria hall, cotton factories and a tannery. Area of township, 4490 acres. Population (1891), 2253; (1901), 2302.

Setubal, a city of Portugal, district Lisbon, on the right bank of the river Sado, 3 miles above its mouth and 19 miles south-east of Lisbon. It is the third port of the

kingdom, one of the constituents of the port of Lisbon, and the fourth largest town; and an important fishing-station, with some thirty sardine-curing factories. It also makes lace, carries on boat-building, and has factories of fish guano. There is a school of industrial design, and a lyceum. In 1899 the port was entered and cleared by 1161 vessels, of 247,095 tons. In 1898 Setubal possessed 468 fishing-boats, which employed 2131 men and boys; and the fish caught was valued at £41,550 (£90,900 in the combined ports of Setubal, Cezimbra, Sines, and Villa Nova de Milfontes). Marble and porphyry occur in the vicinity. Population (1890), 17,581; (1900), 21,819.

Sevenoaks, a market-town in the Sevenoaks parliamentary division of Kent, England, 22 miles south of London by rail. The neighbourhood contains many country residences. There is an orphanage and a public recreation ground. Knole Park, with its fine trees, is a popular resort. Area, 3273 acres. Population (1881), 6296; (1901), 8103.

Seville, a province of Spain, divided into 13 districts and 100 parishes. Population, 506,812 in 1887, and 547,020 in 1897. Birth-rate, 3·77 per cent.; death-rate, 3·40 per cent.; proportion of illegitimate births, 7·26 per cent. Area, 5429 square miles. Few provinces in Spain have so many railway lines as Seville. After a couple of centuries of decay, the industries increased considerably in the last quarter of the 19th century. The State foundries and manufactures of small-arms, shells, and gunpowder are important and conducted by royal artillery staffs. There are also iron and bronze works, tanneries, breweries, oil and flour-mills, distilleries, manufactures of soap, porcelain, hardware, cotton, linen, woollen, silk stuffs. The exports are valued at £1,000,000 annually, mostly going to England, France, and America. The coasting trade was represented in 1898 by 1700 vessels entered, with 155,500 tons, and 1600 cleared, with 140,000.

More than 2½ millions of acres are well cultivated, and some few districts well irrigated. In 1897 391,830 acres produced wheat, 285,735 acres rye, oats, barley, and maize, 82,038 acres pod fruit, 26,000 acres wine, 477,202 acres olives. There are 89 mines actually worked (6 of alum, 25 copper, 30 iron-ore, 28 coal), and there are 369 registered unproductive mines. The mines that are worked give employment to 1710 hands, and the output in 1898 was 503 tons of alum, 69,849 of copper, 383,864 of iron-ore, 121,074 of coal, and 75,623 tons of agglomerates.

Seville, capital of the above province, on the Guadalquivir. Population (1887), 143,182; (1897), 146,205. The township extends over nearly 30,000 acres. The surrounding country is very fertile and produces abundantly cereals, olive, wine, fruit, and vegetables. Modern embankments have been built on the river, and many other precautions taken by the municipal corporation to prevent floods. Seville is the terminus of three lines that put it into communication with Madrid, and of other lines to Cadiz, Almorchon, Ciudad Real, Huelva, Badajoz, and Lisbon. Three of these lines have branches down to the water-side on the quays, along which vessels of considerable size load and unload. The quay on the left bank is handsome, well paved, 4500 feet long, provided with powerful cranes, and sheds for merchandise. The late duchess of Montpensier gave a part of the grounds of the palace of San Telmo to the municipal corporation, and bequeathed the San Telmo residence to the archbishopric under certain conditions. The navigation up the Guadalquivir from its mouth to Seville is less dangerous for steamers than for sailing vessels, but is still uncertain. Nevertheless, Seville is one of the most important ports in Spain. In 1898, 487 sailing vessels, of which 4 were British and 464 Spanish, and 735 steamers, of which 246 were British and 443 Spanish, entered the port of Seville; and 488 sailing vessels, of which 4 were British and 466 Spanish, and 734 steamers, of which 247 were British and 442 Spanish, cleared. The principal exports in 1898 were iron-ore (381,593 tons, valued at £157,407), copper pyrites, lead and lead ore, corks, oranges, olives and olive oil, wine, and quicksilver. The exports to England in 1898 were valued at £862,366, the imports £162,769; exports to France, £293,200, and imports £75,420; the total exports of the port having been £1,479,529, the imports £486,606. The principal industries are iron, machinery, tobacco, chocolate, soap, porcelain, beer, liqueurs, brandies, corks, and silk in every shape. The royal artillery works and foundries are very important. The ceramic, porcelain and coarse ware manufactory in the ancient Carthusian convent in the *vega* of Triana, on the right bank of the Guadalquivir, is a prosperous industry that employs more than 2000 hands. Equally important is the great tobacco and cigar factory, where 6000 women are employed. At great expense and under careful management, though slowly, repairs of importance have had to be undertaken in the noble cathedral La Giralda; many of the columns had to be attended to urgently, as they were showing signs of decay. Seville is divided into 10 districts, subdivided into 35 *barrios*, with 612 streets, 57 squares. The outer *barrios* are: Los Humeros, La Macarena, San Roque and La Calzada, San Bernardo, La Cesteria, Carreteria, and Bataldlo, Triana, on the right bank of the Guadalquivir, with 50 streets and 15,000 souls, the favourite abode of the gypsies. Public education has progressed in Seville, which has numerous primary state and private schools, an institute, and the university now installed in the Jesuit college founded in the 16th century. The scientific and literary establishments are important. There is a seminary which was formerly the university of Seville.

Sèvres, Deux-, a department of western France, watered by the Sèvre Nantaise and the Sèvre Niortaise.

Area, 2338 square miles. The population, 350,103 in 1881, had decreased to 339,344 in 1901. There were in 1896 895 schools, with 56,000 pupils, the illiterate amounting to 4 per cent. of the population. Out of 1,373,320 acres under cultivation in 1896, 1,047,280 acres were plough-land and 22,230 acres vineyards. The wheat crop of 1899 was valued at £1,120,000; barley, £120,000; oats, £1,204,000; potatoes, £328,000; mangold-wurzel, £220,000; green crop (trefoil, lucerne, and sainfoin), £388,000; hemp, £14,200; vines, £81,000; walnuts, £16,200. Mining in 1898 turned out 18,418 metric tons of coal, but the department produced only 30 tons of steel. Distillation yielded 552,000 gallons of alcohol. Much also is done in refining sugar and in paper manufacture. Niort, the capital, had in 1901 20,962 inhabitants.

Sewage Disposal.—The collection of sewage was fully discussed in the earlier article on SEWERAGE in the 9th edition of this Encyclopædia; it remains to consider the various methods of dealing with it at the outfall in order to render it innocuous. We must, however, have a clear conception of the composition of the liquid to be dealt with, and also know all the circumstances in which it is delivered at the works. Domestic sewage is the fouled water-supply of a community. The water is brought into the household, and after serving its purpose is discharged into the sewerage system as sewage. The composition of this liquid is now fairly well known, and is generally reduced for the purposes of comparison to a standard; that is to say, ordinary sewage is that due to a water-supply of about 30 gallons per head per diem. If the supply is less, and there is no leakage of subsoil water into the drainage system, the sewage will be stronger; conversely, if there is leakage, &c., the sewage will be more dilute, but obviously, the quantity of impurities will, for any given population,

be the same in amount. The subjoined table shows the kind of sewage referred to:—

Average Domestic Sewage, in Grains per Gallon.

Total solids in solution.	Organic carbon.	Organic nitrogen.	Ammonia.	Chlorine.	Suspended.		
					Mineral.	Organic.	Total.
50·54	3·287	1·543	4·70	7·46	16·92	14·36	13·28

For all practical purposes we may say that average sewage contains two tons of suspended matters in each million gallons, one-half of which is mineral matter. When, however, we come to a consideration of trade waste, the question becomes difficult in the extreme, because of the great variety of trades, and the ever varying quantities added to the sewage. Generalizations are of no value in these cases, and each town must be considered on its merits. We may, however, enumerate some of the principal trade wastes; these are from dye-works, print-works, bleach-works, chemical works, tanneries, breweries, paper-makers, woollen-works, silk-works, iron-works, and many others. In some cases one only of these trade wastes finds its way to the sewers; in others, several of them may be found. In some instances, again, these trade wastes are of an alkaline nature, in others they are acid; the mixtures may be either, and of greatly varying character. Next comes the manner in which sewage is discharged at the works. The flow is variable throughout the entire 24 hours, but in the case of sewers discharging domestic sewage only, such sewage being of the standard strength, it will be a close approximation to the facts to say that about two-thirds is discharged between the hours of 7 A.M. and 7 P.M., one-half during during the eight hours of maximum flow, two-fifths during the six hours of maximum flow, and about 7½ per cent. per hour during the two hours of maximum flow. These data will be sufficient for the design of the works intended for dealing with the sewage. Separate calculations must be made if there is trade refuse, or much leakage of subsoil water. In very large systems, again, the maxima are rather less because of the time occupied by the sewage in travelling to the outfall from the more remote parts of the district. Rainfall is generally admitted to the sewers, either wholly or in part. In large cities like London, Glasgow, and many others, one system only is employed for both sewage and rainfall, and it is the best, because of the filthy condition of the street washings where there is much vehicular traffic. In these cases the sewage flow may be increased more than a hundredfold within the space of a few minutes by the occurrence of heavy rainstorms. Of course the sewage disposal works can only deal with a small proportion of such flow, and the balance is discharged into some convenient watercourse, or river, or other suitable place. Even when the separate system is employed, as in the case of the smaller towns, the flow may be increased ten to fifteen times by rain, because it is unusual to carry two sets of drains to the backs of the houses. In designing outfall works, therefore, all these circumstances must be carefully considered. Again, when the sewage is pumped, as is frequently the case, the size of the tanks must often be increased, because in the smaller installations the whole of the day's sewage is frequently pumped out in a few hours; this fact must also be remembered when designing filters.

Nearly every town upon the coast turns its sewage into the sea—a very proper course if the conditions are favourable. That the sea actually has a purifying effect must be obvious to anyone who will take the trouble to follow the sewage after it leaves the outfall. The object to be attained is its dispersion in a large volume of sea-water. As it is lighter than salt water it tends to rise after leaving the sewer; the outfall should, therefore, if practicable, terminate in deep water, so that the two liquids may become well mixed. The currents must be studied by means of floats, and in most cases the sewage must be discharged upon the ebb tide only, and then perhaps not throughout the entire period, the object being to prevent it from being carried towards the shore. That the purification is effected mainly by means of living organisms—with which sea-water teems—is now well established, and it has been urged by competent authorities that this system is not wasteful, since the organic matter forms the food of the lower organisms, which in turn are devoured by fish. Thus the sea is the richer, if the land is the poorer, by the adoption of this cleanly method of disposal. The next step is the partial purification of the sewage by means of a chemical process. When a town lies some distance up an estuary, as for example London, Glasgow, Rochester, and many others, the dilution may be insufficient to prevent a nuisance, or the suspended matters may be deposited upon the foreshore to be uncovered at low water. The first stage of purification is then employed, namely, clarification in tanks. There is some scope for good work here, because badly designed tanks may be costly to work, and may not even then give good results. Practice varies with regard to tank capacity, but as a general rule it should be at least equal to half a day's dry weather flow. This will enable the works manager to turn out a good effluent, even in wet weather, when the volume is much increased. With regard to the practical effect of any particular treatment, it is now recognized that the matters in solution are scarcely touched by any chemical process that can be employed, but the removal of the suspended matter is a great gain, as has been proved in the case of London. Briefly, a good chemical process will do about one-half of the work of purification; and in very many cases it is not necessary to go farther. With regard to the kind of chemical to use, lime, either alone or in conjunction with sulphate of alumina, or with proto-sulphate of iron, is most frequently employed; and its prolonged use is obviously a case of the survival of the fittest. When the resulting sewage sludge has to be filter-pressed, lime is almost essential for the primary treatment of the sewage, in order to destroy the glutinous nature of the sludge. In the case of large towns like London, Manchester, and Salford, the sludge is shipped in specially designed steamers, of 600 tons to 1000 tons burden, and discharged into the sea at a distance from the coast, experience having proved this to be the most economical course to pursue. In the case of towns situated on rivers above the range of tidal waters, the further purification is effected either on land, or by means of artificial filters, or a combination of the two. The question of land treatment is frequently considered from the standpoint of so many persons to the acre; but the best method is to ascertain how many gallons per day an acre of land will purify. As the quality of land varies greatly, the proper volume to be applied per acre can only be ascertained after a good deal of experience. The range lies between about 3000 gallons per acre per day in the case of poor land, to about 30,000 gallons in the same period in the case of the best. Let us assume an instance of the latter kind. The works have been designed on a basis of 1000 persons per acre, producing 30,000 gallons of sewage per day; the land being of a highly suitable character, and the sewage having been clarified, success is assured. But, conversely, through faulty construction of the sewers, the sewage amounts, say, to 60 gallons per head; the land, unable to deal with the liquid, quickly becomes water-logged and offensive, and the works are a failure. Precisely the same remarks apply to artificial filters, which are always designed upon the basis of so

many gallons per square yard of filtering material. Many failures of both land and filters have been due to the fact that the actual sewage flow was greatly in excess of the original estimates. We may say that clay soils lie at one end of the scale, and very porous sands or gravels at the other; obviously, therefore, each case must be considered on its merits. It should be remembered that when such moderate quantities as 3000 gallons per acre per day are applied to land, there is no necessity to remove the suspended matter; broad irrigation being resorted to, the land readily assimilates the solids, and thus one source of expense may be eliminated.

The artificial filters are now generally called bacteria beds; although filters have been in constant use in some cases, as for instance at Wimbledon, for a great number of years. The first filters constructed at these works were made in 1876, and were about 7000 yards in extent. With the growth of population additions have been made of at least five times that area. One of the original beds was used for crude sewage, but the mineral matter choked it completely, and experience pointed to the necessity of clarifying the sewage before filtration. Whether the treatment should be in open or in closed tanks, or whether chemicals should be added, is at present much debated; but seeing that ordinary sewage contains one ton of suspended mineral matter in each million gallons, it is clear that if this is not removed before filtration, it will be retained in the filters and ultimately choke them, as happened at Wimbledon. At the present time the common cesspool is being resuscitated and improved under the name of a septic tank. In this the disintegration of the suspended matter is brought about by anaërobic organisms, and the liquid in passing slowly through the tank absorbs most of the gases due to the breaking down of the organic matter. There is no oxidation at this stage. The liquid is next passed through artificial filters, of which there are many types. What is known as a "contact" filter was constructed, probably for the first time on a large scale, at the London (Barking) works. The object sought to be attained was that of making each cubic yard of filtering material perform the same amount of work, and the least expensive way was apparently to close the outlet, and charge the filter with liquid, allowing it to remain in contact for about two hours, and then drawing it off so that the bed could be thoroughly aërated. No doubt a better way would be to distribute the sewage in the form of a shower of liquid, and work the beds continuously, but this involves a good deal of expense for spreading appliances, and a fall is necessary in the works, which is not always obtainable. Probably the most complete installation of the kind last referred to is that at Salford. Iron pipes are led over the surface of the filters, and spraying nozzles are placed at short intervals, so that the sewage is applied in the form of a heavy shower. But whatever form the filters and appliances may assume, the final result is the same. If the beds are properly aërated, the aërobic organism establishes itself in prodigious numbers, and attacks the organic matter, breaking it down into harmless, soluble, and gaseous products. It is, of course, assumed that the filters are adequate in area, and are properly managed. With regard to the materials to be employed in making sewage filters, it is now well established that the size of the particles has a more important bearing than their composition. At the same time, it may be remarked that materials with very rough surfaces, as for instance coke breeze, are more effective than those with smooth surfaces. Doubtless the former classes afford, in the interstices, a lodging for the bacteria, and no doubt a given quantity of material with rough surfaces will harbour greater numbers than the same amount of smooth.

A reference must be made to the Manchester experiments. The experts' report suggested the provision of 60 acres of filters for dealing with the sewage of the city, which is said to average 30 million gallons per day in dry weather. But after inquiry into the merits of the proposal the officials of the Local Government Board recommended that the filters should be 92 acres in extent, and that the effluent should be finished on land. Storm water filters to take the excess after the sewage was diluted six times were also recommended, such filters being designed to pass 500 gallons per square yard per diem. In this case clarified sewage was to be dealt with on filters 3 feet 4 inches in depth, composed of clinkers broken to pass a sieve with meshes of $1\frac{1}{2}$ inches, but retained on one with meshes of $\frac{1}{8}$ of an inch. It will be observed, therefore, that the bacterial treatment of sewage has scarcely as yet emerged from the experimental stage, but it will certainly be adopted in many cases where it is impracticable to obtain good land in sufficient quantity for the purification of the sewage. With regard to the disposal of sewage-sludge in inland towns, until it has been fairly established by a long trial that bacteria will dispose of this material, the reduction of its bulk by means of filter-presses will be found to be the most satisfactory method of dealing with it. The practical effect is the conversion of 5 tons of offensive mud into 1 ton of hard cake, which may be readily handled and carted. The cost is usually about 2s. 6d. per ton of cake, and a million gallons of average sewage produce about 8 tons. (S. CR.)

Sewing Machines.—The machines and stitches described in vol. xxi. p. 719, of the *Ency. Brit.*, continue in use, and have been supplemented by important inventions for special kinds of work. In sewing carpets the great weights of material make feeding difficult, and therefore machines have been invented that move along the carpet, which itself remains stationary. The earlier forms of this machine were hand-worked. The two lengths of carpet were stretched across the room, and the machine, followed by the operator, who turned it by means of a hand-crank, travelled along the seam. One of these machines was capable of doing the work of eight or ten hand-sewers. The new Singer carpet sewing machine is operated by electricity or other power and runs along a track. The carpet is stretched and sewed so rapidly that one power machine does the work of eight or ten hand machines. A machine for quilting and similar operations has been invented in which two needles produce parallel rows of stitching. The distance of these may be varied by thirty-seconds, from $\frac{1}{16}$ to $\frac{5}{8}$ of an inch. As manufactured by the Singer Company, only one rotating hook is employed beneath the feed-plate to pick up the loops of both threads. Shoes are now sewn by machine, and the introduction of shoe sewing machines has revolutionized the shoe industry. Books are stitched by machine, the Brehmer wire sewing machine and Smyth thread sewing machine being prominent representatives. Button-hole sewing machines are another special type on the production of which years of experiment have been expended. A fast hand operative can produce in ordinary sewing fifty stitches a minute. A foot-driven machine can produce one thousand, and a power-driven machine three to four thousand stitches per minute. For a rate of seven hundred stitches per minute about $\frac{1}{20}$ horse-power is required.

Nearly three million sewing machines are produced annually, in about 150 factories, two-thirds of which are in Germany and the United States. Between 1880 and 1890 from 500,000 to 600,000 sewing machines were made in the United States. The number of factories decreased 50 per cent. in that period, but the same number

of employés were engaged. The labour cost represents 40 per cent. of the cost of a sewing machine. Over $67,000,000 worth of machines was exported from the United States between 1865 and 1895. At present about 150,000 machines are exported annually. (T. O'C. S.)

Sextant.—For astronomical observations on shore, the sextant mounted on a stand, in skilled hands, gives results which are but little inferior to those derived from the portable transit instrument; but in high latitudes the value of the sextant for time observations is somewhat diminished. It possesses the great advantage of being always ready for immediate use; little or no preparation of the ground is necessary, as in the case of the transit instrument. Messrs Troughton and Simm construct the double-frame or pillar form of sextant, while Messrs Cary and Porter adopt the edge-bar principle to secure strength and rigidity of frame. The former is certainly much lighter, but sextants by either maker give equally good results; and when a stand is used, weight is not of much consequence. Accuracy of graduation, small centring error, and superior workmanship can only be assured by makers of repute, and a first-class instrument is indispensable.

Telescopes are of two kinds: the direct, for the more ordinary sorts of observations; and the inverting, for astronomical work, one of the eyepieces of which should be of high magnifying power, not less than 15 diameters. To each eyepiece there are two pairs of wires, each pair perpendicular to the other, and dividing the field of view into nine divisions, of which the central is square. Contacts should be made as nearly as possible in the centre of this square. It is convenient if the telescope is fitted with an interrupted thread to screw into the collar of the up and down piece. *Shades.*—Both mirrors are supplied with coloured shades of different degrees of shade, and may be used either singly or combined for sea observations; they are subject to errors of refraction, due to non-parallelism of the sides of the glass. Coloured eyepieces of neutral glass of different intensities are fitted to slip on and off the conically ground surface of the eyepieces of the telescope; they are used for index error and for observations in the artificial horizon. Introducing no refraction error, they also ensure the suns being of the same brilliancy; a very important point. The up and down piece, when adjusted to equalize the suns, will bring the axis of the telescope nearly exactly in line with the edge of the silvered surface of the horizon glass, which is the best position for observing, and from this it must never be moved until the equal altitude or other observations are complete. *Vernier.*—An extended vernier, *i.e.*, a vernier whose divisions are twice the distance apart of those on the arc, will be found convenient for accurate observing.

Adjustments.—It is essential that the planes of both the index glass and the horizon glass should be perpendicular to the plane of the instrument, and they should also be parallel to one another when the vernier is set to zero. The line of collimation of the telescope must be parallel to the plane of the sextant. This adjustment, though less liable to alter than either of the others, should nevertheless be examined from time to time as follows:—With the sextant mounted on a stand, move the index so as to separate the direct and reflected images of a star by a distance nearly equal to the length of the parallel wires of the telescope, and turn the eyepiece until the direct image of the star coinciding with one extremity of the wire, the reflected image coincides with the other extremity; the wires will then be parallel to the plane of the sextant. Select two bright stars, 120″ or more apart, and make a coincidence of the reflected and direct images on the middle of one wire, and then on the middle of the other. If the two readings agree, the adjustment is correct; if not, the adjusting screws in the collar of the up and down piece must be moved until the coincidence is exact on both wires.

Centring error is a very important error, and is one that cannot be corrected. It may amount in an indifferent instrument to a quantity sufficient to vitiate the result of any observations on one side only of the zenith. It arises from the eccentricity of the centres of the index arm and of the arc, and varies with the angle measured, being generally greater as the angle increases; but the index arm becoming bent, or any part of the frame receiving a blow which alters its shape, the flexure of the instrument from varying temperature, and defective graduation, will all produce errors which it is generally impossible to disentangle, and they are all included in the one correction for centring. This correction is found by comparing the angle measured by the sextant (corrected for index error) with the true angle. The most accurate method, because it employs a large number of observations for the same or nearly the same angle, is by observations of pairs of circum-meridian stars in the artificial horizon at various altitudes. Double the difference between the resulting latitude by each star and the mean latitude will be the centring error for an angle equal to the double altitude of that star, that is, the angle actually measured by the sextant, index error being carefully ascertained and applied before working out. Careful measurement of the angles between stars, compared with their calculated apparent distance, is another method. At Kew Observatory the centring error was determined for certain angles by fixed collimators. Including, as it does, errors from so many causes, the correction does not remain perfectly steady, and it should be ascertained from time to time for any sextant which is to be employed for accurate determination of positions in circumstances which do not permit of the use of methods whereby it as well as other errors are eliminated. In a good sextant the error should not exceed one minute over the whole of the arc.

Sextant Stand.—For observations on shore the sextant should be mounted on a stand, in order to get the best results. In an improved form of stand, the bearing which carries the sextant is square, and the whole bearing revolving on a centre is controlled by a clamp and tangent screw. The counterpoise weights should exactly balance the sextant, and they may be fitted to slide in and out, thus allowing of adjustment.

Levels.—A small spirit-level fixed on one of the arms of the sextant stand, and another level pivoting round the pillar on the index bar of the sextant carrying the microscope, working in a plane parallel to that of the instrument, and fixed by means of a set screw, are of great assistance in placing the sextant exactly in the required position when observing faint stars. With the telescope pointing to the centre of the artificial horizon, the direct and reflected images of the sun at any convenient altitude are made to coincide. The levels are then adjusted and permanently fixed by their set screws. To observe a faint star, it is only necessary to set its double altitude on the sextant, turn the instrument and the stand to bring the bubbles of their respective levels in the centre of their runs, and move the stand until the telescope points to the centre of the artificial horizon and in the direction of the star, when the direct and reflected images will be seen in the field.

Electric Light.—A small electric light fitted on the arm carrying the microscope, and worked by a dry battery, enables the sextant to be read off at night with facility.

Artificial Horizon.—The glass in the roof should be of the best quality, and the faces of each pane accurately parallel. A new form of horizon has been introduced, with the object of diminishing the waves set up in the mercury by vibration. It consists of a shallow rectangular trough of metal gilt. This is amalgamated after getting the surface absolutely clean and free from grease by wetting it with a few drops of dilute sulphuric acid, and rubbing it with a drop of mercury until the whole surface is bright, when a very small quantity of amalgamated mercury added will flow evenly and form a horizontal surface. The dross is wiped off with a broad camel-hair brush. In this shallow trough waves are killed almost instantaneously. The trough should be thoroughly washed on each occasion before being used.

The horizon is placed upon a stand, consisting of two iron plates, the upper resting on the lower, supported by

three long large-headed screws, by means of which it can be levelled. If the stand is raised off the ground a foot or so, on a firm foundation, thus bringing the artificial horizon closer to the telescope, faint stars are more easily observed, and the movement of the sextant necessary to keep the star in the field, owing to its motion in the heavens, will be lessened. A lantern placed on the ground behind, or a little on one side of, the observer, and faintly showing on the artificial horizon, will sufficiently illuminate the wires of the telescope on a dark night.

(A. M. F*.)

Seychelles, an archipelago in the Indian Ocean, consisting of eighty islands—several of them mere islets —situated between 3° 38′ and 5° 45′ S. and 52° 55′ and 53° 50′ E. Of these, Mahé is the largest, most central, and has the greatest height above the sea (2998 feet). Only four others are inhabited, namely, Praslin, La Digue, Denis, and Bird. The islands are surrounded by coral reefs; their soil is most fertile, and the climate, although tropical, is very healthy. Like all the other Indian Ocean islands, the Seychelles have a peculiar fauna, represented by as many as 60 species of plants. The principal exports are cocoa-nut oil, soap, vanilla, tortoise-shell, guano, cocoa-nuts, and cacao. The following statistics show the trade and revenue of the group:—

	1884.	1889.	1894.	1900.
Imports	Rs.4,28,605	Rs.5,70,990	Rs.6,33,061	Rs.9,80,911
Exports	3,92,175	6,53,102	7,64,080	10,36,161
Revenue	1,30,047	2,00,096	2,35,410	3,99,312
Expenditure	...	1,69,083	2,78,470	2,96,920

Population in 1881, 14,081 (7179 males and 6902 females).
„ 1891, 16,440 (8302 „ „ 8138 „).
„ 1901 (estimated), 20,275.

These, as regards religion, consisted in 1891 of 2636 Protestants and 12,608 Roman Catholics, the rest being probably Hindu. In 1900 there were 27 Government schools with a total average attendance of 2037 children. In addition there are St Louis College, with about 100 pupils, and Victoria School with about 80. The rainfall in 1896 was 115·08 inches, considerably above the average fall for the previous five years, which was only 92·83 inches; since 1896 it has varied between 88·42 and 110·75. Temperature, maximum, in shade, 88·7°; minimum, 74·1°. Average temperature for year: maximum, shade, 83·0°; minimum, 76·8°.

Seymour, a city of Jackson county, Indiana, U.S.A. It is on the Baltimore and Ohio South-Western, the Southern Indiana, and the Pittsburg, Cincinnati, Chicago, and St Louis railways, in the southern part of the state, at an altitude of 607 feet. It contains the machinery works of the Baltimore and Ohio South-Western Railroad, and has varied manufactures. Population (1890), 5337; (1900), 6445, of whom 321 were foreign-born and 204 negroes.

Seymour, Horatio (1810–1886), American statesman, was born at Pompey, N.Y., 31st May 1810. His father was prominent in the Democratic party of the state. The son inherited his principles as well as his wealth, and from 1841, when he was first elected to the legislature, to 1854, when he was elected as governor, gradually rose to a commanding position. On national issues he was Conservative, and supported the administration policy of Pierce and Buchanan. In 1860–61 he strongly advocated compromise to avoid secession; but when war developed, he as strongly supported the maintenance of the Union. He remained, however, a Democratic partisan, and vigorously opposed the Administration's policy in respect to emancipation, military arrests, and conscription. In 1862 he was again elected governor of New York. His conduct in dealing with the great Draft Riots of July 1863 drew on him vehement but ill-founded charges of weakness and incompetence. In 1868 the Democratic Convention, while he was its presiding officer, and despite his peremptory refusal, pressed upon him the nomination for President. He reluctantly withdrew his refusal, but in the campaign was overwhelmingly defeated. Afterwards, though frequently urged to enter public life, he lived in retirement on his estate near Utica, where he died 12th February 1886.

Seyne-sur-Mer, La, town, arrondissement of Toulon, department of Var, France, 4 miles south-west of Toulon by rail. The shipbuilding yard now covers nearly 40 acres, has ten slips available for the building of large ships, and with the connected forges gives employment to about 4500 persons. Population (1891), 8836; (1901), 21,002.

Sgambati, Giovanni (1843– ——), distinguished Italian composer, was born in Rome, 28th May 1843, of an Italian father and an English mother. His early education took place at Trevi, in Umbria, and there he wrote some Church music, and obtained experience as a singer and conductor. In 1860 he settled in Rome, and definitely took up the work of winning acceptance for the best German music, which was at that time neglected in Italy. The influence and support of Liszt, who was in Rome from 1861, was naturally of the greatest advantage to him, and concerts of all sorts were undertaken, Sgambati conducting as well as playing the piano. His compositions of this period (1864–65) included a quartet, two piano quintets, an octet, and an overture. He conducted Liszt's *Dante* symphony in 1866, and made the acquaintance of Wagner's music for the first time at Munich, whither he travelled in Liszt's company. His first album of songs appeared in 1870, and his first symphony was played at the Quirinal in 1881; this, as well as a piano concerto, was performed in the course of his first visit to England in 1882; and at his second visit, in 1891, his *Sinfonia epitalamio* was given at the Philharmonic. His most extensive work, a Requiem Mass, was performed in Rome 1901. His many pianoforte works have won permanent success; but his influence on Italian musical taste has been perhaps greater than the merits of his compositions, which, though often poetical and generally effective, are often very thin and slight in style.

Shabatz, a town in Servia, on the right bank of the river Sava. It has a mediæval castle, built in 1470 by Sultan Mahommed II. to facilitate the incursion of the Turks into Croatia and Syrmia, which lie on the left bank of the river. It is the principal market and commercial town of north-western Servia, and exports to Hungary cereals, prunes, cattle, and pigs. It is well known for the excellent white honey which comes from its neighbourhood. The district is rich in lime-trees. Shabatz is the seat of a bishop, of the district prefecture, and of a tribunal. It has a college and a library, and a garrison occupies the old fort. The people of Shabatz have the reputation of being the wittiest people in Servia. Population (1895), 10,917; (1900), 12,072.

Shadrinsk, a district town of Russia, in the government and 383 miles south-east of the town of Perm, on the river Iset. It is a growing town, with several distilleries, and has become an important entrepôt for the export of corn, cattle, hides, skeep skins, woollen cloth, and tallow. Population (1897), 11,686, or 17,050 with the suburbs.

Shahabad, a district of British India, in the Patna division of Bengal. The administrative headquarters are at Arrah. Among other historic sites, it includes the fort of Rohtas, the tomb of Sher Shah at Sasseram, and the battlefield of Buxar.

Area, 4365 square miles. Population (1881), 1,952,647; (1891), 2,063,337. Classified according to religion, Hindus numbered 1,911,372; Mahommedans, 148,439; Christians, 277, of whom only one was a native; "others," 3249. In 1901 the population was 1,963,762, showing a decrease of 5 per cent., compared with an increase of 6 per cent. in the previous decade. The land revenue and rates in 1897–98 were Rs. 19,06,495; number of police, 614; boys at school (1896–97), 23,891, being 16 per cent. of the male population of school-going age; registered death-rate (1897), 35·5 per thousand. The district has been protected against drought by a system of canals from the Sone, some of which are navigable. In 1897–98 the gross receipts from these canals were Rs.12,54,790, and the net receipts Rs.6,36,648, on a total capital expenditure of Rs.2,67,91,549. The district is traversed by the East Indian Railway near the Ganges, and by a branch from Mogulsarai to Gaya, which follows the Grand Trunk Road, and crosses the Sone at Dehri-on-Sone, where are the workshops of the canal.

Shahjahanpur, a city and district of British India, in the Rohilkhand division of the North-Western Provinces. The city is on the left bank of the river Deoha or Garra, 507 feet above the sea; railway junction, 780 miles north-west of Calcutta. Population (1891), 78,522; (1901), 75,662; municipal income (1897–98), Rs.70,953, more than half derived from octroi; incidence of taxation, nearly 9 annas per head; registered death-rate (1897), 30 per thousand. There is a military cantonment. There are manufactures of sugar, but no great trade. There is an American Methodist mission. There are two printing-presses, issuing one vernacular periodical.

The district of SHAHJAHANPUR has an area of 1744 square miles. Population (1881), 856,946; (1891), 918,551, showing an increase of 7 per cent., compared with a decrease of 10 per cent. in the previous nine years; average density, 526 persons per square mile. In 1901 the population was 921,624. The land revenue and rates are Rs.11,08,165, the incidence of assessment being R.1.0.9 per acre; cultivated area (1896–97), 710,831 acres, of which 37,974 were irrigated from wells, &c.; number of police, 2761; vernacular schools, 105, with 4958 pupils; registered death-rate (1897), 43·45 per thousand. The principal crops are rice, wheat, pulse, millet, sugar-cane, and opium. There are no Government canals. The district suffered very severely from the famine of 1877–79. It is now traversed by the Lucknow–Bareilly section of the Oudh and Rohilkhand Railway, with a branch northwards from Shahjahanpur city. At Rosa is a sugar refinery and rum distillery, with an annual out-turn valued at Rs.13,48,000. In 1897–98 the excise duty paid or credited was Rs.6,49,336.

Shahpur, a town and district of British India, in the Rawalpindi division of the Punjab. The town is near the left bank of the river Jhelum. Population (1891), 6337; municipal income (1897–98), Rs.1789. There is an Anglo-vernacular school, and a branch of the Arya Samaj.

The district of SHAHPUR has an area of 4840 square miles. Population (1881), 421,508; (1891), 493,588, showing an increase of 17 per cent., due to the extension of irrigation; average density, 102 persons per square mile. In 1901 the population was 524,572, showing an increase of 6 per cent. The land revenue and rates in 1897–98 were Rs.6,95,949, the incidence of assessment being 5 annas per acre; cultivated area, 401,979 acres, of which 230,417 were irrigated, including 48,637 from Government canals; number of police, 445; number of schools (1896–97), 343, attended by 7551 boys, being 14·2 per cent. of the boys of school-going age; death-rate (1897), 32 per thousand. The principal crops are wheat, millet, pulse, and cotton. The largest town and chief commercial centre is Bhera. The district is traversed from different directions by two branches of the North-Western Railway, which approach each other on opposite banks of the Jhelum; total length, 75 miles; and there are 112 miles of navigable rivers.

Sháhrúd, capital of the Sháhrúd-Bostám province of Persia, situated about 258 miles east of Tehrán, on the high road thence to Mashhad, at an altitude of 4460 feet, in 36° 25′ N. and 54° 59′ E. It has a population of less than 10,000, post and telegraph offices, and a lively transit trade between western Khorassan and Astarábád, the latter place 44 miles away to the north. Although capital of the province, it is not the residence of the governor, who prefers the more salubrious Bostám, a small city with fine gardens and a mosque of the 14th century, lying 3 miles to the north-east.

Shamokin, a borough of Northumberland county, Pennsylvania, U.S.A. It is situated in 40° 47′ N., and 76° 33′ W., on Shamokin creek, east of the centre of the state, at an altitude of 730 feet. Its site is very hilly, but the street plan is fairly regular, and it is divided into ten wards. It has three railways, the Lehigh Valley, the Northern Central, and the Philadelphia and Reading. Lying within the anthracite coal region and surrounded by coal-mines, its chief industries are mining and shipping coal. Its manufactures are mainly of iron and steel. Population (1890), 14,403; (1900), 18,202, of whom 2703 were foreign-born and 65 negroes.

Shanghai, a treaty port in the province of Kiangsu, China. This city is by far the most important of all the treaty ports of China. Its geographical situation gives it peculiar advantages as a centre of trade. It lies midway on the coast line between Canton and Peking, is at the mouth of the great river Yangtse, and is the natural terminus of the ocean-borne trade coming from the Pacific coast of America and from Japan. It is thus the meeting-point of four distinct streams of trade. Its commerce, moreover, is under the protection of all the flags of Europe and America, for all are equally interested. During the Chino-Japanese war, by agreement between Great Britain and Japan, Shanghai and its approaches were specially exempted from the sphere of warlike operations. This is a precedent which will probably be followed in the event of future conflict between China and any foreign Power, while in the event of domestic revolution in China itself, all the foreign Powers would combine to offer the protection of their war vessels. Notwithstanding, therefore, the somewhat unstable condition of the Chinese Government, it would seem that whatever may happen Shanghai may reasonably be deemed safe. The value of the trade passing through the customs grew from H. taels 134,000,000 in 1880 (£36,800,000) to H. taels 306,701,000 (£46,005,000) in 1899—the silver valuation representing more nearly the volume. The principal items of import are cotton yarns (£4,620,700 in 1899), opium (£3,360,700), metals (£933,400), sugar (£907,800), petroleum (£1,185,600), and coal (£686,800); of export, silk (£14,298,300), cotton (£5,378,400), tea (£1,345,500), rice (£1,066,900), hides and skins (£1,043,800), wool, wheat, and beans. Great Britain and the British colonies supply nearly 31 per cent. of the imports, Japan 12½ per cent., and the United States 12 per cent.; and of the exports Great Britain and the British colonies take 18 per cent., the United States 12 per cent., and Japan 10 per cent. In 1900 there entered and cleared 7,982,850 tons of shipping under foreign flag, of which 5,043,700, or rather over 63 per cent., were British. In addition, 1,449,560 tons under the Chinese flag entered and cleared. Shanghai holds with respect to northern and central China the same position in point of trade that Hong Kong holds for south China. Each is the terminus of the ocean steamer traffic and the general depôt whence foreign imports are distributed to the outports, and where native produce is collected for export to foreign countries. The trade of Shanghai thus represents practically the trade of three-fourths of the country. Shanghai, moreover, is not only a port of trade, but is rapidly becoming a large manufacturing and industrial centre. In this category the

first place must be given to cotton mills, which, though not as yet very numerous, give promise of considerable development. The demand in China for cotton yarn, chiefly the produce of the Bombay mills, has been steadily on the increase, and in 1898 the import into Shanghai amounted to 330,000 bales valued at £3,000,000. On the other hand, China produces raw cotton in indefinite quantity, and has hitherto been the main source of supply for the Japanese mills. At the close of 1898 there were running in all 300,000 spindles—five out of eight mills being in foreign hands, the others being native. Cloth weaving was tried in two of the mills, but abandoned in favour of spinning. Next in importance is the reeling of silk cocoons by machinery. This is gradually supplanting the wasteful method of native reeling, giving a much better finished and consequently more valuable article. Shanghai also contains three large establishments for docking, repairing, and building ships. Among minor industries are match factories, rice and paper mills, ice, cigarette, piano, carriage, and furniture factories, wood carving, &c.

By virtue of extra-territorial clauses in the various treaties, all foreigners, subjects of any treaty Power, are exempted from the jurisdiction of the Chinese authorities, and made justiciable only before their own officials. As there are now fourteen treaty Powers represented at Shanghai, there are consequently fourteen distinct courts sitting side by side, each administering the law of its own nationality. In addition, there is also a Chinese court, commonly called the Mixed Court, though it is no more mixed than any of the others in an international sense, except that a foreign assessor sits with the Chinese judge in cases where any of his own nationality are interested as plaintiffs. At first sight this arrangement seems somewhat complicated, but the principle is simple enough, viz., that a defendant must always be sued in the court of his own nationality. In criminal cases there is of course no difficulty. For the British, English law alone prevails, and they can only be tried and punished in the British court. In the same way Frenchmen can only be tried in the French court, and so on for every nationality. In civil cases, where both parties are of the same nationality, there is also no difficulty, *e.g.*, for British subjects the British court is the forum, for German subjects it is the German court. In cases involving cross actions with mutual accounts, say between an Englishman and a German, the case may be brought into either the British or the German court according as the initiative is taken by the German or the Englishman. If the German constitutes himself plaintiff he must sue his opponent before the British court, and *vice versâ*. The greatest anomaly, however, in respect of the government of Shanghai is the local municipal control. This is exercised by the foreign community as a whole without regard to nationality, and is a share of the power which properly belonged to the Chinese local authorities, but which by convention or usage they have allowed to fall into foreign hands. It is exercised only within the area termed the foreign settlements, which were originally nothing more than the "area set apart for the residence of foreign merchants." Of these "settlements" there were and are still only three—the British acquired in 1845, the French acquired in 1849, and the American acquired in 1862. At an early date, as a foreign town began to spring up, the necessity of having some authority to lay out and pave streets, to build drains, &c., for the common benefit, became evident, and as the Chinese authorities shirked the work and the expense, the foreigners resolved to tax themselves voluntarily, and appointed a Committee of Works to see the money properly laid out. In 1854 the consuls of Great Britain, France, and the United States drew up a joint code of regulations applicable to both the then settlements, British and French, which being ratified by the respective Governments became binding on their respective subjects. The two areas thus became an international settlement, and the subjects of all three nationalities—the only Powers then interested—acquired the same privileges and became liable to the same burdens. The code thus settled was acquiesced in by the Chinese authorities and by other nationalities as they came in, and it conferred on the foreign community local self-government, practically free from official control of any description. In 1863 the area covered by the regulations was extended by the addition of the American settlement, which meanwhile had been obtained by that Government from the Chinese. But about the same time, 1862, the French decided to withdraw from the joint arrangement, and promulgated a set of municipal regulations of their own applicable to the French area. These regulations differed from those applicable to the joint settlement, in that a general supervision over municipal affairs was vested in the French consul-general, his approval being made necessary to all votes, resolutions, &c., of the ratepayers before they could be enforced at law. Since the above date there have, consequently, been two municipalities at Shanghai, the French and the amalgamated British and American settlements, to which the original regulations continued to apply. The area of the latter has been very greatly extended within the last few years, and now amounts to some nine or ten square miles. The regulations have been altered and amended from time to time, and they have been accepted expressly or impliedly by all the treaty Powers which have since come into the field. The settlements have thus lost their original character of British or American, and become entirely cosmopolitan. The consuls of all the treaty Powers rank equally, and claim to have an equal voice in municipal affairs with the British or American consuls.

The powers of self-government thus conferred on the foreign community consist in exclusive police control within the area, in draining, lighting, maintenance of streets and roads, making and enforcement of sanitary regulations, control of markets, dairies, and so forth. To meet these expenses the foreign ratepayers are authorized to levy taxes on land and houses, to levy wharfage dues on goods landed or shipped, and to charge licence fees. Taxes are payable by every one living within the settlements, Chinese included, though the latter have no voice in the local administration. The executive is entrusted to a municipal council of nine, elected annually from among the general body of foreign ratepayers, irrespective of nationality. The legislative function is exercised by all ratepayers possessing a certain pecuniary qualification in public meeting assembled. Proxies for absentee landlords are allowed. One such public meeting must be held annually to pass the budget and fix the taxation for the year. No official sanction is required, and no veto is allowed for such money votes. Special meetings may be held at any time for special purposes. New legislation of a general kind requires to be approved by all the treaty Powers in order to be binding on their several nationalities, but within certain limits the ratepayers can pass by-laws which do not require such sanction. In 1899 the revenue of the municipality amounted to taels 916,000 (£137,400). The French municipality is worked on similar lines, except that every vote and every disbursement of money is subject to the approval of the French consul-general. The executive council consists of eight members, four of whom must be French and four may be foreign. The French consul-general is chairman *ex officio*, so that the control in any case is French and practically official.

Both settlements were originally intended for the residence of foreign merchants only, but as the advantages of living under foreign protection became evident by reason of the security it gave from arbitrary taxation and arrest, Chinese began to flock in. This movement has continued, and is now particularly noticeable in the cases of retired officials, many of whom have made Shanghai their home. The total native population in the settlements by the census of 1895 was 286,753, and the estimated population of the native city was 125,000, making a total for all Shanghai of 411,753. In 1900 the foreign population was 6774, of whom 2691 were British. The magnitude of the foreign interests invested in Shanghai may be gathered from the following rough summary:—Assessed value of land in settlements registered as foreign-owned £5,500,000; docks, wharves, and other industrial public companies—market value of stock, £2,250,000; private property estimated £1,500,000,—total £9,250,000. This is exclusive of banks, shipping and insurance companies, and other institutions which draw profits from other places besides Shanghai. (G. J.)

Shanhai-Kwan, a garrison town in the extreme north-east of the province of Chihli, China. It is situated at the point where the range of hills carrying the Great Wall of China dips to the sea, leaving a *kwan* or pass of limited extent between China proper and the provinces of Manchuria. It is thus an important military station, and the thoroughfare of trade between Manchuria and the great plain of China. The Imperial Northern Railway from Tientsin and Taku, 174 miles from the former, runs through the pass, and continues skirting the northern shore of the Gulf of Pechili as far as the treaty port of Newchwang, where it is in touch with the Russian system of railways leading from Port Arthur to the Siberian main line. The pass forms the southern limit of the Russian sphere of influence as defined in the convention between Great Britain and Russia of April 28, 1899.

Shanklin, an urban district (1894), and watering-place, Hampshire, England, in the Isle of Wight, 8 miles south-east of Newport by rail. The pier was completed

in 1891, and in 1892 a lift connecting the town and esplanade was constructed at a cost of £6000. A Home of Rest for seventy-three inmates (women) was erected in 1893. Shanklin Chine is a picturesque chasm in a lofty cliff bordering the bay on which the town stands. Population (1891), 3921; (1901), 4533.

Shan Tribes. See Lolos.

Shari, an important river of North Central Africa, carrying the drainage of a large area of the interior into Lake Chad (*q.v.*). It has a considerable number of head-streams, which take their rise on the watersheds between the Lake Chad basin and those of the Nile and Congo. The most important is probably the Bamingi, one branch of which, the Kukuru, rises in about 7° N. and 21° 15′ E. At about 90 miles from its source the Bamingi is some 80 yards wide and 12 feet deep, with a gentle current, and is navigable from this point to Lake Chad. Flowing generally north-west, it receives the Gribingi on the left bank in 8° 42′ N., the Bahr Sara (probably derived from a distant source in the south-west, and thought by some to be the principal branch of the river) in 9° 20′, and the Bangoran on the right in 9° 14′ N. The Gribingi is a narrow and tortuous river with rocky banks, and often broken by rapids, though navigable at high water to 7° N. It flows in great part through a forest-clad country. The Bangoran rises in about 7° 45′ N. and 22° E., in a range of hills which separates the countries of Dar Runga and Dar Banda, and, like the Bamingi, flows through open or bush-covered plains with isolated granite ridges. Below the junction the Shari becomes a large river, reaching, in places, a width of over 4 miles in the rains; while its valley, bordered by elevated tree-clad banks, contains many temporary lakes and back-waters. Its waters abound with hippopotami and crocodiles, and the country on either side with game of all kinds. In 9° 46′ N. it receives the Bakare or Awauk from the east, known in its upper course as the Aukadebbe. This, like the Bahr es Salamat, which enters the Shari in 10° 2′ N., traverses a wide extent of arid country in southern Wadai, and brings no large amount of water to the Shari. In 10° 12′ a divergent branch, the Ergig, leaves the main stream, only to rejoin it in 11° 30′. In 12° 15′ the Shari receives on the west bank its largest tributary, the Logone, the upper branches of which rise far to the south between 6° and 7°. In 9° 15′ N. it has a width of over 500 yards. Its system is said to be connected with that of the Benue (see Niger) by means of the Tuburi Swamp, but this is somewhat doubtful. Below the Logone the Shari, here a noble stream, soon splits up into various arms, forming an alluvial delta, flooded at high water, before entering Lake Chad. The whole upper basin of the Shari, as well as the right bank of the lower river, falls within French territory, and a steamer was placed on its waters in 1897 by the French pioneer Gentil.

Sharon, a borough of Mercer county, Pennsylvania, U.S.A. It is situated on the Lake Shore and Michigan Southern and the Pennsylvania railways, in the north-western part of the state, at an altitude of 855 feet. It has extensive iron and steel works, including blast furnaces, rolling mills, foundries, and nail factories. Population (1890), 7459; (1900), 8916, of whom 1805 were foreign-born and 113 negroes.

Sharpsburg, a borough of Allegheny county, Pennsylvania, U.S.A. It is on the river Allegheny, and on the Pennsylvania and the Pittsburg and Western railways, in the south-western part of the state, at an altitude of 741 feet. Its industries are coal mining and iron manufacturing, and it has blast furnaces, rolling mills, and foundries. Population (1890), 4898; (1900), 6842, of whom 1280 were foreign-born and 258 negroes.

Shasi, a city in the province of Hupeh in China, on the left bank of the river Yangtse, about 85 miles below Ichang. It was opened to foreign trade under the Japanese treaty of 1895. The town lies below the summer level of the Yangtse, from which it is protected by a strong embankment running for many miles above and below. Its value consists in the fact that it is the terminus of an extensive network of canals which run through the whole of the low country lying on the north bank of the Yangtse as far down as Hankow. Native boats, as a rule, prefer the canal route to the turbulent waters of the Yangtse, their cargoes being transhipped at Shasi across the embankment into river boats. The population is estimated at 80,000. Foreign residents are very few, and the trade passing through the maritime customs is comparatively insignificant, amounting in 1900 to only £85,600. The place is, however, a large distributing centre for native trade, and is besides the seat of an extensive manufacture of native cotton cloth.

Shatsk, a district town of Russia, in the government and 88 miles north of the town of Tamboff. It is a growing prairie town, with a considerable export trade in grain and flour. Population (1897), 13,928.

Shaw, Henry Wheeler (1818–1885), American humorist, known by his *nom de guerre* of "Josh Billings," was born at Lanesborough, Mass., 21st April 1818, his father being a well-known member of the Massachusetts Legislature and of Congress. After knocking about in the West for a time, Shaw, in 1858, settled down in Poughkeepsie, New York, as a land-agent, and began writing newspaper articles; but it was not till he hit upon the idea of adopting a system of facetious mis-spelling that he made a success in 1860 with his "Essa on the Muel, bi Josh Billings," in a New York paper. He proceeded to work this vein of humour in a number of droll articles and volumes, which had a widespread circulation, the principal being: *Josh Billings, his Sayings* (1866), *Josh Billings's Farmers' Almanax* (1870), *Josh Billings's Complete Works* (1877), *Josh Billings's Spice-Box* (1881). He also became very popular as a platform lecturer, his mannerisms and apparently unstudied witticisms making him a conspicuous contemporary "character." He died at Monterey, California, 14th October 1885. His *Life* was published by F. S. Smith in 1883.

Shaw, Richard Norman (1831– ——), British architect, was born in Edinburgh, 7th May 1831. At the age of sixteen he went to London and became a pupil of William Burn. It was in Burn's office that he formed the friendship with William Eden Nesfield which so profoundly influenced the careers of both. There Mr Shaw was thoroughly grounded in the science of planning and in the classical vernacular of the period. This office-work was supplemented by attendance at the architectural schools of the Royal Academy, and the careful study of old and of the best contemporary buildings. In 1854, having finished his term of apprenticeship with Burn, he gained the gold medal and travelling studentship of the Royal Academy, and from then until 1856 he travelled on the Continent, studying and drawing old work. On his return in 1856 he was requested by the Council of the Royal Academy to publish his drawings. This work, entitled *Architectural Sketches from the Continent*, was issued in 1858. In the meantime Nesfield was continuing his studies with Anthony Salvin; Mr Shaw also entered his office, and remained there until 1857, when he widened his experience by working for

three years under George Edmund Street. In 1863, after sixteen years of severe training, he began to practise. For a short time he and Nesfield joined forces, but their lines soon diverged. Mr Shaw's first work of importance was Leyes Wood, in Surrey, a building of much originality, which was followed shortly afterwards by Cragside, for Lord Armstrong, begun in 1869. These buildings, and others taken in hand at about the same period, attracted immediate attention; and from that time until he retired from active practice his works followed one another in quick succession. In 1872 Mr Shaw was elected an Associate of the Royal Academy, and a full member in 1877; he joined the "retired" list towards the end of 1901.

Other characteristic examples of Shaw's work are Preen Manor, Shropshire; New Zealand Chambers, Leadenhall Street; Pierrepont, Wispers, and Merrist Wood, in Surrey; Lowther Lodge, Kensington; Adcote, in Shropshire; his houses at Kensington, Chelsea, and at Hampstead; Flete House, Devonshire; Greenham Lodge, Berkshire; Dawpool, in Cheshire; Bryanstone, in Dorsetshire; Chesters, Northumberland; New Scotland Yard, on the Thames Embankment; besides several fine works in Liverpool and the neighbourhood. He also built and restored several churches, the best known of which are St John's Church, Leeds; St Margaret's, Ilkley; and All Saints', Leek. His early buildings were most picturesque, and contrasted completely with the current work of the time. The use of "half timber" and hanging tiles, the projecting gables and massive chimneys, and the cunningly contrived bays and recessed fireplaces, together with the complete freedom from the conventions and trammels of "style," not only appealed to the artist, but gained at once a place in public estimation. Judged in the light of his later work, some of those early buildings appear almost too full of feature and design; they show, however, very clearly that Mr Shaw, in discarding "academic style," was not drifting rudderless on a sea of fancy. His buildings, although entirely free from archæological pedantry, were the outcome of much enthusiastic and intelligent study of old examples, and were based directly on old methods and traditions; but although naturally they took more or less traditional forms, the architect concerned himself more with the spirit of old work than with its letter, and within these wide limits he allowed his imagination full play. As his powers developed, his buildings gained in dignity, and had an air of serenity and a quiet homely charm which were less conspicuous in his earlier works; the "half timber" was more sparingly used, and finally disappeared entirely. His work throughout is especially distinguished by treatment of scheme. There is nothing tentative or hesitating. His planning is invariably fine and full of ingenuity. Adcote (a beautiful drawing of which hangs in the Diploma Gallery at Burlington House) is perhaps the best example of the series of his country houses built between 1870 and 1880. The exterior is simple and dignified, and the detail refined and elegant. The elements are few but perfectly proportioned and combined, and the scale throughout is consistent. The Great Hall is the keynote of the plan, and is properly but not unduly emphasized. The grouping of the rooms round the Hall is very ably managed—each room is in its right position, and has its proper aspect. The plan is a practical one, fulfilling its purpose as a modern house, but is nevertheless full of originality and character. New Zealand Chambers, in Leadenhall Street, another work of about the same period (1870–80), is a valuable example of Mr Shaw's versatility. Here he employed a completely different method of expression from any of his preceding works, in all of which there is a trace of "Gothic" feeling. This is a façade only of two storeys, divided by piers of brickwork into three equal spaces, filled by shaped bays rich with modelled plaster; above, drawing the whole composition together, is a finely enriched plaster cove. An attic storey, roofed with three gables, completes the building, which is the antithesis of the accepted type of city offices; it is yet perfectly adapted to modern uses. New Scotland Yard is undoubtedly Mr Shaw's finest and most complete work. The plain granite base is not only subtly suggestive of the purposes of the building, but by dividing the height with a strongly marked line, gives a greater apparent width to the structure; it suggests also a division of departments. By its mass, too, it prevents the eye from dwelling on the necessary irregularity of the lower windows, which are not only different in character from those of the upper storeys, but more numerous and quite irregularly spaced. The projecting angle turrets are most happily conceived, and besides giving emphasis to the corners, form the main point of interest in the composition of the river front. The chimneys are not allowed to cut the sky-line in all directions, but have been drawn together into massive blocks, and contribute much to the general air of dignity and strength for which this building is remarkable. Simple roofs of ample span complete a composition conspicuous for its breadth and unity.

Mr Shaw's influence on his generation can only be adequately gauged by a comparison of current work with that which was in vogue when he began his career. The works of Pugin, Scott, and others, and the architectural literature of the time, had turned the thoughts both of architects and the public towards a "revived Gothic." Before he entered the field, this teaching had hardened into a creed. Mr Shaw was not content to hold so limited a view, and with characteristic courage threw over these artificial barriers and struck out a line of his own. The rapidity with which he conceived and created new types, and as it were set a new fashion in building, compelled admiration for his genius, and swelled the ranks of his adherents. It is largely owing to him that there is now a distinct tendency to approach architecture as the art of Building rather than as the art of Designing, and the study of old work as one of methods and expressions which are for all time, rather than as a means of learning a language of forms proper only to their period.

Sheba. See ARABIA.

Sheboygan, a city of Wisconsin, U.S.A., capital of Sheboygan county. It is on the shore of Lake Michigan, at the mouth of the river Sheboygan, and on the Chicago and North-Western Railway, in the western part of the state, at an altitude of 589 feet. The city is regularly laid out, is divided into eight wards, has a good water-supply from the lake, and is well sewered. Its harbour is excellent, and it has a large lake commerce, principally in lumber. The manufactures consist mainly in the making of furniture, especially chairs, for which it is noted. The city was settled in 1836, incorporated as a village in 1846, and received its city charter in 1853. Population (1890), 16,359; (1900), 22,962, of whom 7399 were foreign-born.

Shechem, now NABLUS, the chief town of a sanjak of the Beirût vilayet of Asiatic Turkey, altitude 1870 feet, situated in Central Palestine, in the valley which separates Ebal from Gerizim. There are Protestant and Roman Catholic missions, with churches and schools, and a Samaritan synagogue. The population of 24,000 includes 170 Samaritans, 700 Christians, and a few Jews.

Sheep. See AGRICULTURE.

Sheerness, a garrison town and naval seaport of England, at the extreme north-west corner of the Isle of Sheppey, Kent, and on the right bank of the Medway estuary, 51 miles east of London by rail and 11 miles east-north-east of Chatham. Blue Town, the older part of the town, with the dockyard, is defended by strong modern-built fortifications, especially the forts of Garrison Point and Barton's Point. The dockyard, chiefly used for naval repairs, covers about 60 acres, and consists of three basins and five docks, the depth of water on the sill ranging from 15 to 25½ feet. Within the yard there are extensive naval stores and barracks for 1000 men. Outside the dockyard are the residence of the port admiral and admiral of the Nore and military barracks. The harbour is spacious, sheltered, and deep even at low water. The place is also visited to some extent for sea-bathing. There is steamboat connexion between Sheerness and Port Victoria, on the opposite side of the Medway; with Southend, on the opposite side of the Thames; and with Chatham and London Bridge. Queenborough Pier, 1 mile to the south, is the port of embarkation for passengers travelling to the Continent *viâ* Flushing. It was in this neighbourhood that the celebrated mutiny of the Nore broke out in 1797, the Nore being the name given to the estuary of the Thames between the Isle of Sheppey and the opposite coast of Essex. The Nore light floats above a sandbank 4 miles north-east of Sheerness. Before 1894 Sheerness formed part of the parish of Minster, but it was then formed into a separate parish. Area, 876 acres. Population (1891), 14,492; (1901), 18,273.

Sheffield, a city (1893), and a county (1888) and parliamentary borough of Yorkshire, England, at the confluence of the Sheaf with the Don, 39 miles south of Leeds, 157 miles by rail north-north-west of London. Of its constituent townships Upper Hallam still remains in large part agricultural. In 1897 the title of lord mayor was conferred on the chief magistrate, and under an Act of 1900 the city area was extended by 4003 acres. The water-works, supplying about 8½ million gallons daily to the city and district, were acquired by the corporation in 1887. New water-works are in course of construction in the Little Don valley, while Sheffield is also a constituent of the Derwent Valley Water Board (1899). The capital cost of the water-works undertaking up to 25th March 1900 exceeded £2,571,374. The electric lighting of the borough, dating from 1892, was in 1898 transferred to the corporation. From 1884 to 1886 a new sewage system, costing £132,000, and sewage disposal works, costing £44,000, were executed. Tramways, mostly electric traction, in 1900 stretched altogether over 17½ miles length of streets. Further, in 1900, 13 miles of new tramway line were sanctioned, involving in most cases the widening of the roads passed through, and an estimated expenditure of £349,495. A number of old streets have been pulled down, many narrow streets widened, new and handsome thoroughfares opened up. A handsome carriage bridge connects the districts of Walkley and Neepsend. At Newhall (Attercliffe) a single-span bridge, 46 feet 6 inches between parapets, has taken the place of the former one, only 12 feet 6 inches wide. At Carbrook a new carriage bridge displaces a wooden pedestrian structure. On 25th March 1900 the streets of Sheffield had a total length of 321·58 miles. The street improvements determined on in 1900 involved an estimated cost of £445,176. Besides the parish church of St Paul's there are 35 churches and numerous dissenting places of worship. Ransmoor Church was rebuilt in 1888 at a cost of £22,000. University College, constituted by that title in 1897, was founded in 1879 as the Firth College, enlarged in 1892, and comprises, besides the college, a technical department (1886), occupying the buildings of the former grammar school, and equipped with metallurgical laboratories, steel works, iron foundry, a machine and fitting shop, &c.; and a medical school (1888), together with a school of pharmacy (1885). Other modern buildings include a new town-hall (1897), costing, exclusive of the site, about £130,000; the Mappin art gallery (1887); the Ruskin museum, since 1890 in the custody of the corporation, and transferred to Meersbrook Park; Jubilee memorial (1887); Lodge Moor hospital (1888); the Lyceum (1893), Alhambra, and other theatres. Since 1899 the markets, purchased from the duke of Norfolk for £526,000, have been the property of the corporation. Several new parks and recreation grounds have been opened in recent years. Cutlery still continues the leading industry of Sheffield. Minor industries include important horse-hair cloth, railway-carriage fittings, and testing works. The Cutlers' Company (1624) of Sheffield, by Acts 1883–88, exercises jurisdiction, in all matters relating to the registration of trade marks, over all goods composed in whole or in part of any metal, wrought or unwrought, as also over all persons carrying on business in Hallamshire and within 6 miles thereof. The collieries include the Nunnery, with four drawing pits, and the Aldwarke main, with machinery to raise 1500 tons daily. In 1891, 3385 persons were engaged in the making of machinery; 22,115 men and 3642 women in the manufacture of cutlery, files, saws, &c.; and 2476 persons in mining. There are three daily newspapers. Area of municipal (coextensive with parliamentary) borough, 19,651 acres. Population (1891), 324,243; (1901), 380,717.

Shelbyville, a city of Indiana, U.S.A., capital of Shelby county. It is on the river Big Blue, and the Pittsburg, Cincinnati, Chicago, and St Louis and the Cleveland, Cincinnati, Chicago and St Louis railways, in the central part of the state, at an altitude of 768 feet. It is in an agricultural and coal-mining region and contains varied manufactures. Population (1890), 5451; (1900) 7169, 326 being foreign-born and 257 negroes.

Shenandoah, a borough of Schuylkill county, Pennsylvania, U.S.A. It is situated in 40° 49′ N. and 76° 12′ W., in the valley of Shenandoah creek, on the Pennsylvania, the Lehigh Valley, and the Philadelphia and Reading railways, in the eastern part of the state, at an altitude of 1249 feet. Its site is hilly and uneven, the street plan is irregular, and it is divided into five wards. It is within the anthracite coal-field, several large collieries being within its limits, and others surrounding it. Its industries relate almost exclusively to mining, handling and shipping coal. Population (1890), 15,944; (1900), 20,321, of whom 8499 were foreign-born.

Shepton Mallet, a market-town in the Eastern parliamentary division of Somersetshire, England, 5 miles east-south-east of Wells by rail. The hospital and the Masonic hall have been enlarged. Urban district offices, including rooms for technical instruction, have been built. Area of civil parish (an urban district), 3825 acres. Population (1891), 5267; (1901), 5238.

Sher Ali Khan (1825–1879), Amir of Afghanistan, was born in 1825, and was one of the younger sons of the Amir Dost Mahommed, whom he succeeded in 1863. For some time after his succession Afghanistan was in a state of anarchy, and his rebellious half-brothers overran the country while he remained at Kandahar mourning the loss of a favourite son. At length, however, the capture of Kabul in 1867 roused him to action; but in spite of his own bravery he suffered general defeat until 1868, when he regained Kabul. Supported by the viceroys of India, Lord Lawrence and Lord Mayo, Sher Ali remained on good terms with the British Government for some years; but after the rebellion of his son Yakub Khan, 1870–74, he leaned towards Russia, and welcomed a Russian mission at Kabul in 1878, and at the same time refused to receive a British mission. This led to long negotiations, and ultimately to war, when the British forced the Khaibar Pass in November 1878, and defeated the Amir's forces on every occasion. Sher Ali fled from his capital, and taking refuge in Turkestan, died at Mazar-i-Sharif 21st February 1879.

Sherbrooke, a city and port of entry of Quebec, Canada, and capital of Sherbrooke county, 80 miles east of Montreal, at the confluence of the rivers Magog and St Francis, and on the Grand Trunk, Canadian Pacific, Quebec Central and Boston and Maine railways. It is the seat of a Roman Catholic bishop and the district courts, and contains manufactories of woollen and cotton goods and machinery, also saw- and grist-mills. Population (1891), 10,110; (1901), 11,765.

Sherbrooke, Robert Lowe, Viscount (1811–1892), British statesman, was born on 4th December 1811, at Bingham, Notts, where his father was the rector. He was educated at Winchester and University College, Oxford, where he took a first class in classics and a second in mathematics, besides taking a leading part in the Union debates. In 1835 he won a fellowship at Magdalen, but vacated it on marrying, in 1836, Miss Georgina Orred (*d.* 1884). He was for a few years a successful "coach" at Oxford, but in 1838 was bitterly disappointed at not being elected to the professorship of Greek at

Glasgow. In 1841 Lowe moved to London, to read for the Bar ("called" 1842); but his eyesight showed signs of serious weakness, and, acting on medical advice, he determined to try his fortune in the colonies rather than in London. He went to Sydney, where he set to work in the law courts. In 1843 he was nominated by Sir George Gipps, the governor, to a seat in the New South Wales Legislative Council; owing to a difference with Gipps, he resigned his seat, but was elected shortly afterwards for Sydney. Lowe soon made his mark in the political world by his clever speeches, particularly on finance and education; and besides obtaining a large legal practice, he was one of the principal writers for the *Atlas* newspaper. In 1850 he went back to England, in order to enter political life there. His previous University reputation and connexions, combined with his colonial experience, stood him in good stead. *The Times* was glad to employ his ready pen, and as one of its ablest leader-writers he made his influence widely felt. In 1852 he was returned to Parliament for Kidderminster in the Liberal interest. In the House of Commons his acute reasoning made a considerable impression, and under successive Liberal ministries (1853–1858) he obtained official experience as secretary of the Board of Control and vice-president of the Board of Trade. In 1859 he went to the Education Office as vice-president of the Council in Lord Palmerston's ministry; there he pursued a vigorous policy, insisting on the necessity of payment by results, and bringing in the revised code (1862), which embodied this principle and made an examination in "the three R's" the test for grants of public money. He felt then, and still more after the Reform Act of 1866, that "we must educate our masters,"[1] and he rather scandalized his old University friends by the stress he laid on physical science as opposed to classical studies. Considerable opposition was aroused by the new régime at the Education Office, and in 1864 Lowe was driven to resign by an adverse vote in Parliament with reference to the way in which inspectors' reports were "edited." Lord Palmerston's death in October 1865 was followed by the formation of the Russell-Gladstone ministry and the introduction of the Reform Bill of 1866. Lowe, a Liberal of the school of Canning and Peel, had already made known his objections to the advance of "democracy,"—notably in his speech in 1865 on Sir E. Baines's Borough Franchise Bill,—and he was not invited to join the new ministry. He retired into what Bright called the "Cave of Adullam," and opposed the Bill in a series of brilliant speeches, which raised his reputation as an orator to its highest point and effectually caused the downfall of the Government. He remained, nevertheless, a Liberal; and after the franchise question had been settled by what Lowe considered Disraeli's betrayal, and he had been elected the first member for London University, he accepted office again in the Gladstone Cabinet of 1868 as chancellor of the Exchequer. Lowe was a rather cut-and-dry economist, who prided himself that during his four years of office he took twelve millions off taxation; but later opinion has hardly accepted his removal of the shilling registration duty on corn (1869) as good statesmanship, and his failures are remembered rather than his successes. His proposed tax of a halfpenny a box on lucifer matches in 1871 (for which he suggested the epigram *ex luce lucellum*) roused a storm of opposition, and had to be dropped. In 1873 he was transferred to the Home Office, but in 1874 the Government resigned.

[1] This phrase is always ascribed to Lowe, and has become history in association with him. But what he really said in his address to the Edinburgh Philosophical Institution in 1867, was that it was necessary "to induce our future masters to learn their letters."

When the Liberals returned to power in 1880 he was raised to the peerage as Viscount Sherbrooke, but from 1875 till his death at Warlingham, Surrey, on 27th July 1892, his health was constantly failing, and by degrees he figured less and less in public life. Bobby Lowe, as he was popularly known, was one of the most remarkable personalities of his day, with his tall, striking figure, albino complexion and hair, and faculty for epigram and irony. During the 'seventies the following epitaph was suggested for him by one of the wits of his day:—

> Here lies poor old Robert Lowe;
> Where he's gone to I don't know;
> If to the realms of peace and love,
> Farewell to happiness above;
> If, haply, to some lower level,
> We can't congratulate the devil.

Lowe was delighted with this, and promptly translated it into Latin, as follows:—

> Continentur hac in fossa
> Humilis Roberti ossa;
> Si ad cœlum evolabit
> Pax in cœlo non restabit;
> Sin in inferis jacebit
> Diabolum ejus pœnitebit.

His literary talent, though mainly employed in journalism, was also shown in a little volume of verses, *Poems of a Life* (1884). He married a second time, in 1885, but left no children.

See also *Life and Letters*, by A. PATCHETT MARTIN. Longmans, 1893. (H. CH.)

Shereef Pasha (1818–1887), Egyptian statesman, born in 1818, was a Circassian who filled numerous administrative posts under Said and Ismail Pashas. He was of better education than most of his contemporaries, and had married a daughter of Colonel Sèves, the French non-commissioned officer who became Soliman Pasha under Mehemet Ali. As minister of foreign affairs he was useful to Ismail, who used his bluff *bonhomie* to veil many of his most insidious proposals. Of singularly lazy disposition, he yet possessed considerable tact—he was in fact an Egyptian Lord Melbourne, whose policy was to leave everything alone. His favourite argument against any reform was to appeal to the Pyramids as an immutable proof of the solidity of Egypt financially and politically. His fatal optimism rendered him largely responsible for the collapse of Egyptian credit which brought about the fall of Ismail. Upon the military insurrection of September 1881, Shereef was summoned by the Khedive Tewfik to form a new ministry. The impossibility of reconciling the financial requirements of the national party with the demands of the British and French controllers of the public debt, compelled him to resign in the following February. After the suppression of the Arabi rebellion he was again installed in office by Tewfik, but in January 1884 he resigned rather than carry out the policy of the evacuation of the Sudan. He died at Gratz, 20th April 1887, on his way to take the waters at Carlsbad.

Sheridan, Philip Henry (1831–1888), American soldier, third son of John and Mary (Minor) Sheridan, was born at Albany, New York, 6th March 1831. In 1832 his father removed to Somerset, Perry county, Ohio. His early education was acquired in the primitive common school of that early day; his later at West Point, at which he graduated in 1853 as number thirty-four in a class of fifty-two. He was commissioned, July 1853, brevet second lieutenant. From 1853 to 1861 he served on the frontier and the Pacific coast, engaged in Indian war-

fare. He was appointed captain, 13th Infantry, 14th May 1861, having passed through the intermediate grades—second lieutenant, 22nd November 1854, and first lieutenant, 1st March 1861. After serving as president of a board to audit claims, and as quartermaster and commissary, Sheridan was commissioned colonel, 2nd Michigan Cavalry, 25th May, and engaged in a raid on Booneville, Miss., and in pursuit of the enemy from Corinth to Baldwin, Miss. He was in command of a cavalry brigade, 11th June, and participated in skirmishes at Booneville, Blackland, Donaldson Cross Roads, and Baldwin, and in the engagement at Booneville, 1st July, where he won his first star, being made brigadier-general of volunteers, 1st July 1862. He was engaged with Faulkner's command, 27th August, and was in command of "Pea Ridge Brigade," 6th September. He was then placed in command of infantry troops, 1st October to 2nd November, the 11th Division of the Army of the Ohio, and took part in Buell's advance in Kentucky, being heavily engaged at the battle of Perryville, Ky., 8th October. He marched to the relief of Nashville, Tenn., October to November, in command of the 3rd Division, Right Wing, 14th Army Corps, later designated the 3rd Division of the 20th Army Corps, Army of the Cumberland. His division rendered efficient service in the battle of Stone River, 31st December 1862 to 3rd January 1863, where he won his double stars, being commissioned major-general of volunteers, 31st December 1862. He took part in the pursuit of Van Dorn to Columbia, Tenn., in March 1863, capturing a train and prisoners near Eagleville; in the advance on Tullahoma, 24th June to 4th July, capturing Winchester, 27th June; in the campaign across Cumberland mountains and the river Tennessee, 15th August to 4th September; engaged in the battle of Chickamauga, 19th and 20th September; was active in operations in and about Chattanooga from September to December 1863; and was engaged in the battle of Missionary Ridge, 23rd to 25th November, where his troops were the first to reach the crest of the ridge and to break the enemy's line. From December 1863 to March 1864 he was engaged in the occupation of East Tennessee. He was then placed in command of cavalry once more, and was at the head of the Cavalry Corps of the Army of the Potomac from 4th April to 3rd August in the Richmond campaign. He took part in the battles of the Wilderness, 5th and 6th May; Todd Tavern, 7th May; Spottsylvania Court House, 8th May; and Cold Harbor, 31st May and 1st June. He engaged in a raid to Haxall's Landing and the return, 9th to 24th May, destroying parts of the Virginia Central and Richmond and Fredericksburg railways; and in the Charlottesville raid, 7th to 28th June. Then again he was transferred to infantry troops, and placed in command of the army of the Shenandoah, 4th to 7th August, and of the Middle Military Division, 7th August 1864 to 25th March 1865. He fought the battle of Opequan, 19th September, defeating Early; and was made brigadier-general in the regular army, 20th September 1864. He again defeated Early at Fisher's Hill, 22nd September. He fought the battle of Cedar Creek, 19th October, in which he turned a disastrous defeat into a great victory, for which he received the thanks of Congress and his commission as major-general U.S. Army, 8th November 1864. He undertook a raid from Winchester to Petersburg, 27th February to 24th March 1865, in which the James River and Kanawha Canal was greatly injured, and the Richmond and Fredericksburg, Virginia Central, and Gordonsville and Lynchburg railways were cut in several places. He was next engaged in the Richmond campaign, 25th March to 9th April 1865, where his services in a large measure hastened the final ending of the war, being in command at the battles of Five Forks, 1st April; Sailor's Creek, 6th April; and Appomattox Station, 8th April. From 3rd June 1865 to 5th September 1867 General Sheridan commanded successively, with headquarters in New Orleans, the Military Division of the South-West, the Military Division of the Gulf, the Department of the Gulf, and the Fifth Military District (Louisiana and Texas). From 12th September 1867 to 16th March 1869 he was in command of the Department of the Missouri, and was engaged in the winter campaign of 1868–69 against the Indians, resulting in their defeat and surrender. He was commissioned lieutenant-general U.S. Army, 4th March 1869; from 16th March 1869 to 1st November 1883 was in command of the Division of the Missouri; and from 1st November 1883 to 5th August 1888 was in command of the armies of the United States, headquarters Washington; commissioned general U.S. Army, 1st June 1888. He died at Nonquit, Mass., 5th August 1888, aged fifty-eight years.

GENERAL PHILIP SHERIDAN.
(From a photograph by Sarony, New York.)

In person General Sheridan was 5 feet 5 inches high, of compact frame, with large round head. On horseback he appeared of ordinary height, owing to his body being relatively longer than his lower limbs. As a soldier he never knew what fear was; he was cool, active, resolute, and resourceful, with every watchful care for the welfare of his troops. Fighting was his element, and to be in the thick of the fray was his greatest enjoyment. He was one of the great cavalry leaders of the world. He was president of the Society of Army of the Potomac and of the Society of Army of the Cumberland, the latter for fourteen years, and was noted as a presiding officer for despatching business by prompt military methods. In manner he was modest and unassuming. He married, 3rd June 1875, in Chicago, Miss Irene Rucker, daughter of General D. H. Rucker, of the regular army. He spent the summer of 1870 in Europe, and was the guest of the king of Prussia during the Franco-German war. He wrote his *Personal Memoirs*, 2 vols., published after his death. (H. M. C.)

Sherman, a city of Texas, U.S.A., capital of Grayson county. It is in the north-eastern part of the state, at an altitude of 720 feet, and is chiefly a railway centre, being entered by six railways, the Houston and Texas Central, the Missouri, Kansas, and Texas, the St Louis South-Western, the Gulf, Colorado, and Santa Fé, the St Louis, and San Francisco, and the Texas and Pacific, all important lines. The surrounding country produces cotton, wheat, and corn, for which Sherman is the chief shipping-point. It contains cotton gins, cotton seed oil mills, and other manufacturing establishments. Austin College, situated here, had, in 1899, 8 instructors and 108 students. Population (1890), 7335; (1900), 10,243, of whom 308 were foreign-born and 2131 negroes.

Sherman, John (1823–1900), American financier and statesman, a younger brother of General W. T. Sherman (see below), was born at Lancaster, Ohio, in 1823. He began the study of law at Mansfield, Ohio, and was admitted to the Bar in 1844. For ten years he practised his profession with success, and with only casual interest in politics. His associations and predilections were with the Whigs, and he was a delegate to the National Convention that nominated General Taylor in 1848. Upon the repeal of the Missouri Compromise in 1854, he joined the great popular movement in Ohio against this policy, and was elected to Congress in the autumn of that year as an "Anti-Nebraska" man. In the summer of the next year he took an active part in the formal organization of the Republican party in the state, and at the opening of Congress in December began a long career of public service. As a member of the House, 1855–61, he quickly manifested the qualities which characterized his whole political life. Though a thorough and avowed partisan, he was within the party the counsellor of moderate rather than extreme measures, and thus gained on the whole a position of great influence. He was a member of the committee sent by the House in 1856 to investigate the troubles in Kansas, and drafted the report of the majority. In 1859 he was the Republican candidate for Speaker of the House, but was obliged, after a contest that lasted two months, to withdraw, largely because of the recommendation he had inadvertently given to a virulent anti-slavery book. He became, however, chairman of the Committee on Ways and Means, and was instrumental in the enactment of the Morrill Tariff Act of 1860. In March 1861 he took his seat in the Senate, to which he had been elected to succeed Salmon P. Chase, when the latter became secretary of the Treasury. As senator he sat continuously till he became secretary of the Treasury in 1877. His interest and efficiency in financial legislation in the House led to his appointment on the Senate Committee of Finance, and after 1867 he was chairman of this influential committee. He thus became associated with the enactment of all the great fiscal laws through which the strain of war and of reconstruction was sustained. He gave earnest support to the Legal Tender Act, and the substitution of the national for the state banking system. When, after the end of the war, the question of financial readjustment came up, he vigorously opposed Secretary McCulloch's policy of retiring the legal tenders, and urged a different plan for effecting the resumption of specie payments. On the questions relating to political reconstruction and the policy of President Johnson, he supported his party, though opposed to its Radical leaders. He warmly advocated the insertion in the Reconstruction Acts of a provision ensuring the early termination of military government; and he opposed the impeachment of President Johnson, though he voted for conviction on the trial. During the administrations of President Grant his leadership in shaping financial policy became generally recognized. The Resumption Act of 1875, which provided for the return of specie payments four years later, was largely his work both in inception and in formulation, and his appointment to the Treasury Department by President Hayes in 1877 enabled him to carry the policy embodied in the law to successful execution. His administration of the department, in circumstances of great difficulty arising out of the "greenback" agitation and the adverse political complexion of Congress, won him high distinction as a financier.

At the end of the Hayes Administration he was again elected to the Senate from Ohio, and held his seat till 1897. During this period he was largely concerned in the enactment of the Anti-Trust Law of 1890, and of the so-called Sherman Act of the same year, providing for the purchase of silver and the issuing of Treasury notes based upon it. This latter Act he approved only as a means of escaping the free coinage of silver, and he supported its repeal in 1893. In 1880 and 1888 he aspired actively to the Republican nomination for the Presidency, but failed to obtain the requisite support in the Convention. Upon the accession of President McKinley, in 1897, he resigned from the Senate and became secretary of State; but under the tension of the war with Spain the duties of the office became too exacting for his strength at his age, and in April 1898 he resigned and withdrew into private life. Infirmities multiplied upon him, until death came at Washington 22nd October 1900. (W. A. D.)

Sherman, William Tecumseh (1820–1891), American general, was born 8th February 1820, at Lancaster, Ohio. He was descended from Edmond Sherman, who emigrated from England to the Massachusetts Bay Colony in 1634. His father moved from Norwalk, Conn., to Lancaster, Ohio, in 1810, became a judge of the Supreme Court of Ohio, and died suddenly in 1829, leaving his widow with a family of young children. William was adopted by the Hon. Thomas Ewing, a close friend of the father, sometime a senator of the United States and a member of the national cabinet. When sixteen years of age he was appointed a cadet in the United States Military Academy at West Point. He graduated in 1840, near the head of his class, and was made a lieutenant of artillery. His first field service was in Florida against the Seminole Indians. The usual changes of station and detached duty made him acquainted with the geography of all the Southern states, and Sherman improved the opportunity to make topographical studies, which became of distinct value to him later. When the war with Mexico began in 1846, he was stationed at Fort Moultrie, in Charleston Harbour, South Carolina. He asked for field duty, and was ordered to join an expedition going to California by sea. He was made adjutant-general to Colonel Mason, military governor, and as such was executive officer in the administration of local government, till peace came in the autumn of 1848 and the province was ceded to the United States. In 1849 he was sent home with despatches. In 1850 he married Miss Ewing. In 1853 he resigned from the army, and went back to California to conduct at San Francisco a branch of an important St Louis banking-house. He continued successfully in the management of this business through a financial crisis incident to a wildly speculative time, until in the spring of 1857 the house by his advice withdrew from Californian affairs. In 1859 the state of Louisiana established a military college, and Sherman became its superintendent, including in his duties the

professorship of engineering. In the spring of 1860, when it was evident that Louisiana would join the states seceding from the Union, he resigned the superintendency of the college and returned to St Louis, parting with the governor of the state and his colleagues in the school with regret and mutual esteem. Though his brother, John Sherman, the distinguished statesman, was a leader in the party which had elected Mr Lincoln, William Sherman was very conservative on the slavery question, and his distress at what he thought an unnecessary rupture between the states was extreme. Yet his devotion to the national constitution was unbounded, and he offered his services as soon as volunteers for the three-years' enlistments were called out. On 14th May 1861 he was appointed colonel of the 13th Infantry, a new regiment in the regular army, and was soon assigned to command a brigade in General McDowell's army in front of Washington. He served with it in the battle of Bull Run, 21st July, was promoted brigadier-general of volunteers, and, with his friend and classmate General Thomas, was in August sent to Kentucky to serve under General Robert Anderson. In October Anderson's health failed, and Sherman succeeded him in command of the department, coming eventually under General Halleck, who with General Buell divided the departments of the Mississippi valley. After the capture of Fort Donelson (1862), Sherman, with a division of new troops, joined Grant's expedition up the river Tennessee. At the battle of Shiloh Sherman's gallant conduct gained him promotion to major-general. His appreciation of Grant, and his sympathy with the chagrin he suffered after this battle, cemented the friendship between the two. In the campaign against Corinth, Miss., Halleck commanded in person; but in July 1862 he was made general-in-chief, and Grant resumed the command of the army of the Tennessee, with Sherman as senior subordinate. During the operations against Vicksburg, aiming at possession of the lower Mississippi valley, Sherman made expeditions to Chickasaw Bayou, near Vicksburg, and to Arkansas Post, on the Red river, and then joined Grant's main army again, becoming commander of the Fifteenth Army Corps. After Vicksburg surrendered, on 4th July 1863, Grant was made commander of all the forces west of the Allegheny mountains, and Sherman became the head of the army of the Tennessee, which consisted of three corps. To relieve the army of the Cumberland after the battle of Chickamauga, Grant and Sherman moved to Chattanooga, and in a series of brilliant victories (November and December) defeated the Confederates, under Bragg and Longstreet, again liberated East Tennessee, and opened the way for an aggressive campaign southwards. To complete the preparation for this, Sherman made a winter expedition from Vicksburg into the heart of Mississippi as far as Meridian, destroying railways and making impracticable for a season the transfer of military operations to that region. When Grant became general-in-chief of all the armies of the United States (March 1864), Sherman was made commander of the military division of the Mississippi, including his army of the Tennessee, now under McPherson, the army of the Cumberland, now under Thomas, and the army of the Ohio, under Schofield. Making detachments for garrisons and minor operations in a theatre of war over 500 miles wide, he assembled, near Chattanooga, his three armies, aggregating a hundred thousand men, and began (1st May 1864) the campaign of Atlanta, in the state of Georgia. The country was mostly forest-clad, the roads mere waggon-tracks, his line of communications a single railway, his base 400 miles away. Owing to the character of the country, both sides resorted to entrenched camps covered by formidable entanglements of felled trees, and to movements by the flank, avoiding direct attacks on the enemy's front. Atlanta was taken on 1st September. The Confederate General Hood, who had superseded Johnston, began early in October a vigorous movement on Sherman's communications, designed to carry the war back into Tennessee. After a devious chase of a month, Hood moved across Alabama to northern Mississippi. Sherman divided his army, leaving Generals Thomas and Schofield to meet Hood, and with sixty thousand men abandoned his base and marched 300 miles across Georgia to the sea. Savannah, on the Atlantic coast, was taken, railways were destroyed, and the Confederate Government was severed from its western states. In January 1865 Sherman marched northwards again, once more abandoning his base, and aiming for Richmond, the Confederate capital, near which the armies of Grant and Lee were waging a war of giants. Every mile of his march northwards through the Carolinas diminished the supply region of the enemy, and desperate efforts were made to stop his advance. General Johnston was recalled to active service, and showed his well-known skill, but his forces were inadequate. Sherman defeated him and reached Raleigh, the capital of North Carolina, on 13th April, having marched nearly 500 miles from Savannah. Lee's position in Virginia was now desperate. Thomas and Schofield, in Tennessee, had routed Hood's army, and Schofield had been transferred to the North Carolina coast (a movement of about 2000 miles by land and sea) and was now united again to Sherman, who had come into co-operation with Grant. Lee broke away from Petersburg, 3rd April, but was overtaken, and surrendered to Grant on the 9th. Johnston's surrender to Sherman soon followed, and the war was ended. When Grant became President in 1869, Sherman succeeded him as general-in-chief, and the remainder of his active service was spent in the administration of the army in peace. He died at New York, 14th February 1891.

GENERAL W. T. SHERMAN.

(From a photograph by Sarony, New York.)

Shetland, a county of Scotland composed of a group of islands and rocks lying north-east of Orkney, the shortest distance between the two groups being 50 miles, if Fair Isle, which lies between them and belongs to Shetland, be excluded. About 20 of the islands are inhabited, and 70 others are used for grazing.

Area and Population.—The area of the county (foreshore excluded) is 362,615 acres, or about 566 square miles. The population was in 1881, 29,705; in 1891, 28,711; in 1901, 28,185, of whom 12,430 were males and 15,755 were females. Taking the land area only (352,889 acres, or 551·4 square miles), the number of persons to the square mile in 1901 was 51, and the number of acres to the person 12·5. The population decreased between 1881 and 1891 by 3·4 per cent., and between 1891 and 1901 by 1·8 per cent. Between 1881 and 1891 the excess of births over deaths was 1901, and the decrease of the resident population 994. The following table gives particulars of births, deaths, and marriages in 1880, 1890, and 1899 :—

Year.	Deaths.	Marriages.	Births.	Percentage of Illegitimates.
1880	500	111	671	5·9
1890	477	130	605	2·97
1899	432	128	597	3·0

The following table gives the birth-rate, death-rate, and marriage-rate per thousand of the population for a series of years :—

	1880.	1881–90.	1890.	1891–98.	1899.
Birth-rate . .	22·48	22·19	21·01	20·23	21.42
Death-rate . .	16·75	16·40	16·57	15.59	15.53
Marriage-rate .	3·72	4·98	5·15	4.34	4·24

There were 67 Gaelic-speaking persons in the county in 1891, and 27 foreigners. Valuation in 1889–90, £49,273; 1899–1900, £46,680.

Administration.—Shetland unites with Orkney to return a member to Parliament. Lerwick (4061), the county town, is the only police burgh. There are 12 civil parishes, with a combination poorhouse at Lerwick; the number of paupers and dependents in September 1899 was 999. Shetland forms a sheriffdom with Orkney and Caithness, and there is a resident sheriff-substitute at Lerwick.

Education.—Twelve school boards manage 61 schools, which had in 1898–99 an average attendance of 3450, and 3 voluntary schools (2 Church and 1 Episcopal) had 163. Lerwick has a secondary school, and 2 other schools in 1898 earned grants for giving higher education. The "residue" grant is spent on swimming and navigation classes.

Agriculture.—In 1898 the percentage of cultivated land was 16·5. Of 3550 holdings in 1895 the average size was 16 acres. The percentage under 5 acres was 20·00, between 5 and 50 acres 77·44, and over 50 acres only 2·56. There were 710 crofts under 5 acres, 2391 between 5 and 20 acres; 50 holdings between 50 and 100, 32 between 100 and 300, and 9 above 300, 3 being over 1000 acres. Crofting agriculture is still primitive, tillage being done with the spade to a large extent, and seaweed being the principal manure applied to the exhausted ground. Little progress has been made, notwithstanding considerable reductions of rent. From the commencement of the operations of the Crofters' Commission in 1886 down to the end of 1898, 2496 applications to fix a fair rent had been dealt with by the Commissioners, and rents amounting to £11,203 reduced to £8015, while arrears of £13,438 had been cancelled to the extent of £9512. Of applications to enlarge holdings 217 had been dealt with and 936 acres added to existing crofts. The following table gives the principal acreages at intervals of five years from 1885 :—

Year.	Area under Crops.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1885	58,538	10,415	4622	1045	42,673	783
1890	59,548	9,532	5028	1085	43,094	809
1895	57,673	9,342	4997	1090	41,764	480
1899	59,687	9,327	4929	1245	43,717	469

The following table gives particulars of the live stock during the same years; the "horses" are Shetland ponies :—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or Calf.	Sheep.	Pigs.
1885	5,605	22,377	8465	84,727	3497
1890	4,803	18,876	8020	98,320	3129
1895	5,503	18,883	7768	102,098	2901
1899	5,863	18,859	7994	110,795	2301

In 1891, 1984 men and 606 women were returned as being engaged in agriculture. There is no wood in the county.

Industries.—Though the knitting of fine shawls and other articles with the wool of the native sheep is the distinctive industry, fishing is the mainstay of the greater part of the population, the men being generally both crofters and fishermen. There are 52 stations in the Shetland fishery district, some statistics about which are given in the subjoined table :—

Year.	Boats.			Value of Gear.	Resident Fishermen and Boys.	Total Value of all Fish.
	No.	Tons.	Value.			
1890	865	5195	£28,286	£29,455	2884	£89,504
1898	789	7504	£38,459	£26,311	3043	£134,237
1899	807	8045	£43,707	£27,827	3059	£263,888

Of the total value of fish in 1899, £234,766 was the value of herrings only. The total number of persons engaged in the district in 1899 in various branches of the sea fisheries was 8294. The industrial population in 1891 numbered 1602 men and 5318 women, of whom 4862 were engaged in the manufacture of textiles.

Communication with the mainland and between the islands is noticed under Lerwick.

Shields, North. See TYNEMOUTH.

Shields, South, a seaport, county, municipal and parliamentary borough, and railway station, Durham, England, in the Jarrow parliamentary division of the county, on the south bank of the Tyne, at its mouth, with stations on the North-Eastern Railway. The Tyne dock has a water area of 50 acres, the tidal basin of 10 acres, and the quays and yards cover about 300 acres. In 1895 the construction of a new deep-water entrance was completed. Police buildings, erected at a cost of £22,000, were opened in 1893. Population (1891), 78,391; (1901), 97,267.

Shigatsé. See TIBET.

Shikarpur, a town and district of British India, in the Sind province of Bombay. The town is about 18 miles from the right bank of the Indus; railway station 23 miles north-west of Sukkur. Population (1891), 41,991; (1901), 49,491. Shikarpur has always been an important place, as commanding the trade route through the Bolan Pass. The administrative headquarters of the district have been transferred to Sukkur, where the North-Western Railway crosses the Indus. It has a large market and manufactures of carpets, cotton cloth, and pottery. There is a high school and also two printing-presses, issuing two commercial gazettes and a vernacular newspaper.

The district of SHIKARPUR has an area of 9296 square miles. Population (1891), 915,497; (1901), 1,018,237, showing an increase

of about 11 per cent. in each decade. Land revenue (1897–98), Rs.36,13,037, the incidence of assessment being Rs.3.3.11 per acre; cultivated area, 1,084,603 acres, of which 829,945 were irrigated from Government canals; number of police, 1059; children at school, 28,294, being 2·9 per cent. of the population; death-rate (1897), 31·21 per thousand. The principal crops are wheat, millet, pulse, and oil-seeds. Both portions of the district are traversed by the main line of the North-Western Railway for 170 miles, with 22 stations, and the branch to Quetta runs from Ruk junction for 40 miles past Shikarpur town. Agriculture entirely depends upon canals from the Indus, and the river occasionally causes disastrous floods.

Shildon, a parish, urban district, and market-town of Durham, England, in the Bishop Auckland parliamentary division of the county, 9 miles west from Darlington by rail. At New Shildon (or East Thickley), a neighbouring village, are extensive railway engine and waggon works belonging to the North-Eastern Railway Company. The population of the urban district (Shildon and East Thickley) was in 1891, 9537; in 1901, 11,759.

Shillong, a town of British India, in the Khasi Hills district of Assam, of which province it is the capital. It is situated in 25° 32′ N. and 91° 55′ E., on a plateau 4978 feet above the sea, 64 miles by cart-road south of Gauhati, on the Brahmaputra. Population (1881), 3640; (1899), 6720; municipal income (1896–97), Rs.41,276; death-rate (1891), 24·26 per thousand. Shillong practically dates from 1864, when the district headquarters were transferred from Cherrapunji. It was chosen as the seat of government in 1874, when the province of Assam was constituted. Every one of the public buildings and houses that quickly grew up was levelled to the ground by the great earthquake of 12th June 1897. Cantonments are provided for a battalion of Gurkhas, 789 strong in 1898, with two guns, and it is the headquarters of a company of volunteers. There is a Government high school, with 155 pupils in 1896–97, and a training school for masters. The school for European children has been discontinued, but will be re-established by the Government. There are three printing-presses, one of which issues two monthly periodicals in the Khasi language.

Shiloh, a name applied to a locality in Hardin county, Tennessee, U.S.A., about an old meeting-house called Shiloh church. The place has become famous as the scene of one of the fiercest battles of the Civil War. It is situated in the southern part of the state, about two miles west of Pittsburg Landing, on the Tennessee river, and occupies a plateau about half a mile long and 80 feet above the river. On this ground, in April 1862, the Union forces, under General Grant, and the Confederates under Generals Johnston and Beauregard, fought fiercely for two days. The Confederates, who knew that General Buell was on his way to join Grant, determined to destroy the army of the latter, if possible, before his arrival. The attack was unexpected by the Union troops, and the first day's fighting resulted in driving them in disorder to the bluff at Pittsburg Landing, leaving a considerable number of guns and prisoners in the hands of the enemy. During the night, however, Grant was reinforced by Buell's and Lew Wallace's forces, which gave him about 50,000 fighting men, half of whom were fresh troops. To oppose them the Confederates had only about 30,000. General Johnston had fallen in the first day's fight, and Beauregard was now in command. The Confederates, after a stubborn resistance, lost all the ground gained the first day and were forced back to Corinth, Mississippi, which place they soon afterwards destroyed and evacuated. More than 100,000 men were engaged in this battle, and the losses on both sides were enormous, sometimes estimated as high as 22,000 men. This is sometimes called the battle of Pittsburg Landing.

SHIP.

I. History and Statistics.

Before steam was applied to the propulsion of ships, the voyage from Great Britain to America usually took some weeks; at the beginning of the 20th century the time was about six days. Similarly, the voyage to Australia, which took about thirteen weeks, was reduced to about thirty days, although it cannot be said that exceptionally fast vessels are employed in this service. The fastest of the sailing tea-clippers required about three months to bring the early teas from China to Great Britain; they are now brought to London by the ordinary P. and O. service in six weeks. In further illustration of the progress made, it may be mentioned that there are Atlantic liners now running between England and America which maintain a speed of 23 knots over the whole course, as compared with the 12 or 15 knots of a few years ago. The accommodation in the passenger ships above referred to is quite palatial compared with that in the corresponding wooden sailing ships of a date fifty or sixty years earlier, and the fare provided does not differ greatly from the best that can be obtained on shore.

The changes from sail power to steam power for propulsion, and from wood to iron and steel for constructional purposes, proceeded together, though at first very slowly. Knowledge of the theory of steam and the steam engine was slowly acquired; and for many years mechanical engineering as an art failed altogether to keep pace with theory. Thus the marine steam engine was at first a very imperfect motor, and the services upon which steamships could be used to advantage were, in consequence, much restricted. There was, moreover, a national prejudice against steamships of any kind. Our fathers saw, with regret, the possibility and probability that the sailing ships upon which they prided themselves, and which had arrived after many years, even centuries, at something like perfection, might pass out of existence altogether. A similar prejudice existed against the substitution of iron for wood in shipbuilding. As regards warships, "the Wooden Walls of Old England," by which England had to a considerable extent achieved her greatness, were held almost in veneration, and it was with profound regret that they were at last admitted to belong to the past.

Iron and steel construction.

It is recorded that an iron boat, intended apparently for passenger service, was built and launched on the river Foss, in Yorkshire, in 1777, and shortly afterwards iron was used for the shell plating of lighters for canal service. One of these, having its shell constructed of plates five-sixteenths of an inch thick, was built near Birmingham in 1787. About the same time parts of wooden ships began to be replaced by iron, partly, no doubt, with the view of increasing the strength of the structure, but also because of the increasing difficulty of obtaining suitable shipbuilding timber in sufficient quantities for the requirements of the day. The first iron strengthenings thus introduced were beam knees; early in the 19th century, iron "diagonal riders" for providing the longitudinal strength were introduced by

Sir Robert Seppings, and from this period down to the present day iron strengthenings for resisting both transverse and longitudinal strains have been generally used in wooden ships. The introduction of iron as a recognized material for ship construction is usually given as dating from 1818, when the lighter *Vulcan* was built on the Monkland canal, near Glasgow.

The advantages of the new material were admitted for service on canals, where there was no risk of grounding on a dangerous bottom, but they were not so readily admitted for river service, and still less for coasting and sea voyages. Among the early objections to the use of iron were: (1) from its weight it could not be expected to float, and was therefore unsuitable for the construction of a floating body; (2) when a ship constructed of this material grounded and was exposed to bumping on a shore, the bottom would be easily perforated; (3) the bottom could not be preserved from fouling by weeds and barnacles; and (4) the iron affected the compass, making it untrustworthy, if not useless. Gradually, however, the material made its way, and the objections to it proved to be for the most part untenable. Objection (1), although often repeated, was proved to involve a fallacy. With regard to objection (2), it was found that iron ships might ground and be subjected to a great deal of bumping and rough usage without being destroyed, and that, on the whole, they were better off in this respect than wooden ships. On more than one occasion when iron and wooden ships were stranded together by the same gale and in approximately the same circumstances, the iron ships were got off and, apart from local injury, were found to be little the worse for the grounding, while the wooden ships were either totally wrecked, or, if got off, were strained to such an extent as to be ruined. The power of resistance of iron ships to the strains produced by grounding received, in 1846–47, a remarkable confirmation in connexion with the grounding of the *Great Britain*, the first large screw steamer built of iron. This ship had been initiated by, and was built under the supervision of, Mr I. K. Brunel, who had bestowed much attention upon the details of her construction. In 1846 she ran ashore in Dundrum Bay, in Ireland, and settled on two detached rocks; and although she remained aground for eleven months, including a whole winter, she was subsequently got off and repaired, and afterwards did good service. As regards the fouling of the bottom, this evil, although not preventible, can be lessened materially by frequent cleaning and repainting, provided, of course, that docks are available. The fourth objection, the effect of iron on the compass, was a matter of very serious moment, and the attention of one of the leading scientific men of the day (Sir G. B. Airy) became directed to it. After experimenting with the *Rainbow* at Deptford and the *Ironsides* at Liverpool, Sir G. B. Airy in 1839 read a paper on the subject before the Royal Society, and the rules which he gave for the correction of the error caused by the iron at once became the guide for future practice. Besides the above, a further objection was raised which applied only to warships, namely, the nature of the damage which would be done to an iron ship by the enemy's shot: this also was found to be less serious, when proper appliances were supplied, than the damage done in the same circumstances to a wooden ship. Thus during the Chinese war in 1842 the *Nemesis*, an iron vessel, was able to repair her damage from shot in twenty-four hours at the scene of the fight, while some wooden ships which were damaged to about the same extent had to go to Bombay, the nearest port at which repairs could be carried out.

Steel, as a material for shipbuilding, was introduced under modern conditions of manufacture during the years 1870–75. It is a homogeneous metal, stronger than iron, and of a more uniform and more trustworthy character. Its quality is to a considerable extent independent of the skill of those employed in its manufacture, whereas iron is produced by a laborious and unhealthy process, and is largely dependent for its quality on the skill of the workmen. Among the advantages which experience has proved iron and steel to possess over wood for the purposes of ship construction are: (1) the structure of the ship has less weight; (2) it has greater durability; (3) the requisite general and local strengths are much more easily obtained.

The importance of the first of these advantages can scarcely be overstated. The primary object of a particular ship is to carry cargo or passengers, or both, from place to place, at a given speed (in the case of a warship, the armament, ammunition, armour, &c., constitute the weight to be carried); and since at the maximum draught at which the vessel can properly and safely proceed on her passage the total weight of vessel, cargo, &c., complete, must be a definite quantity, namely, the weight of the water displaced by the ship, it follows that the less the weight required for the structure of the ship, the greater is that available for the cargo, &c.

As to durability, in wooden ships the chief source of deterioration is dry-rot, in iron or steel ships the wasting of the surfaces, especially of such portions of the outer surfaces of the bottom plating as are frequently left bare of paint and exposed to the sea, and of the inner surfaces of the bottom in machinery spaces, &c. If dry-rot can be prevented, the life of the wood ship will be lengthened; so also will the life of the iron or steel ship if the surfaces can be kept covered with paint, to prevent the action of air and water. With both wood and iron or steel ships, if the parts which have become deteriorated can be removed and replaced, this is usually worth doing when the deterioration is only local. At the end of the 18th century the preservation of wood was not so well understood as it is at the present day, and teak, one of the most durable of woods, was, in Great Britain at least, little known. The ships for the Royal Navy as then constructed were only expected to be available for service some fifteen or twenty years. The ships built for the East India Company made, on an average, four voyages, which occupied eight years. This at one time was considered the vessel's life, so far as the Company's service was concerned; but subsequently, if on examination at the expiration of that time they appeared worth repairing, this was done, and they were allowed to make two more voyages. It was very unusual for one of these ships to make more than six voyages; after this they were sold for other services, or broken up. In certain cases, however, ships lasted a considerable length of time; a number of vessels built in the 17th century continued in the service of the Royal Navy until the middle of the 18th century, though with a reduced number of guns. Of small wood merchant vessels there are instances of the attainment of very remarkable age. The collier brig *Brotherly Love*, of South Shields, was over one hundred years old when she was broken up; and the schooner *Polly*, built in 1805, was still sailing in 1902; as also was the brig *Hvalfisken*, built at Calmar in Sweden in 1801. The dimensions of the last vessel are: length, 88 ft. 8 in.; breadth, 21 ft. 2 in.; depth of hold, 14 ft. 7 in.; and her gross tonnage, 211. We have so far had very little experience concerning the life of iron and steel ships properly taken care of, as in most instances these ships have been condemned only because they were obsolete; but when broken up, after twenty or even forty years' service, those parts which by accident or intention had remained properly covered and protected were found very

little the worse for wear. Thus the inner surfaces of the bottoms of such vessels, coated with cement, have been found to be in nearly as good condition as when the ships were first built.

That general and local strength is more easily obtained in an iron or steel ship than in a wooden one follows partly from the fact that the weight required for the structure is less in the former than in the latter, and also from the fact that iron and steel are more suitable materials for the purpose. They can be obtained in almost any desired shape, the parts can be readily united to one another with comparatively little loss of strength, and great local strength can be provided in very little space.

For some purposes, and in some markets, wood is still in favour; for instance, for resisting ice-pressure. In scientific expeditions to the Polar regions, also, it is of the highest importance to avoid any disturbance of the compass, and this can be ensured by constructing the vessel of wood, with metal fastenings. The *Fram*, built in 1892 for Nansen's Arctic expedition, was of wood, her outside planking, in three thicknesses, amounting in the aggregate to from 24 in. up to 28 in.; she was 117 ft. long, rigged as a three-masted schooner, and provided with auxiliary machinery working a screw propeller. The *America*, fitted out for the Ziegler expedition to the North Pole, was an old Dundee whaler (the *Esquimaux*), and was reported to be still a "stout" ship with timbers as sound as on the day they were put in thirty-six years before. She is 157 ft. long, 29½ ft. beam, 19¼ ft. deep, net tonnage 466; her engines have a nominal horse-power of 100, and she has a lifting screw. During the year 1901 a wood vessel, the *Discovery*, 172 ft. in length, was built at Dundee for Antarctic exploration; and in Germany another wood vessel for similar service has been constructed. On the other hand, in the *Ermack*, built on the Tyne for ice-breaking in the Baltic and for pioneer work farther afield, steel has been used as the most approved material for the service contemplated, and this after previous experience with similar vessels.

Some progress had been made in the introduction of steam propulsion before the end of the 18th century, but the advance became more rapid in the 19th. In the early steam vessels paddle-wheels only were used for propulsion.

Steam propulsion.

In 1801–02 the *Charlotte Dundas*, one of the earliest steam vessels, was constructed by Symington in Scotland. She proved her capability for towing purposes on the Forth and Clyde canal, but, although successful in the work for which she was intended, did not see much service, as the canal-owners feared the wash of the steamboat would damage the banks of the canal. About the same time Fulton made his experiments in France, and after visiting Scotland and witnessing the success of the *Charlotte Dundas*, constructed the *Clermont* on the East Hudson river in America in 1807. The engines for this vessel were obtained from Boulton and Watt, of England. She ran as a passenger boat between New York and Albany, and at the end of her second season proved too small for the crowd that thronged to take passage in her. In 1809 the *Phœnix* made the passage from Hoboken, in New Jersey, to Philadelphia, and was thus the first steamer to make a sea voyage. In 1812 Bell began running his steamer *Comet*, with passengers, between Glasgow, Greenock, and Helensburgh: she was 42 ft. long, 11 ft. broad, 5½ ft. deep, and her engine had one cylinder 11 in. in diameter, with a 16-in. stroke. Owing to the success achieved by these and other vessels in America and Great Britain, steamers soon began to make their appearance on many of the principal rivers of the world. Early in 1814 there were five steamboats on the Thames, and the steamboat *Margery*, built on the Clyde, was brought through the Forth and Clyde canal and round by the east coast to the Thames. In the same year a writer in the *Gentleman's Magazine* was able to say: "Most of the principal rivers in North America are navigated by steamboats; one of them passes two thousand miles on the great river Mississippi in twenty-one days, at the rate of five miles an hour against the descending current." In 1816 the first steam passenger-boat ran across the English Channel from Brighton to Havre, and a line of steamers was started to run between New York and New London. All of these vessels were built of wood; but in 1820 the first iron steamship, the *Aaron Manby*, was constructed and employed in a direct service between London and Paris. In 1822 a return was made to the House of Commons showing the times occupied by steamers as compared with sailing vessels on some thirty coasting routes: the average speed given for steamers in the best of these was from eight to nine knots, while the average time taken varied from one-half to one-sixth (or even less) of the time taken by the sailing vessels.

Steam vessels were employed at a very early date upon the mail services, for besides being very much quicker than the sailing vessels, they were practically independent of the direction of the wind, and to a considerable extent of the weather; consequently the regularity of their passages contrasted very favourably with the irregular times kept by the sailing vessels. The mail service across the Irish Channel, between Holyhead and Dublin, was especially uncertain in the days of the sailing packets, frequently occupying three or four days, and occasionally as much as seven and nine days. All this was altered when in 1821 the steamers *Royal Sovereign* and *Meteor* were placed on the service. The advantages were so apparent that steam mail packets between Great Britain and the Continent, and on many other services, were soon established. The mail boats had been for many years owned by the Crown, but in 1833 the carrying of the mails to and from the Isle of Man, and between England and Holland and Hamburg, was entrusted to private companies. Marked improvement in the services, and especially in the boats employed, resulted from the competition to secure the distinction and other advantages of carrying His Majesty's mails. An intermediate stage followed, extending over a comparatively short period, during which the Crown still held many of the mail boats, while in a considerable number of cases the mail services were let to private companies. After this the British Government abandoned altogether the policy of being the owners of the boats, and ever since, the mail services have been competed for by private companies.

The *Savannah* was the first steamship to cross the Atlantic. She ran from Savannah to Liverpool in 1819 in twenty-five days, under steam, however, only for a portion of the time. She was built at New York as a sailing ship, but before launching was fitted with steam power, the paddle-wheels being arranged to be removed and placed on deck when not required. She was 130 ft. long, 26 ft. broad, 16½ ft. deep, and of about 380 tons. The success of the *Enterprise*, of 470 tons, which made the voyage from London to Calcutta by the Cape of Good Hope in 1825 in 103 sailing days, is noteworthy. The distance is 11,450 nautical miles, and the vessel was under steam for 64 days and under sail for 39 days. The steamer afterwards (1829–30) made the trip between Bombay and Suez in 54 days, in furtherance of a scheme to reach the former place from London by the Red Sea route. The year 1838 witnessed the successful trans-Atlantic voyages of the steamers *Sirius* and *Great Western*. The latter vessel, built under the advice of I. K. Brunel, the engineer of the Great Western Railway Company, was the first steamer actually constructed for the trans-Atlantic service. She was built of wood, her dimensions being—length 212 ft., breadth 35½ ft., depth 23¼ ft., and tonnage 1340 B.O.M.; and her total displacement on a draught of 16 ft. 8 in. was 2300 tons. Although not originally built for the service, the *Sirius* was subsequently placed on it at the recommendation of Mr M'Gregor Laird of Birkenhead. This vessel also was built of wood, and was 178 ft. long, 25½ ft. broad, 18¼ ft. deep, and her tonnage was 703. Mr Laird's arguments in favour of placing the vessel on the trans-Atlantic service throw light on the steaming capabilities of vessels of that day. He pointed to the steamers *Dundee* and *Perth* making 11 miles per hour, "in all weathers, winter and summer, fair and foul"; and to the other vessels making from 10 to 10½ miles per hour. He based his estimate for the coal required on the voyage on a speed of 10 miles per hour and a coal consumption of 30 tons per day, which gave 525 tons for the whole voyage. Finally, he allowed 800 tons, corresponding to the difference of the displacement at 15 ft. load draught and at 11 ft. light draught, so that he had a margin of 275 tons for contingencies. (See also STEAMSHIP LINES in this volume.)

All the vessels just named were propelled by paddle-wheels, but in 1843, in the *Great Britain*, screw propulsion was adopted for the Atlantic service. The screw propeller had been introduced a few years before by Ericsson, of Sweden, and by F. P. Smith, of Hendon, in Great Britain. The *Archimedes*, fitted by the latter investigator, had, after some very remarkable trials, been acquired by Brunel for further experiments, and as a result the paddle-wheel engine design, originally prepared for the *Great Britain*, was discarded, and a design for screw engines

substituted. The advantages of the screw over the paddle-wheel for war-vessels were recognized about this time by the British Admiralty. These advantages were chiefly that the screw did not interfere to the same extent as the paddle-wheel with the sailing qualities of the ship, and that it was protected against injury in action by its position below the surface of the water, while the latter was very liable to injury. In a few years the screw almost entirely superseded the paddle-wheel for war-vessels, and in 1854, during the war with Russia, Great Britain possessed a screw steam fleet, including all classes of ships, built of wood.

The performances of the *Great Western* and other vessels had demonstrated that ships could traverse the oceans of the world by steam power alone, but great advance had to be made in the marine engine before the ordinary trade could be carried on by its means with economy. In the early marine engines only one cylinder was provided, and various means were employed for transmitting the power to the paddle shaft; later came the oscillating cylinder engine and the diagonal engine, the latter being the type of paddle engine now most frequently adopted in Great Britain. With the introduction of the screw-propeller the arrangements became much modified. At first the engines were run at comparatively low speeds, as in paddle-boats, gearing being supplied to give the screw-shaft the number of revolutions required, but direct-acting two-cylinder engines gradually replaced the geared engines. The compound engine was first adapted successfully to marine work by John Elder in 1854, and in time the direct-acting vertical engines, with one high and one low pressure cylinder, became the common type for all ships. The boiler pressure, moreover, in 1854, had been raised to 42 ℔ per square inch. The further change, accompanying still higher pressures of steam, from compound to triple-expansion engines was, like many other changes, foreseen and in some measure adopted by various workers at about the same time, but the first successful application of the principle was due to Dr A. C. Kirk. In 1874 he fitted a three-crank triple-expansion engine in the *Propontis*. The boiler used proved a failure, but in 1882 he fitted a similar set of engines in the *Aberdeen*, with a boiler pressure of 125 ℔, and the result was entirely successful. All modern marine engines of high power have either triple or (in a few cases) quadruple expansion.

Statistics of ship-building.

Notwithstanding the early advances made in the introduction of iron for construction purposes, and steam for that of propulsion, the bulk of the trade of the world was still carried on as recently as 1870 by wooden sailing ships. At that date, however, the building of wood vessels had already begun rapidly to decline, so far as Great Britain was concerned, and this decline has continued at an almost uniform rate down to the present day. On the other hand, the construction of iron vessels had in 1870 begun to increase at a greater rate than that of the decline in the construction of wood vessels; and including steel with iron ships, this increase, apart from fluctuations due to waves of trade and depression, has continued down to the present time. For some years previous to 1870 the construction of sailing vessels had gradually decreased, the decrease nearly corresponding to the rate of increase in the construction of steam vessels. But while from 1870 nearly down to the present day, apart from fluctuations, the construction of sailing vessels has remained generally constant, the construction of steam vessels has, on the other hand, rapidly increased. These changes for Great Britain will be clearly seen on examination of the figures given in Table I., but they are represented graphically and much more completely by the curves in Figs. 1 and 2.

It will be seen from Table I. that during 1860 there were 181 iron ships, of 100,830 tons aggregate, and 835 wood ships, of 161,180 tons aggregate, added to the register of the United Kingdom. Soon after 1860 the production of iron ships exceeded the production of wood ships, and whilst in 1870 there were 445 iron ships, of 408,510 tons aggregate, added to the register, there were only 529 wood ships, of 80,262 tons, added to the register; during 1880 there were 431 iron and steel ships, of 525,568 tons, added, and only 293 wood ships, of 19,938 tons. The general increase in iron and steel ships and the diminution in wood ships continued, until in 1900 there were 613 iron and steel ships, of 1,128,283 tons, and only 223 wood ships, of 12,527 tons, added to the register. It will be seen from Table I., but more clearly from Fig. 2, that although during the last few years of the period the amount of sailing tonnage registered fell off considerably, yet for some twenty to thirty years previously the amount registered did not show any general falling-off. On the other hand, a rapid advance in the construction of steamships is shown;

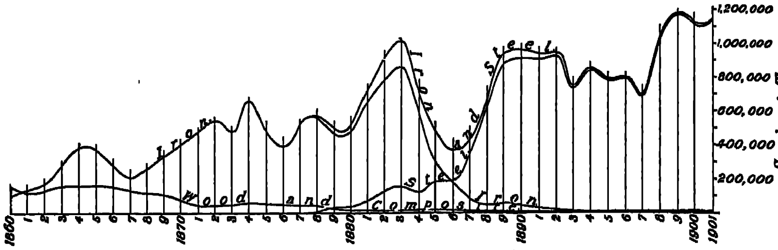

FIG. 1.—Gross tonnage of all wood, composite, iron and steel merchant vessels over 100 tons gross built in and added to the register of the United Kingdom during each year from 1860 to 1901.

in 1870 there were 364,860 tons added to the register, in 1880 there were 485,661 tons added, and this general rate of increase was maintained until in 1900 the total added reached 1,123,074 tons. The variations in the rates of production, due to fluctuations in trade and other causes, will be seen at a glance from Figs. 1 and 2, in which the ordinates of the curves represent tons of shipping produced and registered in the United Kingdom during the year, and the abscissæ represent time. It will be seen that the decline in the production of wood and composite vessels has been fairly uniform since 1870, whereas the variations in the production of iron and steel ships have been exceedingly great. These variations synchronize with the improvements and depressions in trade which took place over the period named. The curves in Fig. 1 show how

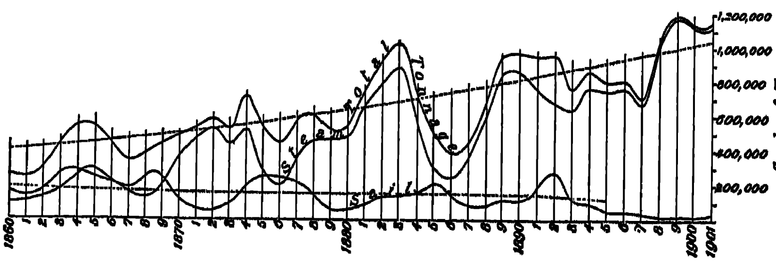

FIG. 2.—Gross tonnage of all sailing and steam merchant vessels over 100 tons gross built in and added to the register of the United Kingdom during each year from 1860 to 1901. The dotted lines may be taken as representing the average production from year to year.

rapidly steel displaced iron as a material for shipbuilding. So rapid indeed was the change that the great depression between 1883 and 1886 had little or no effect in reducing the production of steel ships during these years. As might have been expected, the variations in the curve of steam vessels (Fig. 2) correspond generally to the variations in the curve of iron and steel vessels in Fig. 1.

From Table II., which gives the distribution of ownership of existing merchant vessels and other vessels, excepting warships, of 100 tons and upwards throughout the world, it appears that the total tonnage of the existing shipping, excluding vessels under 100 tons, but including the wood vessels on the Great Lakes of America, is about 30½ millions. Of this total, rather more than one-fifth is in sailing vessels, and the remainder in steam vessels. Taking the number of ships instead of their aggregate tonnage, the sailing vessels are 43 per cent. of the whole. Out of the 30½ million tons, Great Britain and her colonies own about 14¾ millions, or 48 per cent. of the whole, 12¾ millions being steamers and 2 millions sailing vessels. Next to Great Britain, the largest ship-owning country of the world is the United States of America, with 3 million tons of shipping, nearly 10 per cent. of the total. Then come in order Germany, with nearly 3 millions, 9½ per cent. of the total; Norway, with 5·3 per cent.; France, with 4·6 per cent.; Italy, with 3·6 per cent.; and Russia and Spain, with 2·6

TABLE I.—*Showing the Number, Tonnage (Gross and Average), and Description of all Vessels (excluding Warships) built in and added to the Register of the United Kingdom during each year enumerated.*

The above table has been taken from information supplied to Lloyd's Registry by the Registrar-General of Shipping.

* As no actual returns are available for the gross tonnages for the years from 1860 to 1879 inclusive (only net tonnages having been recorded), the gross for these years are only approximate, and are based on the relation of gross to net for the years 1883 to 1900.

per cent. each. The leading particulars as to the distribution of ownership of the merchant shipping throughout the world for 1873, 1890, and 1901 respectively are represented graphically in the three diagrams given in Fig. 3. These have been constructed from particulars given in Table II. and similar tables for 1873 and 1890. Warships, all vessels under 100 tons, and the wood vessels on the Great Lakes of North America, unless known to be employed in sea trade, are not included. The total tonnage owned throughout the world in these years, with these exceptions, is represented by squares drawn to the same scale, and these squares are divided up amongst the principal countries owning shipping, a small area on the right-hand side of each representing a number of holdings too small to be shown separately. Part of each holding is shaded so as to show what portion of this is sailing tonnage and what portion is steam tonnage. The total tonnage owned is given in the heading, and this is represented by the square shown for each year. The percentages owned by various countries are tabulated; and on each square the proportion of the shipping of the day which was severally steam and sailing is also recorded. For 1890 and 1901 in Fig. 3 there is also shown the distribution of the total as regards materials of construction in each country. The tonnage of the shipping of the world has advanced at an increasing rate for many years. The character of this rate will be gathered at once from the data given in Fig. 3. In 1873 Great Britain and her colonies owned 43¼ per cent. of the shipping of the world, and this number rose in 1880 to 52 per cent.; but in 1900, although the advance in the shipping of Great Britain and her colonies had continued approximately at the same uniform rate, such was the increasing rate of the advance of the world's shipping that the percentage owned by the British Empire had fallen to 48·65.

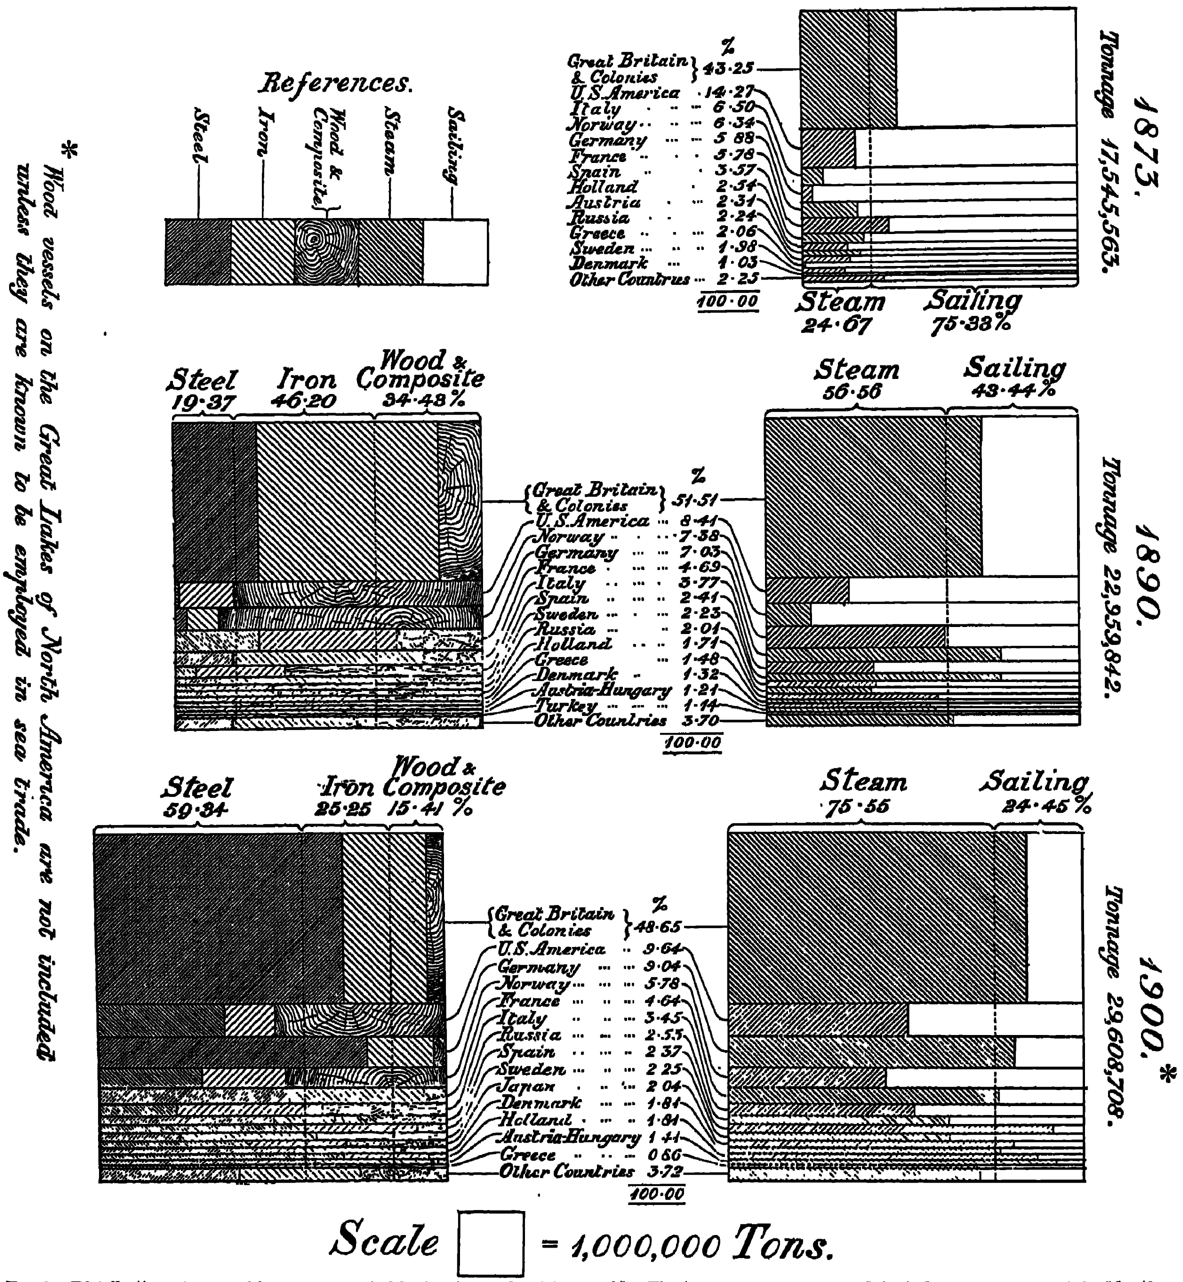

FIG. 3.—Distribution of ownership of merchant shipping throughout the world. The tonnages are gross, and include, so far as ascertainable, those of all vessels over 100 tons in existence at the dates specified, with the exception of wood vessels on the Great Lakes of North America.

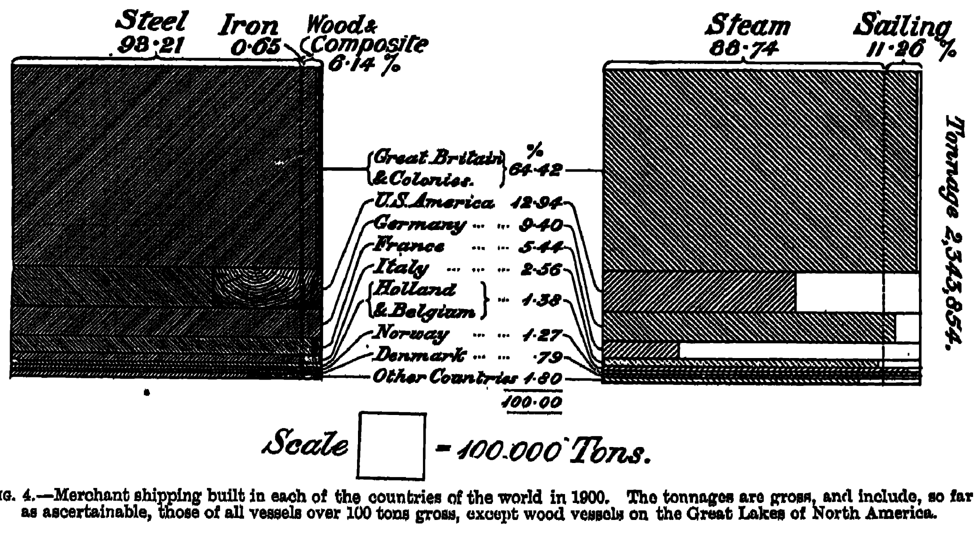

FIG. 4.—Merchant shipping built in each of the countries of the world in 1900. The tonnages are gross, and include, so far as ascertainable, those of all vessels over 100 tons gross, except wood vessels on the Great Lakes of North America.

TABLE II.—*Shipping owned in each Country of the World (extracted from Lloyd's Register of British and Foreign Shipping for 1901–02).*

* Wooden vessels belonging to ports situated on the Great Lakes of North America are not included in the Register Book unless they are known to be employed in sea trade, but from the report of the American Commissioner of Navigation, dated June 1890, there were at that date registered on the Great Lakes 2845 wooden vessels, having a gross tonnage of 877,818, the net tonnage not being recorded.

† In the absence of satisfactory information, the records of numerous small sailing vessels, belonging chiefly to Greece, Turkey, Southern Russia, and the Dutch East Indies, have been omitted from the Register Book.

TABLE III.—*Number, Gross Tonnage, and Description of all Vessels of 100 Tons gross and upwards built in each of the several Countries of the World, during the Year 1900, according to Lloyd's Register Book for 1901–02.*

Country in which Built.	Whether Sail or Steam.	Wood and Composite. 100 to 999 Tons.	1000 to 1999 Tons.	2000 to 2999 Tons.	3000 to 3402 Tons.	Total. No.	Total. * Excluding wood vessels built on the North American Lakes

This decline has been chiefly due to the increasing rate at which the shipping of the United States of America and of Germany has advanced.

Table III. gives the output of merchant and other vessels throughout the world in 1900, excluding warships, all ships of less than 100 tons, and the wood vessels of the Great Lakes of North America. It will be seen that the total output for the year was 2,343,854 tons, of which 1,509,837 tons, or 65 per cent. of the whole, was built in the United Kingdom and the British colonies; 13 per cent. by the United States of America; 9·3 per cent. by Germany; and 4·5 per cent. by France. The leading particulars given in Table III. are represented graphically in Fig. 4, which is similar in its construction to the diagrams of Fig. 3. The total tonnage built in 1900 is made up of 972 steamers, of which 59 were wood or composite, and 913 of iron or steel; and 324 sailing vessels, of which 218 were wood or composite, and 106 of iron or steel. Of the 913 steamships built of iron or steel, 70 only were of iron, and these were all below 400 tons each. Thus iron has practically ceased to be used, except for some special purposes. Forty steel sailing ships of over 1000 tons were built in France, their aggregate tonnage being about 93,000, the production of these vessels being no doubt due in large measure to the French shipping bounties, which favour their construction. The relative sizes of the iron and steel ships built in different countries is worthy of note: thus the mean tonnage of those vessels built in Germany was 2354; of those built in Italy, 3626 tons; whilst of those built in Great Britain it was only 2258 tons.

The average increase in size of ships registered in the United Kingdom from 1860 down to the present time is well shown by the figures of Table I. For iron and steel ships combined the average size of those registered in 1860 was 560 tons; in 1870 it was 920 tons; in 1880, 1220 tons; in 1890, 1580 tons; and in 1900 it was 1840 tons. These figures may be taken as representing the general increase throughout the world; but as in these averages large numbers of comparatively small vessels are included, the vast increase in the number of large-sized ships which have been built, especially during recent years, is not adequately represented. Of the vessels built in 1890 only 1 per cent. exceeded 8000 tons in displacement, whereas the vessels of over 8000 tons built in 1900 made up 12 per cent. of the whole tonnage. In 1890 there were no vessels built whose displacement exceeded 9000 tons; in 1900 such vessels constituted $11\frac{1}{2}$ per cent. of the whole, and about $\frac{3}{4}$ per cent. of the whole were over 16,000 tons.

Merchant Vessels.

Generally speaking, so far as the distribution of sails is concerned, except as regards the abolition of studding-sails, the sailing ships of to-day differ little from those which existed in the middle of the 19th century, and in case of many types at a much earlier period. The change from wood to iron and steel resulted, of course, in some changes in rig, to suit the longer and larger vessels; and steel masts, with wire rope standing rigging and various labour-saving appliances, have been introduced. The larger ships also carry steam winches for various purposes, steam windlasses, and steam steering gear, but the general appearance of the vessels has changed very little.

Sailing ships.

Barges.—Rivers and canals abound with barges of various types, such as the Thames barge, the Tyne wherry or keel, and the Dutch galliot or pink. The Thames barge, which may be taken as a representative vessel of this class, has a length of from 70 to 80 ft., and a carrying capacity of from 100 to 120 tons on about 6 ft. draught. Like the Dutch galliot, she is provided with lee-boards, and is fore-and-aft rigged with sprit-sail and jigger.

In recent years the use of barges or lighters has been extended beyond river and canal service, and a rapidly increasing number are now used, in addition, for sea transport. For example, on the east coast of England lighters of about 500 tons carrying capacity are used in the coal trade. These are loaded on the Tyne, sent down the river, towed from its mouth to the Nore, and sent up the Thames to London. By this means the tug spends very little of her time going up and down rivers, and waiting at docks and wharves, and saving is effected on account of the small capital cost for the lighters, as well as their low cost of maintenance. The system has been carried much farther on the Great Lakes of North America, where cargo barges are in use of over 350 ft. in length, and approaching 5000 tons displacement when loaded. There, however, it appears to have reached its limit, as the building of such vessels shows signs of falling off in favour of steamers of about the same carrying capacity; but on the east coast of the United States the practice is still growing, and barges, built sometimes of wood and sometimes of steel, are employed, carrying from 2000 to 4000 tons of coal, oil, grain, &c.

Smacks or Cutters.—This type of rigging is still largely adopted in the merchant service for small vessels, usually called smacks, of a length, say, from 60 to 90 ft., and a displacement from 150 to 200 tons. They are single-masted, sharp-built vessels, provided with fore-and-aft sails only, and fitted with a running bowsprit; they have no standing jib stay. Such vessels were at one time generally used for coasting passenger traffic. The term "cutter" is also applied to an open sailing boat carried on board ship.

Schooners, Brigs, and Brigantines.—A schooner (Fig. 5, Plate I.) is usually a two-masted vessel, with yards only on the foremast and fore-and-aft sails on the main. The foresail is not bent to the yard, but is set flying. In some cases there are no yards at all; and the schooner is then called a fore-and-aft schooner, a schooner with yards being sometimes called a square-rigged schooner. Before the days of steam, two- and three-masted schooners, known as "Fruiterers," were extensively employed in the fruit trade from the Western Islands, Italy, Malta, and other orange-growing countries to London. In the 'fifties as many as three hundred were thus employed; they kept their place till the 'eighties, and some even yet survive the introduction of steam as a motive power. They were beautifully modelled craft, and very fast under canvas. A brig is a two-masted vessel having yards, or square-rigged on both masts. A brigantine is a two-masted vessel having the foremast square-rigged, as in a brig, the main mast being rigged as in a schooner. Much of the coasting trade of the world is carried on by schooners, brigs, and brigantines. These vessels were formerly employed in the Baltic, and to some extent in the West Indies and the Mediterranean. Schooners such as the above are usually from 80 to 100 ft. long, 20 to 25 ft. broad, 10 to 15 ft. deep, and have a gross tonnage of 130 to 200 tons. Brigs are generally larger, varying in tonnage from 200 to 350 tons; they are from 90 to 115 ft. long, from 24 to 30 ft. broad, and from 12 to 18 ft. in depth of hold. Brigantines usually occupy, as to size, a position intermediate between schooners and brigs. Brigs are used in various navies for the purpose of training boys. Some six exist at present in the British navy, and are stationed at Devonport and Portsmouth.

Vessels somewhat larger than two-masted schooners and brigs, but of a similar form, are often rigged as three-masted schooners and as the so-called barquentines. The former is like a schooner with a third or mizzen mast added, this being rigged fore and aft, as is the main mast. The latter resembles a brigantine with a third mast added, which is also fore-and-aft rigged. The two rigs thus very nearly resemble each other: both are square-rigged on the foremast, and fore-and-aft rigged on the main and mizzen; but while in the former the foresail is set flying, in the latter it is bent to the yard.

Larger vessels than these are sometimes fitted with four, five, six, and even seven masts, as fore-and-aft schooners. A large number of vessels fitted in this manner are much in favour for the coasting trade of America. Fig. 6 (Plate I.) shows the *Helen W. Martin*, a five-masted wooden schooner, built in 1900 in the United States; she is 280 ft. 6 in. long, 44 ft. 9 in. broad, and 21 ft. depth of hold, and her gross tonnage is 2265. Another vessel built at the same time, also of wood, and named the *Eleanor A. Percy*, is 319 ft. 3 in. long, 48 ft. 9 in. broad, and 23 ft. depth of hold, with a gross tonnage of 2970; she is rigged as a six-masted schooner. An interesting vessel of this class is a seven-masted schooner, under construction in 1902 by the Hore River Ship and Engine Co., Quincy, Mass. This vessel is of steel, 368 ft. long, 50 ft. beam, $34\frac{1}{2}$ ft. depth of hold, and on a draught of 26 ft. 6 in. will be of 10,000 tons displacement, thus being the largest sailing vessel yet constructed. These three must all be regarded as ocean-going vessels.

Barques and Ships.—Vessels intended to sail to all quarters of the globe are usually rigged as barques or ships; but, as indicated above, these rigs are very far from embracing all those in use; many others are very common. A barque is a three-masted vessel, square-rigged on the two foremost masts (the fore and main masts) and fore-and-aft rigged on the mizzen mast. A ship (a ship-rigged vessel) has three masts, each of which is square-rigged. These were the rigs employed in types of vessels now fast passing away, if indeed they must not be considered as already obsolete, in which great speed was the quality chiefly aimed at, and carrying power was of secondary importance. For instance, the *Phœnician*, built in 1852, had a length of 150 ft. and a net tonnage of 478; the *Shannon*, built in 1862, was 217 ft. long and her tonnage 1292. The former made the quickest run on record, up to 1852, from Sydney to London, accomplishing the distance in 83 days; and the latter made a round voyage from Melbourne to London and back from thence to Sandbridge Pier in 5 months and 27 days, handling two full cargoes in the time. The American ship *Witch of the Wave*, built in 1852, and the British ship *Cairngorm*, built in 1853, were engaged in the keen competition carried on between Great Britain and the United States for the rapid conveyance of

early teas from China to London. The American builders had for some years been more successful than the British builders, and the *Cairngorm* was the first ship which equalled the American ships in speed, and it was, moreover, claimed for her that she delivered her cargo in better condition than the American ships. She was 215 ft. long, and her tonnage was 1250 old measurement, or 938 new measurement. The *Witch of the Wave* on her best voyage made the passage from Whampoa to Dungeness in 90 days, the best day's run being 338 knots in 24 hours, a very remarkable performance. Later, in 1856, the *Lord of the Isles* beat the two fastest American clippers then existing in a race from China to Great Britain, one of them only by a few minutes; her length was 183 ft., and her tonnage, new measurement, 630. It is noteworthy that the competition in bringing the early teas home from China, started between British and American ships, was carried on subsequently between British ships alone. In the memorable race of 1866 from Foo-Chow to London, five ships, the *Ariel*, *Taeping*, *Serica*, *Fiery Cross*, and *Taitsing* took part. The first three left Foo-Chow the same day—the *Ariel* first, followed 20 minutes later by the *Taeping* and *Serica* together. The vessels separated, and lost one another till they reached the English Channel, when the *Ariel* and *Taeping* got abreast, and raced to the Downs, the former arriving some ten minutes before the latter, the *Serica* reaching the Downs a few hours later. These three occupied 99 days on the voyage; the *Fiery Cross* and *Taitsing* took two days longer, making the passage from Foo-Chow to the Downs in 101 days. The best day's run on the passage for all these ships differed but little, the *Fiery Cross* showing a slight superiority in this respect, having run 328 knots in the 24 hours. The time occupied in the above voyages was beaten in 1869 by the *Thermopylæ* and *Sir Lancelot*, both British ships and of composite build; the times occupied by their passages were respectively 90 days from Foo-Chow to Dungeness for the former, and 88 days from Foo-Chow to Deal for the latter, each taking one day more to get into the docks. The dimensions of the *Thermopylæ* were 212 ft. by 36 ft. by 21 ft. depth of hold, and of the *Sir Lancelot* 197½ ft. by 33⅝ ft. by 21 ft. The best day's run of the *Sir Lancelot* was 354 knots in 24 hours. Shortly before the above voyage the *Thermopylæ* made the passage from London to Melbourne in an unprecedentedly short time, namely, 62 days from Gravesend to Port Phillip harbour. With the opening of the Suez Canal and the general introduction of steam, the demand for exceptionally fast sailing vessels of these types has very considerably diminished, and, indeed, almost ceased to exist. The type of cargo sailing ship usually met with to-day is better illustrated by Fig. 7 (Plate I.), which represents the *Victoria Regina*, built of iron in 1881 at Southampton; she is 270 ft. long and has a gross tonnage of 2006. Although she has a good spread of canvas and is a fast vessel, she carries a very large cargo for her dimensions.

Ships with four and five masts were employed by several countries during last century. Sometimes, in the case of four-masted ships, these were square-rigged on the fourth or mizzen mast, and sometimes fore-and-aft rigged, in which case they are called four-masted barques in Great Britain and shipentines in America. Five-masted ships are sometimes square-rigged on the fourth mast and fore-and-aft rigged on the fifth mast, and sometimes fore-and-aft rigged on both of these masts. The *Naval Chronicle*, vol. vii., 1802, contains particulars of the French privateer *L'Invention*, shown in Fig. 8 (Plate I.), which was captured by the British ship *Immortalité*; she was rigged as a four-masted ship, carried 26 guns, and had a complement of 220 men. It is remarkable how little her rig differs from that of modern vessels. A five-masted vessel is described in the same number of the *Naval Chronicle* which was square-rigged on the foremast and fore-and-aft rigged on the other four masts; she was apparently a forerunner of the American five-masted schooner of the present day. The shipentine clipper *Great Republic*, built in 1853, is noteworthy as being the first ship fitted with double topsails, now so generally adopted. She was 305 ft. long and her tonnage was 3400; she could spread 40,500 square ft. of canvas, excluding stay-sails; she had four decks and was built of wood, though her framing was diagonally braced with iron. The shipentine *Madeleine*, built in France in 1896, is almost identical in rig to the *Great Republic*; her length is 321 ft. and her gross tonnage 3026. A five-masted barque *France*, built in Glasgow in 1890, is 361 ft. long and has a gross tonnage of 3942. As further examples of the large sailing ships built in recent years may be mentioned the *Astral* and *Potosi*. The *Astral* was built by Arthur Surall and Co. at Bath, Maine, in 1900, for the oil trade. She is a full-rigged four-masted ship, 332 ft. long, 45½ ft. beam, 26 ft. moulded depth, gross tonnage 3292, and intended to carry 1,500,000 gallons of oil in cases of 10 gallons each from the United States to Shanghai, returning with cargoes of sugar, hemp, &c. The masts and yards of this vessel, as well as the hull, are of steel. The five-masted German barque *Potosi*, built in 1895, which is 366 ft. long, has a gross tonnage of 4027 and a dead-weight capacity of 6200 tons; she has a splendid record of quick passages, one reducing the record from Portland Bill to Iquique to 62 days.

As instances of the times occupied on the voyages of modern sailing ships the following may be given:—66 days from Iquique in Chile to the English Channel by the British ship *Maxwell*, gross tonnage 1856; 29 days from Newcastle, New South Wales, to Valparaiso by the British four-masted ship *Wendur*, 2046 gross tonnage; 30 days from the Lizard to Rio de Janeiro by the British ship *Salamanca*, of gross tonnage 1262; and 78 days from Dover to Sydney for the same ship; 153 sailing days for a voyage round the world, made up of 50 days from Cardiff to Algoa Bay, 28 days from Algoa Bay to Lyttelton, and 74 days from Lyttelton to the Lizard, by the British ship *Talavera*, gross tonnage 1796; 59 days from Cape Town to Iquique by the British ship *Edenballymore*, of gross tonnage 1726; 88 days from San Francisco to Queenstown by the British four-masted barque *Falls of Garry*, of gross tonnage 2088; and 69 days from Scilly to Calcutta in 1876 by the *Coriolanus*, gross tonnage 1074. Amongst the voyages recorded recently by German ships the following may be enumerated:—71 days from Iquique to Hamburg by the ship *Preussen*, gross tonnage 1761; 58 days from the English Channel to Valparaiso by the four-masted barque *Placilla*, gross tonnage 2845; 71 days from the English Channel to Melbourne by the barque *Selene*, gross tonnage 1319; and 69 days from the English Channel to Adelaide by the four-masted barque *Hebe*, of gross tonnage 2722.

Although alterations in the rigs of ships have not caused much difference in their appearance over a very long period, a number of changes have been made, mostly for the purpose of saving labour. The mechanical reefing of topsails and top-gallant sails was introduced about 1858, but only remained in favour for a few years; double topsails, on the other hand, first used in the four-masted American clipper ship *Great Republic*, have held their own, and double top-gallant sails have since been adopted. Until about 1875 almost all ships carried studding-sails, but since this date they have been gradually discontinued, and at present are usually only to be found in training vessels, and now and again in square-rigged yachts. As already stated, wire rope has been adopted for standing rigging, and deadeyes and lanyards have given place almost universally to rigging screws. Masts and the heavier yards have been made of iron for many years, and more recently of steel, and the lower masts and top masts have in a number of cases been made in one length; when constructed in this manner the mast is termed a pole mast. This arrangement is very common in America, where the latest steel sailing ships are so fitted. Most large sailing ships carry a steam boiler or boilers, and engines are provided for all sorts of purposes, for which hand labour used to be commonly employed. The result of this and other labour-saving arrangements has been to effect a very considerable reduction in the number of hands carried. As indicating the nature of the change which has taken place, it may be mentioned that whereas a 1000-ton ship of the East India Company in the middle of last century had a crew of 80 all told, a modern four-masted barque of 2500 tons has a total complement of 33 only.

As to the employment of sailing ships, there can at the present day be seen at most large shipping ports a number of sailing ships of various types and sizes. Some of the largest ships are employed in the jute trade of India, the grain trade of California, British Columbia, &c., and the nitrate trade of Chile. From Great Britain they usually take out coal, which, however low freights may be, may in nearly all cases be relied on.

Steam-ships.

Of merchant steamships, vessels of all sizes are to be met with, from a small launch to the stately Atlantic liner of 16,500 tons gross and 23½ knots speed, and the huge cargo ship of over 20,000 tons gross and 15 knots speed. They are employed on every service for which sailing ships are used, and upon others for which sailing ships are not employed, and they monopolize nearly the whole of the passenger traffic of

the world. In general, the different sizes have no bold characteristic features such as distinguish sailing ships; they possess different deck structures and certain differences in form, but, to the ordinary eye, a photograph of a vessel of, say, 1000 tons, apart from details of known size that may serve to fix the scale, may often be taken to represent a vessel of even ten or twenty times the size.

Merchant steamships may be classed into various types. There are *Flush-deck Vessels*, in which there are no deck structures, beyond possibly engine and boiler casings; there are vessels which have a *Monkey Forecastle* forward, from which the anchors are worked, a small poop or *Hood* aft to protect the steering gear, and a deck-house under the bridge amidships, called a *Bridge House*. Some have a complete forecastle above the main deck, called a *Top-gallant Forecastle*, with a corresponding *Poop* and a *Bridge House;* some have a *Top-gallant Forecastle* and a *Bridge House* associated with simply a *Raised Quarter-deck*. In others the bridge house and poop join one another, when the vessels are described as having a *Top-gallant Forecastle* with a *Long Poop* and *Bridge House* combined, and are known as *Well-decked Vessels*, a name also applied to vessels in which the *Bridge House* joins a *Raised Quarter-deck*. The foregoing types include most small vessels, but comparatively few very large-sized vessels. Most of the latter have a continuous upper deck above the main deck: if this be of light construction, and openings be left between it and the main deck, the vessel is called a *Shade-decked Vessel;* if there be no openings between the decks, she is called an *Awning-decked Vessel;* if there be no openings and the scantlings be somewhat heavier, she is called a *Spar-decked Vessel;* and if the scantlings be heavier still, she is called a *Three-decked Vessel*. Besides the above, vessels are built with almost every other conceivable variation of these features, and there are in addition *Turret-deck Vessels*, *Trunk-deck Vessels*, and *Whale-back Vessels*, the last named being peculiar to the Great Lakes of North America.

Sailing ships with machinery of low power, for use in calms and in getting into port, are called *auxiliary* steamships. In the early days of steam all sea-going vessels provided with means of steam propulsion may be said to have come under this description. The screw propeller offered less obstruction than paddle-wheels when the sails were set and the engines stationary, but the resistance caused by the screw when not in use led to a number of devices for either lifting it completely out of the water, or for fixing its blades in positions so as to offer the least obstruction in going through the water. Auxiliary steam yachts have in the present day many friends. In them the pleasures of sailing may be secured with a fair amount of certainty of making port when desired. Small vessels intended for seal and whale fishing are sometimes fitted as auxiliary steamships: six such vessels, all barque-rigged, and one of them fitted with a lifting screw, hailed in 1902 from Dundee, and a few also hailed from Norway, from Newfoundland, and from Bedford, U.S.A. Several navies possess auxiliary steam gunboats and other auxiliary steam vessels for service in distant parts of the world, and a few possess auxiliary steam training ships. The Chilian training ship *General Baquedano*, for example, built in 1899, of steel sheathed with teak and coppered, is 240 ft. long, 45¾ ft. broad, and has a displacement of 2500 tons on a mean draught of 18 ft.; she has a large spread of canvas and can steam 13 knots when required.

Steam Trawlers.—Screw steam trawlers are among the vessels frequently met with round the British coasts. As an example the *Anglesey* may be quoted. Built in 1898, she is 107 ft. long, with a beam of 20½ ft. and a depth in hold of 11 ft.; her gross tonnage is 158 and her net tonnage 52. One of the chief advantages which such vessels possess over sailing vessels lies in the certainty with which they can get to the fishing-ground, and then back again quickly to the market with their fish.

Tugs.—Smaller tugs are employed on canals and rivers and larger ones for ocean work. A sea-going steel tug, built by the Bath Iron Works, Bath, Me., for the American coal trade, is 165 ft. over all and 1045 tons displacement, with triple-expansion engines of 900 H.P. A paddle-tug, the *Flying Scotsman*, built in 1898, has a length of 118 ft., beam of 20 ft., depth in hold of 10 ft.; her gross tonnage is 177 and her net tonnage 29. A screw tug, the *Hannah Jolliffe*, built in 1900, is 103 ft. long, 23 ft. 6 in. broad, and 12 ft. deep; her gross tonnage is 178 and net tonnage 11. As already stated, one of the earliest uses to which steam vessels were put was for towing other vessels on canals and rivers, into and out of harbour, &c.; and in 1902 there was employed on the Clyde the paddle-tug *Clyde*, which was built of iron in 1851, of nearly the same dimensions as those of the vessels given above.

Colliers and Tank-steamers.—In a number of cases vessels are built to carry special cargoes; coal-carrying vessels, *colliers*, are well-known examples of this class. One of the first steam colliers was built at Wallsend as early as 1844, and called the *Q.E.D.* She was constructed of iron, had an over-all length of 150 ft., with a breadth of 27½ ft. She was propelled by a single screw driven by a 20-H.P. engine, and her dead-weight capacity was 340 tons. In certain respects she was a remarkable vessel, for she was fitted with a double bottom, the space between the bottoms being divided into tanks and arranged for water ballast, a system which is common in colliers, and indeed in most cargo ships. The advantage of the arrangement in the case of colliers is especially great, as they usually carry a full cargo one way and return empty. In their light condition sufficient water-ballast can be at once added to make them seaworthy, and this at the end of the voyage can be pumped out at a small cost. The *Wallsend*, a typical modern collier, is 210 ft. long, 30 ft. beam, 13 ft. 6 in. depth, and has a gross tonnage of 899, a net tonnage of 538, with triple-expansion engines. *Tank-steamers* form another example of vessels built for a particular cargo. Large numbers of these are employed in carrying oil in bulk from American and Russian sources, and from Borneo, to numerous ports all over the world. Their construction and the character of the material carried are such that they cannot be used to any considerable extent for any other purpose. Many of them are of large dimensions, while some are comparatively small. On the Caspian Sea, for instance, numerous small steamers are employed conveying oil from the Baku district to other ports, and to towns along the Volga. On the other hand, for longer passages when the demand is great, larger ships are employed, on account of their greater economy. As an example of a large oil vessel, the *Pinna*, engaged in carrying petroleum from Russian ports to the East, may be mentioned. She is 420 ft. long, 52 ft. broad, and 34 ft. deep, and she can carry 9000 tons of oil in her fully-laden condition. The machinery is placed well aft, and the cargo-space is divided up into twelve large tanks, extending to the height of the main deck, by seven transverse bulkheads and a longitudinal middle-line bulkhead. The spaces between the transverse bulkheads are called Nos. 1, 2, 3, 4, 5, and 6 holds respectively, and each hold has a port and a starboard tank. Each tank is provided with an expansion trunk, in order that the free surface of the oil may always be small, however much the bulk of the latter may expand or contract with changes of temperature.

Cargo Ships.—Many vessels are built to carry a particular cargo on one voyage and a general cargo on the return voyage. This usually results in their having certain features which adapt them for the special cargo, and do not interfere materially with their carrying a general cargo at remunerative rates. Usually, indeed, the object kept in view in constructing these vessels is to have as large a range of cargoes to choose from as possible, and the arrangements by which a particular cargo or particular cargoes can be carried are only provided with the view of achieving this object. Ordinary cargo ships, or "Ocean Tramps," as they are often designated, do a very large portion of the world's cargo-carrying. They may be of any size, and of any type required by the exigencies of trade, the fashion of the day, or the fancy of the owner. There is very little ornamentation about them, their decks even being often unsheathed with wood, but the greatest attention is paid to the arrangements for the rapid handling of the cargoes; they are mostly built of steel, and their usual speed is from 10 to 11 knots. In the early 'nineties well-decked vessels formed a large proportion of the total number; but ten years later comparatively few of this type were being built, and these were principally intended for the coal trade, or were comparatively small vessels for coasting purposes. Partial awning-deck steamers, again, which were much in favour at the same period, gave place, a decade later, to other types; and vessels having a raised fore-deck went entirely out of fashion, the tendency being to revert to flush-deck vessels, having short poop, bridge house, and forecastle.

TABLE IV.—*Types of Cargo Steamers.*

When built	A. Built in 1881.	B. Built in 1894.	C. Built in 1897.	D. Built in 1898.	E. Built in 1900.

Table IV. gives the dimensions, carrying capacity, and other leading particulars of five existing cargo steamers of different types, arranged in the order in which they were built. A is a well-decked vessel (Fig. 9, Plate II.), having a top-gallant forecastle with a long raised quarter-deck and bridge house combined, and is fitted with one deck, but has two tiers of beams. B (Fig. 10, Plate II.) is a vessel with a top-gallant forecastle, bridge house, and poop, and a single deck. C is an awning-decked vessel, with two decks, but three tiers of beams. D is a spar-decked vessel of 3222 tons gross, and E (Figs. 11 and 12, Plate II.) an American Lake steamer in which the draught was restricted to 18 feet. Besides the principal dimensions and light and load displacements, the block "coefficients" corresponding to the load conditions are given in Table IV., in order to show the fulness of form commonly adopted in these vessels. The *block coefficient* is the ratio of the volume of the immersed portion of the ship to the volume of the parallelopipedon, whose length, breadth, and depth are the same as the length, breadth, and mean draught (without keel) of the vessel

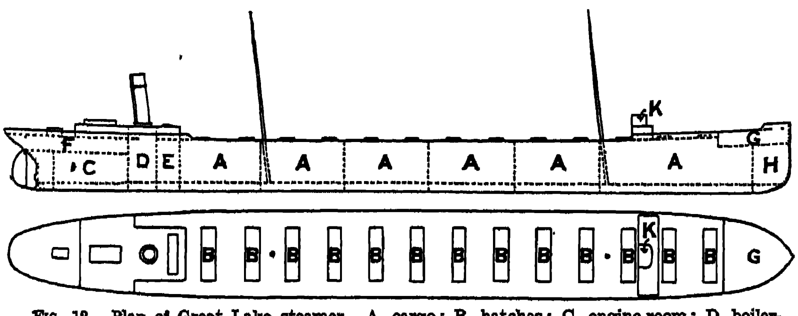

FIG. 12.—Plan of Great Lake steamer. A, cargo; B, hatches; C, engine-room; D, boiler-room; E, coal-bunker; F, accommodation; G, crew's space; H, water ballast; K, pilot-house.

itself; and it will be seen that in four cases out of the five given, the immersed volume, *i.e.*, the displacement, is 80, or upwards of 80 per cent. of this circumscribing parallelopipedon. The low speed, which is found economical for the "Ocean Tramp," admits of this fulness, and provides that capability for large stowage accommodation for cargo which has brought them into existence. In vessels whose speed is of great importance the block coefficient varies from ·5 to ·65, the lower limit being reached on the smaller vessels on cross-channel services, and the higher limit on very long vessels, such as the fast Atlantic liners. The total weight of material in the hull, *i.e.*, the iron or steel and woodwork, outfit, &c., and the propelling machinery, is called the vessel's *light displacement*. The *load displacement* is made up of the light displacement, together with the weight of the cargo, &c., or the dead weight carried; this, it will be seen from Table IV., varies from two to two and a half times the amount of the light displacement. This dead weight is fixed within certain limits by the builders and owners with regard to the safety and economical working of the ship, but British law provides that a vessel shall not be loaded deeper than a certain mark, known for many years as the Plimsoll mark, which has to be placed on the sides of all merchant vessels. The position of this mark, however, is, within certain limits, left to the discretion of the aforesaid builders and owners. The cargo capacity in cubic feet, the tonnage under deck, and the gross and net tonnage, are given in Table IV. for each vessel. The mode of measuring tonnage is based on the Act of 1854. (See TONNAGE.) The cubic contents of all closed-in spaces, available either for cargo or passengers, is calculated, and a ton of measurement is assumed to be provided by 100 cubic feet of space. Gross tonnage is the tonnage of all such spaces. "Under-deck" tonnage is the tonnage of spaces below the tonnage deck, which is defined as the upper deck in all ships having less than three decks, and the second deck from below in all others. The net tonnage is obtained from the gross by deducting an allowance for machinery spaces; for crew spaces, including accommodation for the master; for sail-room (in sailing ships) of not more than 2½ per cent. of the gross tonnage; for helm, capstan, and anchor gear, boatswain's store, and chart spaces. Thus net tonnage is the space which is available for the stowage of cargo. It has nothing to do with the displacement of the vessel or with the dead weight carried, to each of which the term tonnage is often applied. It will be seen from the table that in the vessels A, B, C, and D the net tonnage is less than one-half the dead weight carried.

Fig. 13 (Plate II.) is an example of a *Turret-deck* steamer, of which a considerable number have been built by Messrs Doxford of Sunderland. Her dimensions are: length 439 ft. 8 in., beam 51 ft. 7 in., gross tonnage 5995, and net tonnage 3794. Such vessels have the reputation of being good dead-weight carriers, and the shelf on each side of the central trunking can very conveniently be used for carrying timber, and for other purposes.

A general idea of the construction of a modern cargo steamer may be had by reference to Fig. 19 in the article on SHIPBUILDING. Fig. 14 shows the interior arrangements of the White Star *Cedric*, a vessel designed to carry a large amount of cargo in addition to many passengers.

Passenger Steamers.—There are numerous varieties of passenger steamers, both as to size and shape. For river service, where the traffic is considerable, paddle-wheel vessels of limited speed are usually preferred, as possessing great manœuvring power, and therefore the capability of being brought alongside the landing-places with rapidity and safety. The *King Edward*, a steamer which began to ply on the Clyde in 1901, is 250 ft. long, 30 ft. wide, 10 ft. 6 in. deep to the main deck, and 17 ft. 9 in. to the promenade deck. She was the first passenger steamer to be driven by Parsons's steam turbine, though she presents the usual appearance of a screw passenger vessel. Her speed is 20 knots. A second turbine steamer, the *Queen Alexandra*, began to run on the Clyde in 1902; she is generally similar to the *King Edward*, but larger and faster. The paddle-wheel steamer *La Marguerite*, which in the summer months

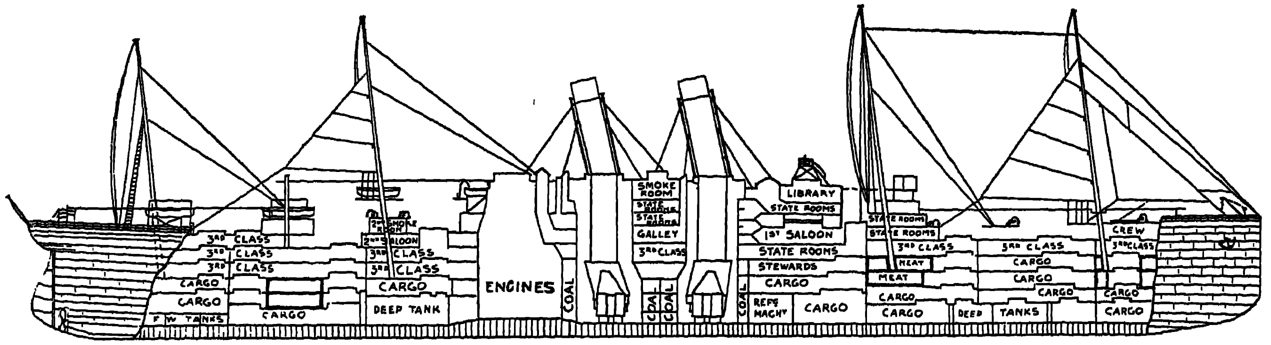

FIG. 14.—Plan of *Cedric*.

makes trips from London to the coast of Kent and thence across the Channel, is 330 ft. long, has accommodation for a large number of passengers, and obtained 22 knots with 7500 I.H.P. on trial.

Cross-Channel Steamers.—The mail service between Holyhead and Kingstown has for many years employed a number of splendid vessels, which may be taken as typical of this class. The four paddle-steamers, *Ulster*, *Munster*, *Leinster*, and *Connaught*, built in 1860 for this service, were 337 ft. long, 35 ft. broad, and 19 ft. deep; their speed was 18 knots with 6000 I.H.P. A vessel of the same type, but larger, named the *Ireland*, was added to the fleet in 1885. In 1896 and 1897 the four new twin-screw steamers were built, and received the same names as the four vessels built in 1860, which they have replaced. Their length is 360 ft., breadth 41 ft. 6 in., depth 29½ ft., and displacement 2230 tons at 14 ft. 6 in. load draught. Their sea-going speed is 23 knots. They have sleeping-berths for 238 first-class and 124 second-class passengers, and large dining and other public rooms for general accommodation. Considerable space is set apart on the main and lower decks for the mails, &c. The engines consist of two sets of triple-expansion four-cylinder engines, there being two low-pressure cylinders of equal size in each set, an arrangement which lends itself readily to the balancing of the machinery.

Atlantic Liners.—Particulars of the famous liners which have had a share in the development of the trans-Atlantic service are given in Table V., which is taken chiefly from *The Atlantic Ferry*, by A. J. Maginnis, and many more details may be found in the opening portion of the article STEAMSHIP LINES in this volume, and in the historical sketches it contains of the various lines, such as the Allan, the American, the City of Dublin, the Collins, the Cunard, the Guion, the Hamburg-American, and the White Star. Some of the most noteworthy vessels are illustrated in Figs. 15–19 (Plates III. and IV.). The *Persia* (Fig. 15) was the first iron steamer to be placed on the Atlantic service by the Cunard Company (1856). Fig. 16 is the *City of Rome*, built in 1881 at Barrow for the Inman Line, one of the most graceful vessels on the Atlantic; when first completed she was square-rigged on the three forward masts, and looked even better than she does in the illustration. The *Campania* (Fig. 17) and her sister-ship the *Lucania*, each 600 ft. long, and built in 1893 for the Cunard Company by the Fairfield Shipbuilding Company, held the record for fast passages across the Atlantic for several years. With twin-screws and triple-expansion engines they attained a speed of 23½ knots on trial with 31,050 I.H.P. On her best runs the *Lucania* crossed the Atlantic, 2823 nautical miles, in 5 days, 8 hours, 38 minutes, the mean speed being 22 knots for the run, maintained with a consumption of coal amounting to 20½ tons an hour. The second *Oceanic*, built for the White Star Line at Belfast in 1899, is shown in Fig. 18; and the *Deutschland* (Fig. 19), built at Stettin for the Hamburg-American Line, broke the

record in 1900, traversing the Atlantic from New York to the Eddystone in 5 days, 17 hours, 28 minutes, at a mean speed of 23·36 knots. In a subsequent voyage she maintained an average of 23·52 knots. A still larger vessel, the *Kaiser Wilhelm der Zweite*, launched in 1902 for the North German Lloyd, is 706½ ft. long, with a beam of 72 ft. Her gross tonnage is about 20,000, and when loaded with 5600 tons of coal her displacement will be 26,000 tons. She is intended to maintain a speed of 23½–24 knots across the Atlantic.

In recent years a remarkable development in shipbuilding has proceeded in the United States, following on the demands in connexion with the building of the modern American navy, and work of every kind of the highest class is in progress on a large scale. The Newport News Co. has built the *Siberia* and *Korea*, for the service of the Pacific Mail Co. from Hong Kong to San Francisco, which are far in advance of all previous vessels on the Pacific lines. These vessels are 572 ft. over all, 63 ft. beam, and of 18,600 tons displacement on a draught of 27 ft. Their machinery is of 18,000 I.H.P., and is capable of maintaining 18 knots ocean speed. The Philadelphia firm of Cramp and Son has turned out the American Line vessels *St Louis* and *St Paul*, which have run with great success on the New York and Southampton service; and more recently the splendid vessels *Sierra*, *Ventura*, and *Sonoma*, for the Oceanic Steamship Co., for the mail service between Sydney, New Zealand, Honolulu, and San Francisco. Their dimensions are: length 425 ft. over all, beam 50 ft., moulded depth 28 ft. 3 in., tonnage about 6000, horse-power 8000, speed 17 knots. Although these vessels are smaller than the *Siberia* and *Korea*, they are far superior to any previous vessels on the Pacific routes, excepting the *Empress of India* and other vessels on the Hong Kong and Vancouver service. They have magnificent accommodation for a large number of passengers, and are specially built so that in thirty-six hours they can be fitted up as armed cruisers for the U.S. navy. More remarkable than either of these are the vessels being built by the Eastern Shipbuilding Co. of New London for the Oriental service of the Great Northern Railway. The aim in these vessels is to carry an immense cargo at a low cost, and at the same time a considerable number of passengers with greatly improved accommodation; they are 630 ft. long, 73 ft. beam, 55 ft. depth, and when fully laden their displacement will be nearly 33,000 tons, of which about 20,000 tons may be cargo. Their speed is stated to be about 14 knots, and their cost about £500,000 per ship. With the exception of the *Celtic* and the *Cedric* of the White Star Line, these will be the largest vessels in the world.

Special Vessels.—Many vessels are built for special and exceptional purposes, and cannot be classed with either ordinary cargo or passenger vessels. Amongst these may be included dredgers, train-carrying ferry-boats, and ice-breakers. To *dredgers* a special article has been devoted (see vol. xxvii.). *Train ferries* have been in use since 1870. In 1869 Mr Scott Russell described (*Trans. Inst. Nav. Arch.*) a train ferry-boat of special construction in use on the Lake of Constance, having a length of 220 ft., a breadth over the paddle-boxes of 60 ft., and a displacement of 1600 tons; the horse-power of her machinery was 200, divided between the two paddle-wheels, each of which was driven by a pair of independent oscillating engines. The object of this steamer was to convey trains between Romanshorn, on the one side of the lake, and Friedrichshafen, on the other; she was built of iron, and was designed to have great strength combined with light draught. In 1872 train ferry-boats were introduced into Denmark to carry trains between the mainland and the islands and, later, between Denmark and Sweden. In 1883 the *Solano*, a large train ferry 406 ft. long was built by Messrs Harlan and Hollingsworth, of Wilmington, Delaware, to run between Bernicia and Porto Casta in connexion with the Central Pacific Railway. Two other interesting examples of train ferries, shown in Figs. 20 and 21 (Plate V.), were built on the Tyne by Sir W. G. Armstrong, Whitworth, and Co. Ltd., in 1895 and 1896, the former for service on the river Volga, and the latter for service on Lake Baikal in Siberia. The Volga has a rise and fall of no less than 45 feet between spring and midsummer, and the ice upon it in winter is usually 2 ft., and sometimes 3 ft., thick; thus the problem presented considerable difficulties, which were increased by the fact that the locks of the Marinsky canal system, through which all vessels bound for the Volga must pass, are of such dimensions that it was impossible for vessels of sufficient size to be got through in one piece. It was decided to use two vessels to do the work, the first to act only as an ice-breaker, and the other to act only as a train-carrier. The ice-breaker was built in two pieces, the parting being at the longitudinal middle-line plane of the vessel. This was satisfactorily carried out by means of a double longitudinal middle-line bulkhead extending the whole length of the vessel. On arrival at the canal she was divided into halves, and was joined up again after passing through the last of the locks. Her dimensions were: length 147 ft., breadth 37 ft. 6 in., and depth 16 ft. 6 in., and she was fitted with compound engines and twin screws. The ferry steamer itself (Fig. 20, Plate V.) was 252 ft. long, of 55 ft. 6 in. beam, and of 14 ft. 6 in. depth. Four lines of rails were laid upon her deck, sufficient space being provided for 24 trucks or carriages, which are shown in position in the figure. The difficulty presented by the great difference in the river level was got over by an arrangement of hydraulic hoists, placed at the bow, by which two trucks could be lifted at once to a height of 25 ft., and by having lines of rails at the landing-stages at two levels. The vessel was fitted with twin screws and compound engines, which gave her a speed of 9 knots. It was found necessary to divide her into four parts for the passage through the canal locks; the divisions were made at the longitudinal middle-line plane and athwartships at her middle. Each quarter, when apart, formed a water-tight hull, and reunion was effected while the parts were afloat.

The *Baikal Ferry* (Fig. 21, Plate V.) is employed in carrying trains across the lake in connexion with the Siberian Railway. For more than half the year the lake is frozen over to a considerable thickness, and in this case the vessel must of necessity be herself a powerful ice-breaker as well as a ferry steamer. The figure is from a photograph of a model, in which part of the side is removed in order to show the railway carriages in position. Her dimensions are: length 290 ft., beam 57 ft., draught under ordinary conditions 18 ft. 6 in., and displacement 4200 tons. The hull is closely subdivided for additional safety in case of perforation. She has three sets of triple-expansion engines, working three independent screw propellers, two placed aft, as in ordinary twin-screw ships, and one placed at the forward extremity for the purpose of disturbing the water under the ice, thus assisting the heavy cast-steel stem and armoured bow to break up the solid field-ice which the vessel has to encounter. The complete structure was first erected on the Tyne, then taken to pieces and shipped to St Petersburg; from thence its numerous parts were carried to the farthest point on the Siberian Railway, whence they were taken to their destination on sledges, and there the ship was re-erected and launched. The boilers constituted the heaviest individual pieces thus transported, as the weight of each could not be reduced below 20 tons.

Ice-breaking steamboats for securing a passage through frozen waters also date from an early period; one is spoken of as early as 1851, and several have recently been constructed for the Baltic and other parts for special purposes, instances of which have just been noticed in connexion with train ferries. The *Ermack* (Fig. 22, Plate V.), built in 1898, aims at being more effective than any previously constructed. Her dimensions are: length 305 ft., breadth 71 ft., depth to the upper deck 42 ft. 6 in., and displacement 8000 tons; her engines develop 8000 I.H.P., giving her a speed of 15 knots. Her

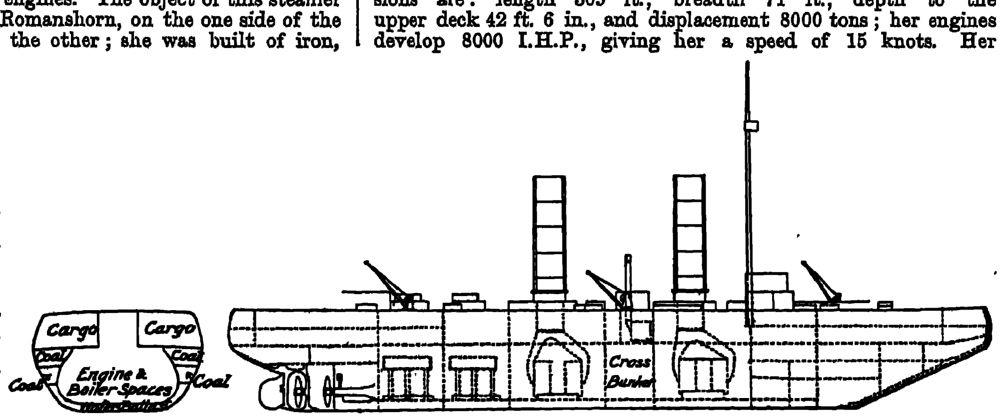

FIG. 23.—Section of *Ermack*.

general outline is shown in Fig. 23, from which it will be seen that her bow slopes upwards from below, so as to enable her to run up on to the ice and bring her weight to bear in breaking it. Her stern is so shaped as to protect the propellers as much as possible from masses of ice; and her transverse form is such that when wedged in between masses of ice she will tend rather to rise than to be depressed. She is built of steel, and is of very

great strength, the bow being specially strengthened to enable it to withstand the impact with the ice. As first constructed, she had three screws aft and one forward. The forward screw was provided with the object of sucking water by its action from under the ice, and so giving more effect to the weight of the ship; but on an experimental voyage in the Polar Sea, working through thick field-ice, the shaft of this screw became bent, and it was necessary to remove the propeller and provide temporary protection to the shaft-end. A new bow, that shown in Fig. 23, was afterwards fitted, with this forward propeller omitted. The *Ermack* made her maiden voyage in the middle of the winter of 1898–99, when she steamed through the Baltic to Kronstadt, crushing the ice with comparative ease. After this passage, during the remainder of the winter she assisted 41 steamers which were in difficulty, including the salvage of a Russian warship, which had unfortunately stranded on the island of Hogland. In the summer of 1899 she made the experimental voyage, above referred to, in the Polar Sea north of Spitsbergen, and notwithstanding her accident, continued far enough to demonstrate that she could make her way through this vast ice-field and deal with floes of the greatest thickness. An account of this vessel was given by Colonel Swan, C.B., before the Institution of Naval Architects in 1899.

War Vessels.

In the development of the modern warship during the latter half of the 19th century we shall have to deal with progress even more remarkable than that recorded for merchant ships. The adoption of iron and steel as the material for shipbuilding, and the development of the steam engine, have influenced warship construction in the same manner as they have influenced the construction of ships for the mercantile marine; but, in addition, the introduction of armour for the protection of ships, the great advances made in its manufacture, and, above all, the marvellous improvements in explosives and in the design and manufacture of guns, have almost continuously changed the conditions of naval warfare, and called for corresponding change in the design of warships. Those who are concerned in such questions may refer with advantage to an interesting comparison between the old *Victory* and a modern battleship instituted by Sir Andrew Noble in his address to the Mechanical Science Section of the British Association in 1890. Sir Andrew Noble's remarks in this connexion are the more weighty as coming from the director of the largest arsenal in the world, the works of Sir W. G. Armstrong, Whitworth, and Co., and from one whose scientific research has incalculably advanced our knowledge of artillery and explosives. Sir Andrew follows up this comparison by the following reference to the condition of things just before the Crimean war:—

"The most improved battleships of the period just anterior to the Crimean war differed from the type I have just described mainly by the addition of steam power, and for the construction of these engines the country was indebted to the great pioneers of marine engineering, such as J. Penn and Sons, Maudslay, Sons, and Field, Ravenhill, Miller, and Co., Rennie Bros., &c., not forgetting Messrs Humphreys and Tennant, whose reputation and achievements now are even more brilliant than in those earlier days. Taking the *Duke of Wellington*, completed in 1853, as the type of a first-rate just before the Crimean war, her length was 240 ft., her breadth 60 ft., her displacement 5830 tons, her indicated horse-power 1999, and her speed on the measured mile 9·89 knots. Her armament consisted of 131 guns, of which thirty-six 8-in. and 32-pdrs. were mounted on the lower deck, a similar number on the middle deck, thirty-eight 32-pdrs. on the main deck, and twenty short 32-pdrs. and one 68-pdrs. pivot gun on the upper deck. Taking the *Cæsar* and the *Hogue* as types of second- and third-rate line-of-battleships, the former, which had nearly the displacement of the *Victory*, had a length of 207 ft., a breadth of 56 ft., and a mean draught of 21. She had 1420 indicated horse-power, and her speed on the measured mile was 10·3 knots. Her armament consisted of twenty-eight 8-in. guns and sixty-two 32-pdrs., carried on her lower, main, and upper decks. The *Hogue* had a length of 184 ft., a breadth of 48 ft. 4 in., a mean draught of 22 ft. 6 in.; she had 797 indicated horse-power and a speed of $8\frac{1}{2}$ knots. Her armament consisted of two 68-pdrs. of 95 cwt., four 10-in. guns, twenty-six 8-in. guns, and twenty-eight 32-pdrs. of 50 cwt.—sixty guns in all.

"Vessels of lower rates (I refer to the screw steam frigates of the period just anterior to the Crimean war) were, both in construction and armament, so closely analogous to the line-of-battleships that I will not fatigue you by describing them, and will only allude to one other class, that of the paddle-wheel steam frigate, of which I may take the *Terrible* as a type. This vessel had a length of 226 ft., a breadth of 43 ft., a displacement of about 3000 tons, and an indicated horse-power of 1950. Her armament consisted of seven 68-pdrs. of 95 cwt., four 10-in. guns, ten 8-in. guns, and four light 32-pdrs."

The warships which existed at the beginning of the latter half of the 19th century were, with the exception of special vessels, divided roughly into three classes—ships of the line, frigates, and gun-vessels. At the present day the corresponding types are known as battleships, cruisers, and gunboats, and a fourth class has been created in the torpedo-boat and torpedo-boat destroyer. It is proposed to refer to these in the order named. (See also Navies.)

Battleships.

The destruction of the Turkish fleet at Sinope (30th November 1853) by the Russian fleet, the latter alone being armed with shell guns, and the combined experience of the British and French fleets before Sebastopol when engaging Fort Constantine, demonstrated conclusively that for ships of the line armour-protection had become essential. The French Government immediately began to build five armour-plated vessels, or batteries, as they were called, for service in the Black Sea; and eight similar vessels were begun shortly afterwards by the British Government for the same service. The British vessels did not arrive in time to take any part in the war; but three of the French batteries did, and were very favourably reported on by Admiral Bruat after an engagement with the Kinburn Forts on 17th October 1855. With the exception of these three French batteries, the whole of the fleets employed in the operations were composed of unarmoured wood ships, and a large number of them were sailing line-of-battleships. As the result of the engagement with the Kinburn Forts, the French commenced to build the first armour-plated wood frigate, *Gloire*, at Toulon in March 1858; and shortly afterwards (June 1859) the armour-plated iron frigate *Warrior* (Fig. 24) was commenced by the British Government. A number of vessels quickly followed, including, on the side of the British Government, the *Black Prince*, which was a sister ship to the *Warrior*, and four other vessels, the *Achilles*, the sister ships *Minotaur* and *Agincourt*, and the *Northumberland*. The distribution of the armour and other features of these vessels are shown in Fig. 24. The *Warrior* and *Black Prince*, which were 380 ft. long and of 9210 tons displacement, had a speed of $12\frac{3}{4}$ knots, and were originally armed with twenty-six 68-pdrs. and eight 110-pdrs. on the main deck, and two 110-pdrs. and four 40-pdrs. on the upper deck, which armament was afterwards altered to four 8-in. 9-ton guns and twenty-eight 7-in. $6\frac{1}{2}$-ton guns, all mounted on the broadside. They had a central citadel 213 ft. long, protected with $4\frac{1}{2}$-in. iron armour extending from a few feet below the water-line to the height of the upper deck. Their outline was similar to the outline of the wooden frigates of the day, and their rudder-heads and steering-gear were above water and unprotected against injury by shot and shell. In the four vessels which immediately followed, which were from 500 to 1500 tons more displacement, the overhanging bow, as will be seen from Fig. 24, was given up, bows more adapted for ramming were introduced, and some protection was afforded to the steering-gear by water-line belts of armour which extended the whole length of the vessel. In 1861 the British Government began the construction of eleven armour-clads, six of which, including the *Hector* and *Valiant*, sister ships of 6700 tons, were iron vessels, and five,

the *Caledonia*, *Royal Oak*, *Ocean*, *Prince Consort*, and *Royal Alfred*, were wooden vessels of rather over 4000 tons.

The reconstruction of the British fleet was taken in hand in earnest in 1863, when Mr (afterwards Sir) Edward J. Reed was placed at the head of the Construction Department at the Admiralty, with Messrs Barnaby, Barnes, Crossland, Morgan, and Wright—the last named (afterwards Sir James Wright) holding the position of engineer-in-chief—as his immediate assistants. Various types of vessels were devised, with arrangements of armour and dispositions of guns, to provide for the new conditions which had been introduced; and, in addition, great advance was made in the structural arrangements of ships, which up to this period had been considerably influenced by the old systems of construction in use in wooden ships. In investigating the qualities of ships, Sir Edward Reed had the good fortune to secure the co-operation and assistance of Mr William Froude, F.R.S., who had been the first to demonstrate accurately the theory upon which the behaviour of ships in a seaway depends. Mr Froude's experimental investigations on the forms of ships and kindred matters, begun in 1870 on behalf of the Admiralty and continued till his death in May 1879, had a most important bearing on the improvement of ships and on the science of naval construction generally. It is not too much to say that nearly the whole of the accurate information as to the best forms of ships and their resistance at various speeds, in the possession of naval architects to-day, is the direct result of Mr Froude's work, and that of his son, Mr R. E. Froude, F.R.S., who has continued the work since his father's death.

Sir E. J. Reed.

Among the considerations which Mr Reed had in view in the reconstruction of the navy, and which may be said to hold down to the present day, with variations dependent on the development of steam propulsion, gun attack, character of armour, and other conditions, may be enumerated the following:—(1) Steadiness of ship as a gun platform, with ample stability in all conditions of lading to enable her to keep the sea in all weathers, and sufficient stability in a partially-riddled condition to enable her to reach port in safety. (2) Protection by armour of the vitals of the ship, and of the heavy-gun positions, especially against shell fire. (3) The carrying of guns of power sufficient to penetrate the armour of any possible enemy. (4) Mounting the guns sufficiently high above the water-line to enable them to be fought in bad weather. (5) Simultaneous all-round fire, with concentration of as many guns as possible on any given point of the compass, fire in the line ahead from as great a number of guns as possible being considered of special importance. (6) Speed to overtake or get away from an enemy. (7) Manœuvring power to maintain, as far as possible, any desired position with regard to an enemy. (8) As large a radius of action as possible, coal-carrying capacity and economy of fuel being the two factors governing the radius of action and the strategical advantages dependent thereon in vessels provided with steam power alone. (9) The proper provision for the berthing of officers and crew. (10) The importance of limiting size and cost.

Objections were raised to the early armour-plated ships on the score of their unhandiness, heavy rig, exposed position of guns, &c. To meet these, Mr Reed designed a number of vessels, among which may be mentioned the *Bellerophon*, launched in 1865. She was a vessel of 7550 tons displacement, 4000 I.H.P., 14 knots speed, and was 300 ft. long, or 100 ft. less than the *Minotaur*. Her armament consisted of ten 9-in. 12-ton and five 7-in. 6½-ton guns. Her water-line was wholly protected by 6-in. armour, and she was provided with a central battery 98 ft. long, protected with armour of the same thickness. She carried a considerable spread of canvas, and she was fitted with a balanced rudder. The *Hercules*, completed in 1868, was a much more important ship than her predecessors, her dimensions being: length 325 ft., breadth 59 ft., draught 26½ ft., and her displacement 8680 tons. Her engines were of 8500 I.H.P., which gave her a speed of about 14½ knots. She had two 9-in. guns, mounted one forward and one aft on the main deck behind 6-in. armour, and eight 10-in. guns, mounted in a central battery on the main deck, four of which were mounted on revolving platforms, and could be worked from angle ports at the corners of the battery as well as from the broadside ports. Her water-line was protected by armour 9 in. thick amidships, reduced to 6 in. at her ends, and her battery was protected by 6-in. armour. She was handy under canvas, and was undoubtedly the most successful sea-going armour-clad of her day. The *Sultan*, completed in 1871, was in many respects a similar ship to the *Hercules*, but rather larger, having a displacement of 9200 tons, the same length, 2 ft. more beam, and 1 foot more draught; she attained a speed of upwards of 14 knots. Her main-deck battery carried the same guns as the main-deck battery of the *Hercules*, but the 9-in. guns at the extremities of the vessel on this deck were dispensed with, and she carried, in addition, an upper-deck battery, placed over the after-end of the main-deck battery,

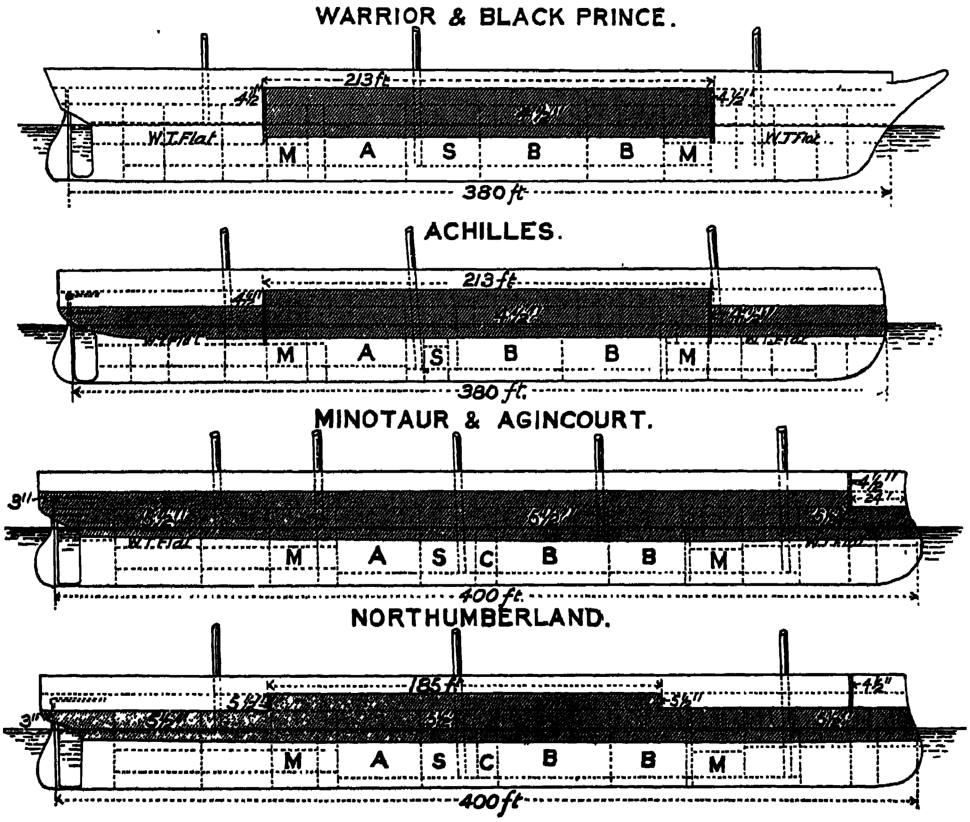

FIG. 24.—Plan of *Warrior* and *Black Prince*, *Achilles*, *Minotaur* and *Agincourt*, and *Northumberland*. A, engine-room; B, boiler-room; C, coal bunkers; M, magazines; S, shell-rooms.

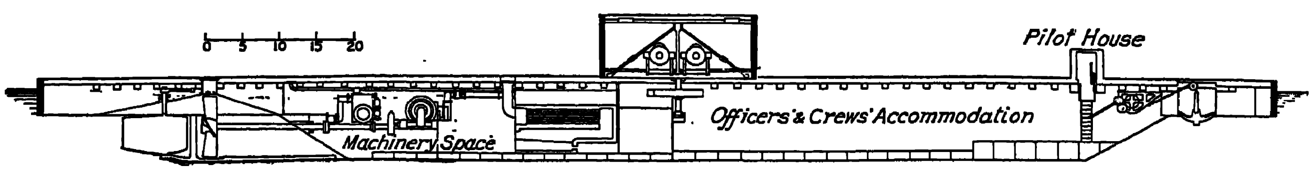
in which four 9-in. guns were carried. Both batteries were protected with 6-in. armour; elsewhere the armour was of same thickness and was disposed in a similar manner to the corresponding armour in the *Hercules*. As originally completed, the *Sultan* was a fully-rigged ship, but on her refit in 1892 her old masts were removed and a pair of military masts substituted, as shown by Fig. 25 (Plate VI.).

Turret Ships.—The first turret ship in the British navy was the *Royal Sovereign*, built of wood and launched in 1857 as a 121-gun ship of 3760 tons, and afterwards cut down and reconstructed as a turret ship, under the superintendence of Captain Cowper Coles, between 1862 and 1864. The system of mounting heavy guns on revolving turrets had been worked out in America during the war by Captain Ericsson. Captain Cowper Coles, who had designed turret ships for foreign powers, became the advocate of the turret system in Great Britain; and as the result of discussion and the pressure brought to bear by public opinion, the *Monarch*, of 8850 tons displacement, was laid down in June 1866 as a sea-going turret ship. She was launched May 1868. Her dimensions were: length 330 ft., breadth 57 ft. 6 in., and draught 26 ft.; her I.H.P. was 8000, giving her a speed of about 15 knots, and she carried a large spread of canvas. She had a complete armour belt 9 ft. 9 in. wide and 7 in. thick, reduced to 6 in. at the extremities. Above this armour belt amidships, for a length of 84 ft., she was provided with a citadel, also of 7-in. armour, which protected the bases of two revolving turrets, each protected with 10-in. armour and carrying two 12-in. guns. She also carried two 9-in. guns forward on the upper deck and one 7-in. gun aft on the main deck, all protected by armour.

The design of the *Monarch* did not satisfy Captain Coles, and he induced the Admiralty to build a turret ship of much lower freeboard, in accordance with his views. This vessel was the *Captain*, built at Birkenhead and launched in March 1869. By an unfortunate error her freeboard was even less than Captain Coles had contemplated. She was fully rigged, with tripod masts and large sail-spread; this spread of canvas, with her low freeboard and deficient stability, resulted in the terrible disaster in the Bay of Biscay, when she capsized on 6th September 1870, amongst those drowned being her designer.

A number of low-freeboard turret vessels of the *Monitor* class, without masts and sails, were built for the British navy at this time, mostly for coast defence. Amongst these, the *Cerberus* for Australia and the *Abyssinia* and *Magdala* for India were completed in 1870. The *Abyssinia* had a displacement of 2900 tons and a speed of about 9½ knots; her dimensions were: length 225 ft., beam 42 ft., draught 14½ ft., and her armament consisted of four 10-in. 18-ton guns. The other two vessels had the same armament, but were somewhat larger, being of 3340 tons displacement; and the thickness of their side armour was 8 to 6 in., against 7 to 6 in. in the *Abyssinia*. Several vessels of this type were also built for home service, including the single-turret vessels *Glatton* (Fig. 26, Plate VI.) of 4910 tons and *Hotspur* of 4010 tons, each carrying two 18-in. 25-ton guns, and the *Cyclops*, *Gorgon*, *Hecate*, and *Hydra*, each of 3560 tons and provided with two turrets carrying two 10-in. 18-ton guns. They were protected with armour from 8 to 12 in. thick, and their speed was from 10 to 12 knots. A diagram of the original *Monitor* of the U.S. navy of this period is shown (Fig. 27). She is about 170 ft. long, of low speed, armed with two powerful guns, and protected throughout with thick armour.



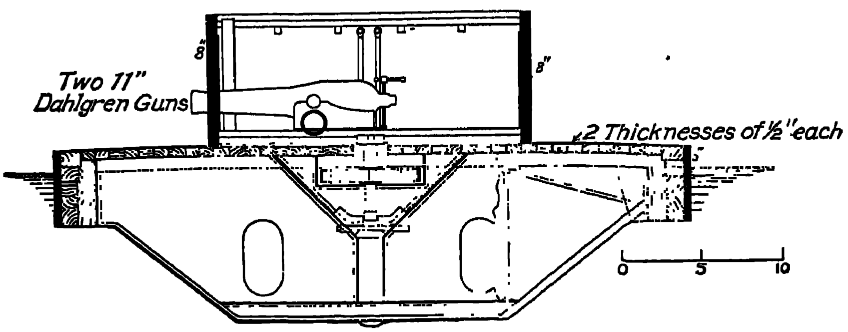


FIG. 27.—Diagram of U.S.A. *Monitor*.

The *Devastation*, commenced in 1869, represented Mr Reed's views of what a sea-going turret ship should be. Low sides were adopted, but not in combination with rigging and sails. She was the first sea-going battleship in the British navy which depended wholly on steam power for propulsion. She was 285 ft. long, 62 ft. 3 in. broad, 26 ft. mean draught, and 9060 tons displacement. Her sides, which, except right forward, rose only to a height of 4 ft. 6 in. above water, were protected with armour 12 in. thick. Her armament consisted of four 25-ton guns, mounted in pairs in two turrets, one at each end of a raised breastwork or redoubt which extended about 150 ft. along the middle of the upper deck. The guns were thus elevated to the height of some 14 ft. above the surface of the water. The turrets were protected by armour 12 in. and 14 in. thick, and the breastwork or redoubt by armour 10 in. and 12 in. thick. A forecastle extended forward from the fore-end of the breastwork at a height of 9 ft. 3 in. above the waterline; but in wake of this forecastle the side armour dropped to a height of only 4 in. above the surface of the water, at which level there was an armoured deck. She was provided with twin-screw machinery of 5600 I.H.P., which gave her a speed of 12½ knots, and she carried a large coal supply. A good idea of her general appearance may be obtained from Fig. 28 (Plate VI.). After the loss of the *Captain*, and to remove the doubt which naturally arose as to the safety of other ironclads, and particularly as to that of the *Devastation*, a special committee, including many of the highest professional and scientific authorities in the United Kingdom, was appointed to examine into the design of those vessels. Of the *Devastation* they reported that "ships of this class have stability amply sufficient to make them safe against the rolling and heaving action of the sea"; they agreed, however, in recommending a plan, which the constructors of the Admiralty had proposed, with the view of increasing her range of stability and the accommodation of the crew. This consisted in the addition of side superstructures, formed by continuing up the ship's side with light framing and plating as high as the level of the top of the breastwork, and carrying the breastwork deck over to the sides. The structures were continued aft on each side, some distance beyond the breastwork, providing two spacious wings, which added largely to the cabin accommodation.

Sir Edward Reed retired from the Admiralty a short time before the *Captain* foundered at sea. During his seven years' term of office some forty iron armour-clads of various sizes and types, besides iron cruisers and numerous other vessels, had been added to the British navy, the adoption of armour for the protection of the vital parts of ships had become established, and especially had the importance of utilizing armour in such a manner as to exclude projectiles from the region of the water-line become recognized. The change from the widely-distributed armament of the first broadside armour-clads to the highly concentrated armament of the turrets, and from the high freeboard ship with sail-power to the low freeboard turret ship without sails, had also been effected; so that when Sir Edward Reed retired in 1870, the latest type of battleship was entirely different from that which existed when he took office; and although the construction of broadside ironclads had not been discontinued, "the wooden walls" had practically ceased to exist. Sir Edward Reed was succeeded by a Council of Construction composed of his immediate assistants, with Mr Barnaby (afterwards Sir Nathaniel Barnaby) as its president; but three years later this council was dissolved, and Sir N. Barnaby was placed at the head of the Construction Department.

The sea-going qualities of the *Devastation* had success-

fully demonstrated that the battleship of the future might depend wholly on steam propulsion; and although many naval officers and others continued to hold the view that sea-going ironclads must of necessity be rigged ships, in the designs which immediately followed sail power was omitted. In the *Inflexible* (Fig. 29, Plate VI.), and the sister ships *Ajax* and *Agamemnon*, the offensive power was concentrated mainly in two pairs of heavy guns, as it was in the *Devastation* and other turret ships which preceded them; but in them the armour defence also was concentrated over a comparatively small space amidships, the unprotected ends being formed into what was called raft bodies by belts of cork, within which was placed a portion of the ship's coal, &c. Thus the buoyancy was secured by a citadel amidships which could not be penetrated, and by ends which might be riddled, but which it was contended could not be destroyed. The arrangement is shown in Fig. 30, which represents the *Agamemnon*, but which may be taken as also representing the other vessels. Sir N. Barnaby described the design of the *Inflexible* in 1874 before the Institution of Naval Architects thus:—

Sir Nathaniel Barnaby.

"Imagine a floating castle 110 ft. long and 75 ft. wide, rising 10 ft. out of the water, and having above that again two round turrets planted diagonally at its opposite corners. Imagine this castle and its turrets to be heavily plated with armour, and that each turret has within it two guns of about 80 tons each—perhaps in the course of a few years guns of twice 80 tons each. Conceive these guns to be capable of firing, all four together, at an enemy ahead or on either beam, and in pairs towards every point of the compass.

"Attached to this rectangular armoured castle, but completely submerged, every part being 6 ft. to 7 ft. under water, there is a hull of the ordinary form, with a powerful ram bow, with twin screws and a submerged rudder and helm. This compound structure is the fighting part of the ship. Seaworthiness, speed, and shapeliness would be wanting in such a structure if it had no additions to it; there is therefore an unarmoured structure lying above the submerged ship and connected with it, both before and abaft the armoured castle; and as this structure rises 20 ft. out of the water, from stem to stern, without depriving the guns of that command of the horizon already described, and as it moreover renders a flying deck unnecessary, it gets over the objections which have been raised against the low freeboard and other features in the *Devastation*, *Thunderer*, and *Fury*. These structures furnish also most luxurious accommodation for officers and seamen. The step in advance has therefore been from 14 in. of armour to 24 in., from 35-ton guns to 80-ton guns, from two guns ahead to four guns ahead, from a height of 10 ft. for working anchors to 20 ft., and this is done without an increase in cost, and with a reduction of nearly 3 ft. in draught of water, &c."

The dimensions of the *Inflexible* were: length 320 ft., beam 75 ft., mean draught 26 ft. 4 in., and displacement 11,880 tons, and her speed was 12·8 knots. The dimensions of the *Ajax* and *Agamemnon*, begun in 1876, were: length 280 ft., beam 66 ft., mean draught 24 ft. 9 in., and displacement 8660 tons. They carried four 12½-in. guns; their citadels were 104 ft. long, protected with 18-in. armour, their turrets being protected by 16-in. armour; and their speed was 12 knots. The *Edinburgh* and *Colossus*, begun three years later, were of the same type, but were built of steel and were of 9480 tons displacement. Their citadels were longer, and their speed was 14½ knots. Compound armour, adopted in these two ships for the first time, gave them a great advantage in defensive power.

The *Collingwood*, begun in 1880, was the precursor of a new type of battleship, in which the main armament consists of four heavy guns mounted in pairs on the middle line of the ship, in fixed heavily protected gun-positions called barbettes, one at each end of an armoured central citadel, this main armament being associated with a secondary armament of lighter and more rapid-firing guns mounted on the broadsides between the barbettes. This arrangement of the armament, which is clearly illustrated in Fig. 31, has continued, with small modification, to be adopted in the battleships of the British navy down to the present day. The principal features of the *Collingwood* were as follows: length 325 ft., beam 68 ft., mean draught 27 ft., displacement 9500 tons. She carried 18-in.

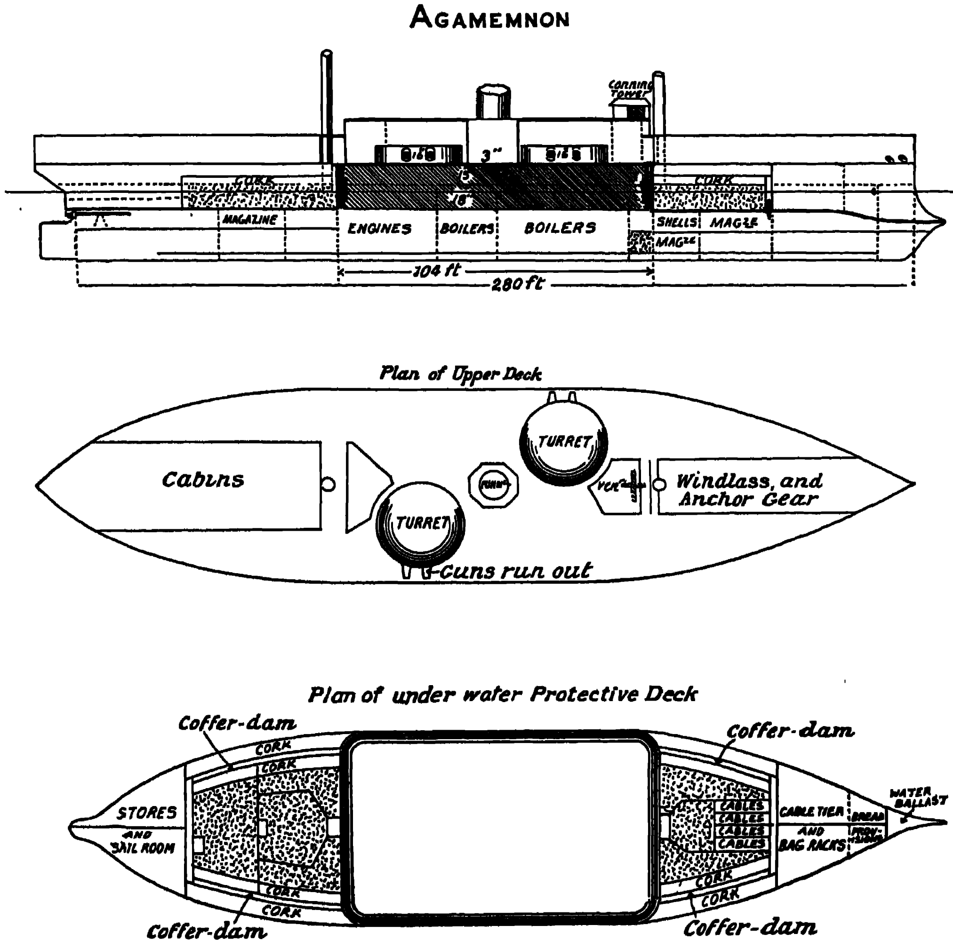

FIG. 30.—Arrangement of *Agamemnon*.

armour on her sides, 16-in. on bulkheads, 11½-in. on barbettes, and 12-in. conning towers. Her armament consisted of four 12-in. 45-ton guns, six 6-in. guns, and a number of smaller guns. Her speed was 16½ knots, and she carried 900 tons of coal, with capacity for 1200. She was followed two years later by the *Rodney*, *Howe*, *Benbow*, *Camperdown*, and *Anson*, which were of the same type, but larger. The two first named were of the same length and beam as the *Collingwood*, but of 800 tons more displacement; they carried 13½-in. guns against her 12-in., and had greater speed, namely, 16·8 knots. The last three were 5 ft. longer than the others, 6 in. broader, and were 300 tons heavier than the *Rodney* and *Howe*. The armament was the same, except in the *Benbow*, which had two 16¼-in. guns and ten 6-in. guns. These six ships constitute what is known as the *Admiral* class. A good idea of their general appearance is obtained from Fig. 32 (Plate VII.), which represents the *Camperdown*. The *Benbow* and the *Sans Pareil*, built a few years later, are the only ships in the British navy carrying 110-ton guns, the former having them in barbettes, the latter in a turret heavily armoured. The *Sans Pareil* and her

ill-fated sister the *Victoria*,[1] begun in 1885, were a departure from the *Admiral* type in both disposition of armour and armament, and have not been repeated or developed.

Among the last of the ships designed for the British navy by Sir N. Barnaby were the *Nile* (Fig. 33, Plate VII.) and *Trafalgar*, which were begun in January 1886. The disposition of armament originated in the *Collingwood* was adopted in these vessels, but the heavy guns were placed in turrets instead of in barbettes. These vessels were of rather greater displacement than the *Inflexible*, and were thus the largest ships then built for the British navy. They were 11,940 tons displacement, 345 ft. long, 73 ft. beam, and 28 ft. 10 in. mean draught; had engines of 12,000 I.H.P., and a speed of 16¾ knots. Their armour-protection (see Fig. 34) consisted of a belt 230 ft. long and 20 in. thick, with bulkheads 18 in. and 14 in. thick. Above the belt was an armoured redoubt of 18 in. compound armour 141 ft. long at the sides of the ship, with parabolic ends which enclosed the turret bases. The turrets themselves had 18-in. armour, and between the turrets was an octagonal battery of 3 in. to 5 in. of steel containing the 4·7-in. Q.F. guns. The thickness of the protective deck was 3 in. The armament consisted of four 13·5-in. 67-ton B.L. guns, six 4·7-in. Q.F., eight 6-pdrs. Q.F., twelve 3-pdrs. Q.F., besides boat guns and six torpedo tubes. They carried 900 tons of coal at normal displacement, and had stowage for 1100.

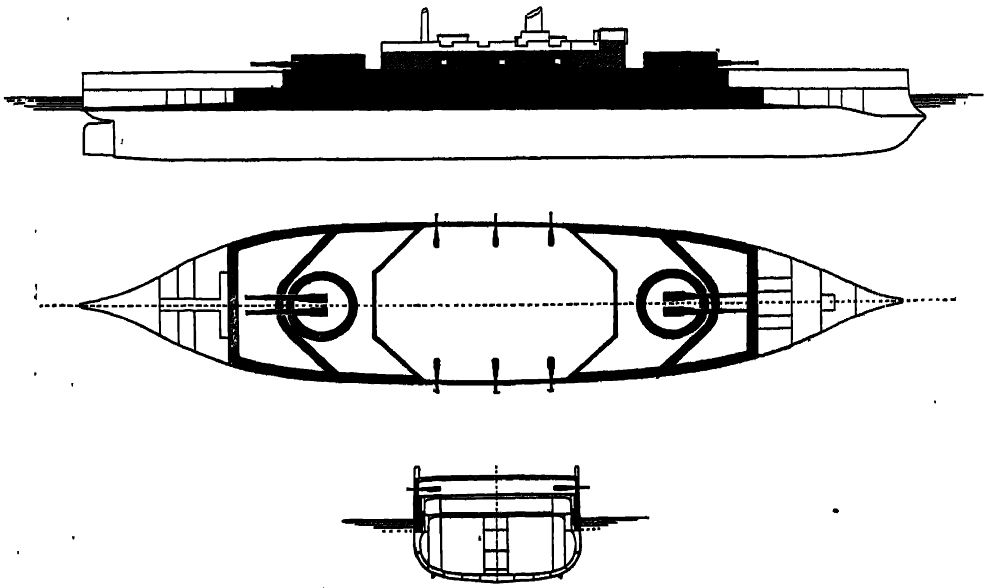

FIG. 34.—Armour of *Nile* and *Trafalgar*.

Sir Nathaniel Barnaby retired from office in 1885. During his term of office there were built for the British navy upwards of twenty armoured battleships of various classes, in addition to a much larger number of cruisers of all sizes. The fight for supremacy between the gun and the armour plate had begun in earnest when Sir N. Barnaby took office, the increased weight of projectile and penetrative power obtained by the concentration of the armament into a few heavy guns being followed by the concentration of the armour into a short belt. The concentration of guns and armour reached a limit in the *Inflexible* and her immediate successors; the later ships of Sir N. Barnaby's design carried a secondary battery of lighter guns in addition to the heavy main armament, and had much longer water-line belts. These changes, combined with the

[1] The *Victoria* was accidentally rammed by the *Camperdown* and sunk in a few minutes during the Mediterranean manœuvres of 1893.

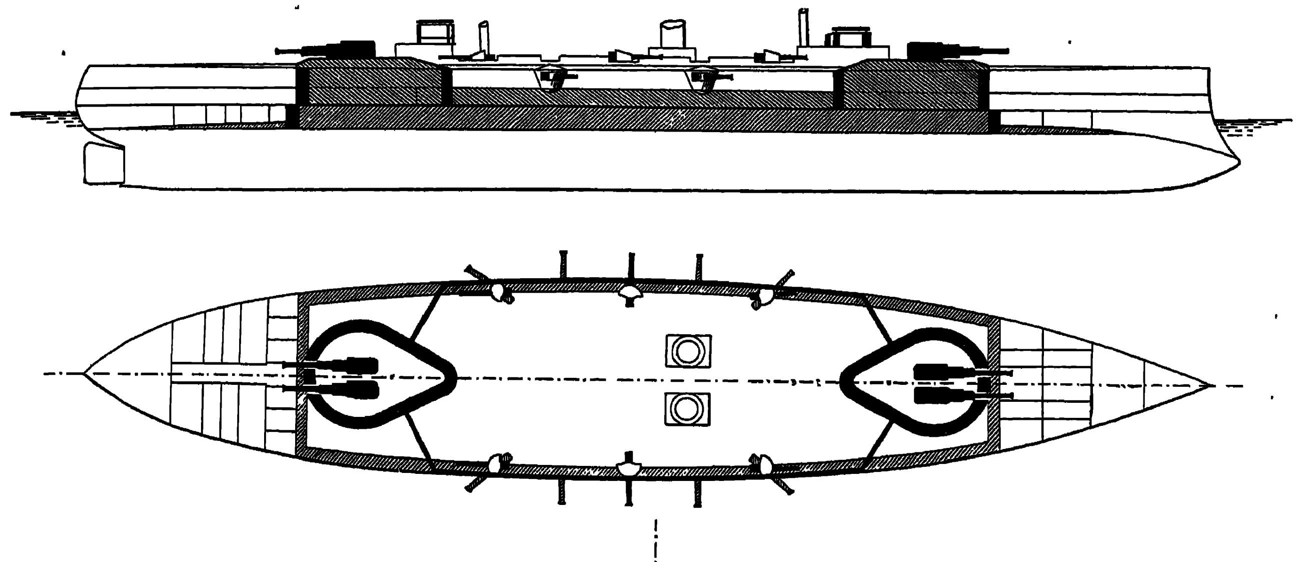
introduction of compound armour and the adoption of steel instead of iron for the building material, both of which date from this time, allowed of greater armour protection and of other advantages, including increased speed, &c. This rearrangement was first worked out in the *Collingwood*, and, as already stated, the principal features of this ship have, with few modifications, been reproduced down to the present time.

Sir William White.

Sir Nathaniel Barnaby was succeeded in October 1885 by Mr W. H. White, F.R.S. (afterwards Sir W. H. White), Dr Elgar, F.R.S., being shortly afterwards appointed Director of Dockyards, and Mr R. Sennett, Engineer-in-Chief. Dr Elgar resigned after holding office for five years, and was succeeded by Sir James Williamson, and in 1889 Mr Sennett was succeeded by Mr A. J. Durston (afterwards Sir John Durston). During Sir William White's tenure of office a very large number of ships were added to the British navy, some of which are considered below.

The *Royal Sovereign* class (see Fig. 35, Plate VII., which shows the *Royal Oak*) consisted of eight first-class battleships, built under the Naval Defence Act of 1889. With the exception of the *Hood*, which was a turret ship, the vessels of this class were all fitted with barbettes. They were of 14,150 tons displacement, were 380 ft. in length, 75 ft. beam, and 27½ ft. draught. They had 13,000 H.P. and a speed of 17½ knots. They carried 900 tons of coal at normal draught, with bunker space for 1450 tons. Fig. 36 shows the distribution of their armour, which consisted of a partial waterline belt 18 in. thick of compound armour, extending far enough forward and aft to receive the bases of the barbettes. A protective deck 3 in. thick formed a flat top to this belt, and at the level of the bottom of the belt, continued to the ends of the ship. Between the protective and main decks, extending from one barbette to the other, was an upper belt of 4 in. thickness, and above this the main deck 6-in. Q.F. guns were enclosed in casemates. The barbettes were 17 in. thick. The armament consisted of four 13½-in. B.L. guns in pairs in barbettes, ten 6-in. Q.F.—four in casemates and six in shields—sixteen 6-pdrs., twelve 3-pdrs., eight Maxims, and seven torpedo tubes. The *Royal Sovereign* established a record in quick building, having been laid down in September 1889 and launched in February 1891. The *Hood* differs from the others in having her 13½-in. guns in turrets, and the decks between the turrets and the extremities lowered to the level of the main deck in the other vessels of the class.



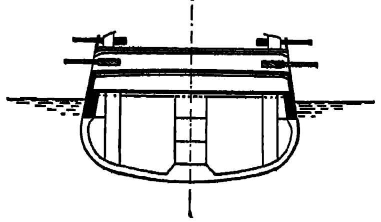


FIG. 36.—Armour of *Royal Sovereign*.

The *Centurion* (Fig. 37, Plate VII.) and *Barfleur*, begun in 1890, were smaller ships of the same general arrangement as the ships of the *Royal Sovereign* class, but with lighter armament and protection and higher speed. The 13½-in. guns of the *Royal Sovereign* are reduced to 10-in., and the 6-in. Q.F. to 4·7-in. Q.F. The belt thickness is reduced to 12 in., and the barbettes are 9 in. thick only, armour compound. The speed goes up from 17½ to 18¼ knots. The normal coal allowance was 750 tons, with stowage for 1150. Their principal dimensions were 360 ft. length, 70 ft. beam, 25 ft. 6 in. mean draught, 10,500 tons displacement. An important departure was made in these vessels in that they were sheathed and coppered. The *Renown* (Fig. 38, Plate VII.) was also sheathed and coppered; she was laid down in February 1893 and launched in May 1895. She may be described as coming between the *Royal Sovereign* and *Centurion*, but possessing the very great advantages that the adoption for the first time in the British navy of Harveyized armour conferred defensive power upon her. She was 12,350 tons displacement, length 380 ft., beam 72 ft., mean draught 25½ ft., and had an increased speed of 18½ knots. Her armament consisted of four 10-in. B.L. guns mounted in pairs in barbettes 10 in. thick, ten 6-in. Q.F. in 6-in. casemates—six on main deck, four on upper—twelve 12-pdr., and five torpedo tubes. The belt and bulkhead of this ship were of Harveyized armour 6 in. to 10 in. thick. She carried 900 tons of coal at the mean draught given above, but could stow 1200 in her bunkers.

A larger and more powerful class of battleship, known as the *Majestic* class, was begun about the same time as the *Renown*. It consisted of nine first-class battleships, the design of which constituted a great advance upon that of the *Royal Sovereign*. This advance was due mainly to the use of Harveyized armour. The 18-in. compound belt of the *Royal Sovereign* disappeared, and was replaced by a belt of about twice the breadth and 9 in. thick, this offering a resistance to penetration at least equal to the 18-in. compound belt. The protective deck was not carried flat across at the middle deck, but was above the L.W.L. at the middle line, and curved sharply down to the lower edge of the 9-in. belt, forming a strong arched roof to the vitals of the ship, to keep out any fragments of large shell which might come through the belt and burst; it was 2½ in. thick on the flat and 4 in. on the slopes. The 13½-in. guns of the *Royal Sovereign* were replaced by lighter but more powerful 12-in. wire-wound B.L. guns, disposed in the same general manner in barbettes 14 in. thick. The *Majestic* class carried two more 6-in. Q.F. guns, and all the twelve were in casemates 6 in. thick. There were sixteen 12-pdrs., besides smaller guns and five torpedo tubes. The speed was the same as *Royal Sovereign* class, and the coal carried 900 tons, with space for 2000 tons. The ships were of 14,900 tons displacement, 390 ft. long, 75 ft. beam, 27 ft. mean draught. The *Hannibal*, shown in Fig. 39 (Plate VIII.), is one of this class.

The *Formidable* and *London* classes, under construction in 1903, differ very slightly from each other, and for all practical purposes may be taken as identical, the main difference being in a rearrangement of the armour protection to the bow in the later ships (*London*). The former class consists of the three battleships *Formidable*, *Irresistible*, and *Implacable*, and the latter of the five battleships *London*, *Bulwark*, *Venerable*, *Queen*, and *Prince of Wales*. These classes represent a development of the *Majestic*

class, being 400 ft. long, 75 ft. beam, 26 ft. 9 in. draught, and 15,000 tons displacement, the belt being of the same general thickness and extent as in the *Majestic*, but of Krupp steel, and protection is given to the bow by 2-in. side-plating. In the *Formidable* the protective deck proper is formed as in the *Majestic*, but is thinner, being 2 in. to 3 in. thick, and a second protective deck, 1 in. thick, is formed at the main deck, giving a flat top to the box formed by the side belt. In the *London* class (Fig. 40, Plate VIII.) the lower protective deck is thinner and the upper one thicker than in the *Formidable* class, the belt protection being extended forward by thinner material, tapering to 2 in. at the bow, and the forward transverse armour bulkhead being omitted. The 12-in. guns in both classes are longer and heavier than in the ships of the *Majestic* class, and are in barbettes 12 in. thick; in addition, there are twelve 6-in. Q.F. guns—all in casemates—sixteen 12-pdrs., and four torpedo tubes. These eight battleships are each provided with 20 Belleville boilers, develop 15,000 H.P., and have a speed of 18 knots. They carry 900 tons of coal at their normal displacement, and have bunker space for 2200 tons.

The line of development, as traced above, may be taken to begin with the *Collingwood* and to run through the *Admiral* class, the *Nile* and *Trafalgar*, the *Royal Sovereign* class, the *Majestic* class, and the *Formidable* class, to the *London* class, which may be regarded as the most powerful type of warship yet constructed for the British navy.[1] Branching off from this line, at a time when battleships became much heavier (the *Royal Sovereign* class were of 2200 tons more displacement than the *Nile* and *Trafalgar*), we find a series of smaller, faster, and more lightly armed and armoured battleships than the series terminating with the *London* class. These began with the *Barfleur* and *Centurion*, which, though contemporary with the *Royal Sovereign* class, were of 1440 tons less displacement; they were followed by the *Renown*, the *Canopus* class, and the *Duncan* class. The last-named vessels now claim our attention.

The six ships of the *Canopus* class may be regarded as a development of the *Renown*. Begun in 1896, they are 12,950 tons in displacement, 390 ft. long, 74 ft. beam, and 26 ft. draught. They have a 6-in. Harveyized belt, 14 ft. broad and 195 ft. long; two protective decks (anticipating the *Formidable* in this respect); and 12-in. barbettes, carrying four wire-wound 12-in. guns, against the *Renown's* 10-in. They also carry twelve 6-in. guns in 5-in. casemates, ten 12-pdrs., a number of smaller and machine guns, and four submerged torpedo tubes. They were the first battleships of the British navy to be fitted with water-tube boilers; they have 20 Bellevilles, develop 13,500 H.P., and have a speed of 18¼ knots. They carry 1000 tons of coal at normal load, and have bunkers for 2300 tons. The ships of the *Duncan* class are longer and larger than those of the *Canopus* class. They were begun in July 1899, are of 14,000 tons displacement, 405 ft. long, 75 ft. 6 in. beam, 26 ft. 6 in. draught. They have a belt of Krupp steel, 7 in. thick amidships, tapering to 3 in. at bow, and two protective decks, as in the *Canopus*; they have two barbettes, 11 in. thick, with four 12-in. guns, and carry twelve 6-in. Q.F. guns in 6-in. casemates on the main and upper decks; also a number of smaller guns and four submerged torpedo tubes. They are provided with 24 Belleville boilers, will develop 18,000 H.P., and attain a speed of 19 knots. Their normal coal supply will be 900 tons, and they will have bunker capacity for 2000 tons. Six of these ships were under construction in 1902. In external appearance the *Canopus* and *Duncan* classes closely resemble the ships of the *London* class.

It will be seen that the advance in the two series of ships described above has been one of steady growth in size, power, and speed; and the scheme of building such a number of ships of each class as to form a powerful squadron of exactly similar ships has been given effect to in a large degree.

The principal changes that have conduced to the steady and rapid development of the battleship type since 1885 are:—(1) The successive improvements in armour by the introduction of the Harvey and Krupp processes, which have enabled either a saving of weight to be effected for the same degree of protection, or a greater degree of protection to be provided for the same weight. The choice has been principally in the direction of the latter alternative; the belt has been extended longitudinally and upward, shielding a greater portion of the hull and giving increased protection to the stability and to the secondary armament of the vessel. (2) Improvements in guns and explosives, by which more effective gun-fire has been obtained with guns of smaller calibre and decreased weight than those previously in use. The growth in importance of the secondary armament of quick-firing guns has exercised great influence on the development of the modern battleship. (3) Improvements in machinery. The adoption of higher steam pressures, lighter and faster-running machinery, and of water-tube boilers have effected great savings in weight for a given power, and enabled increased speed to be obtained in successive ships. Sir William White retired from the British Admiralty in February 1902, and was succeeded by Mr Philip Watts, F.R.S.

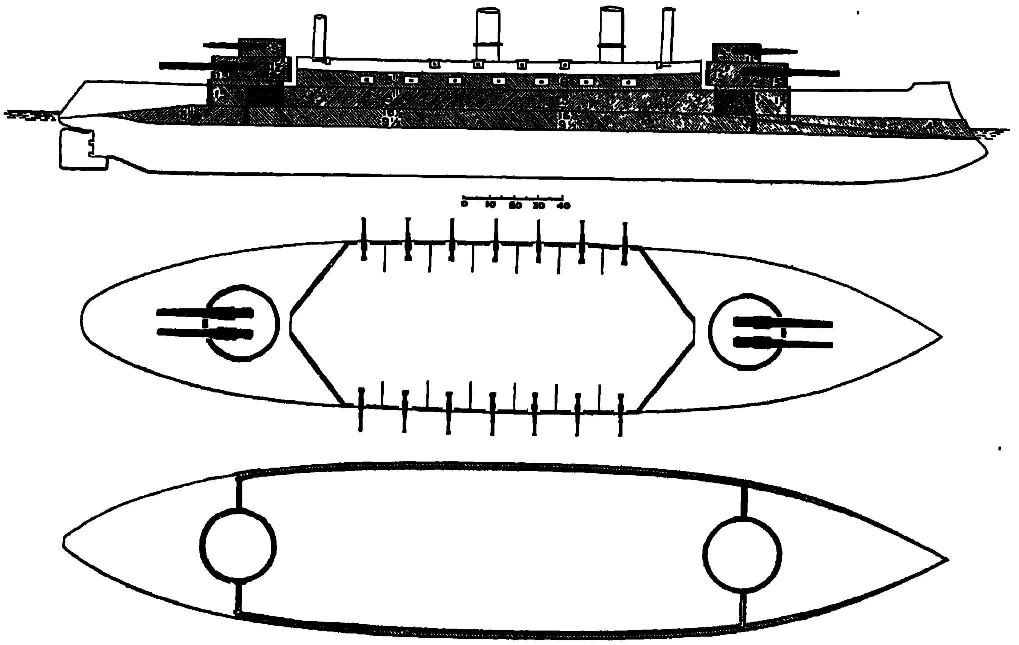

FIG. 41.—U.S. Battleship *Kearsarge*.

United States of America.—Fig. 41 shows the main features of the United States battleships *Kearsarge* and *Kentucky*. Their principal dimensions are: length 368 ft., beam 72 ft., mean draught 23 ft. 6 in., displacement 11,525 tons. They carry four 13-in. guns in turrets 15 in. thick, four 8-in. guns in turrets 9 in. thick, fourteen 5-in. Q.F. guns, twenty-seven smaller guns,

[1] In 1902 orders were placed for five battleships from Sir William White's design, to be called the *King Edward VII.* class, which are larger and more powerful than the *London*, being of 16,350 tons displacement, and carrying four 12-in. and four 9·2-in. guns in gun-houses on the upper deck, with ten 6-in. Q.F. guns in an armoured main-deck battery.

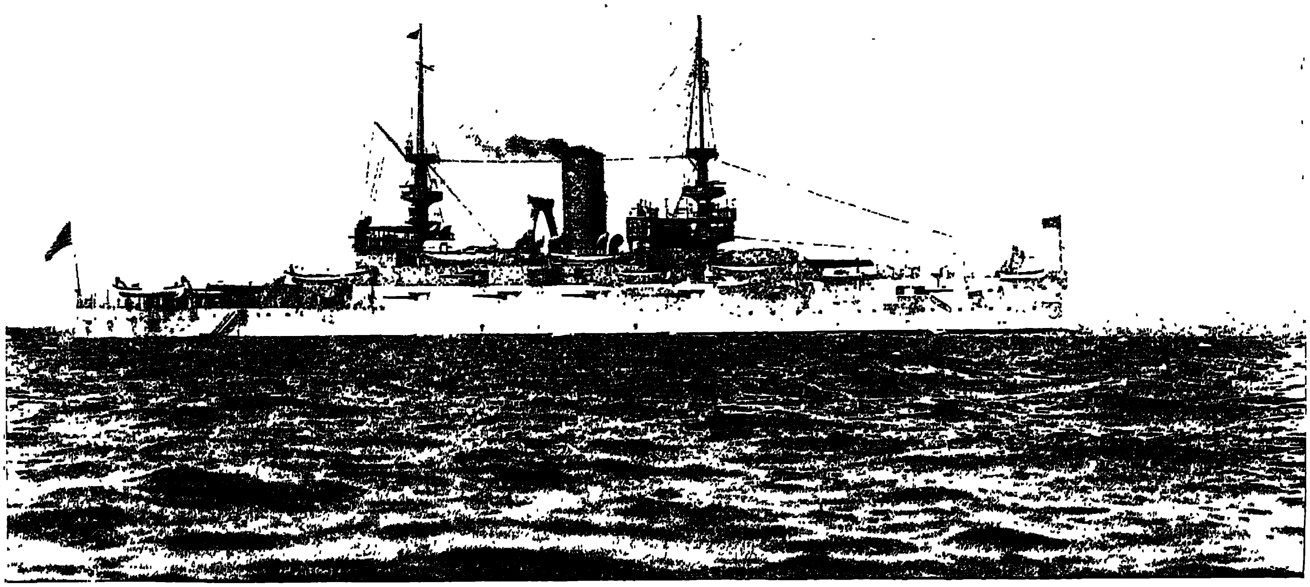

Fig. 43.—U.S.A. *Illinois.*

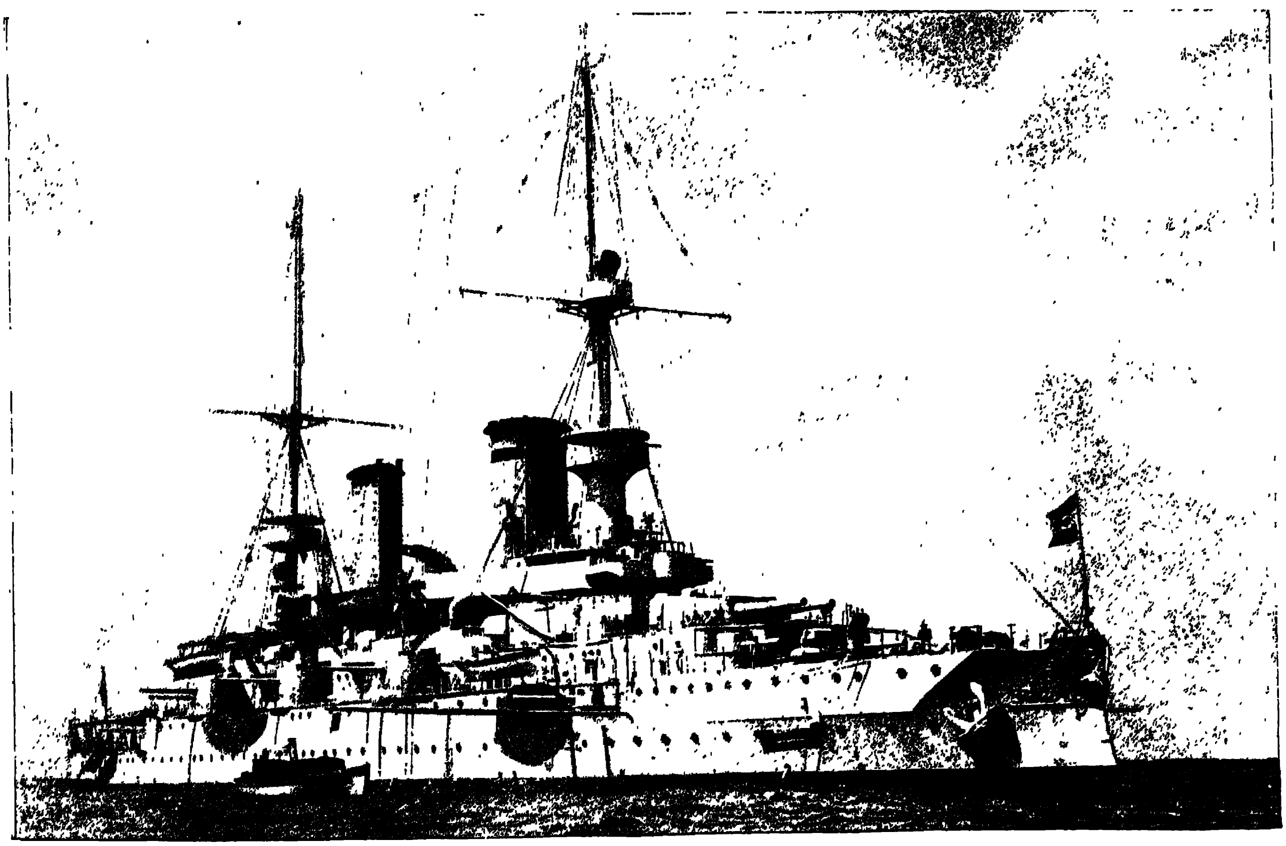

Fig. 44.—German *Kaiser Frederick III.*

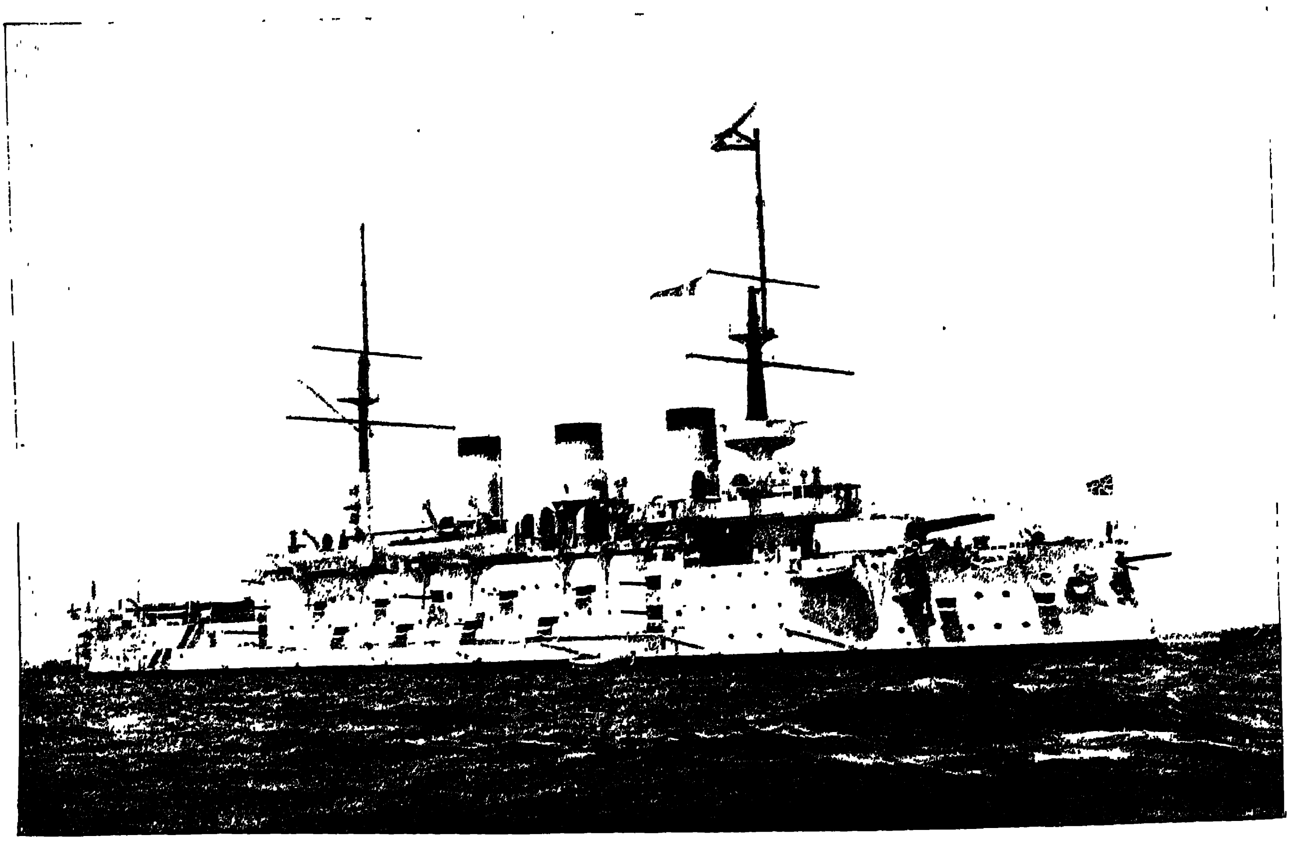

FIG. 46.—Russian *Pobyeda.*

and four torpedo tubes; and at the above displacement they carry 410 tons of coal, but can stow 1200. Their speed is 16 knots. They are worthy of special mention on account of the novelty introduced in them of the double-storeyed turret, two of which arrangements are provided in these ships, one forward and one aft. In this arrangement a second turret is superposed or built on the first, the structure so formed turning as a whole; a pair of 8-in. guns is mounted in the upper turret, and a pair of 13-in. guns in the lower. A later example of American design is furnished by the five first-class battleships of the *Georgia* class (Fig. 42), building in 1902, which have a displacement of nearly 15,000 tons, length 435 ft., beam 76 ft. 3 in., and a mean draught of 23 ft. 9 in; they have a complete water-line belt of Krupp armour, from 11 in. to 8 in. thick, tapering to 4 in. at the bow; above this belt there is a belt of lighter armour, 6 in. thick and 245 ft. long, forming a battery for the 6-in. Q.F. guns, which extends to the upper deck; there are also four turrets—two large double-storeyed turrets, as in the *Kentucky*, placed one forward and one aft, and two smaller turrets, placed on each side forward. The larger turrets carry each a pair of 12-in. guns and a pair of 8-in. guns, and are protected by a maximum thickness of 11-in. armour, and the smaller carry each a pair of 8-in. guns and are protected by 6½ in. armour. In addition to the four 12-in. and eight 8-in. guns thus disposed, there are also twelve 6-in. guns on the main deck and some forty-two smaller guns. These ships will develop 19,000 I.H.P. and have a speed of 19 knots. They will carry 900 tons of coal at normal displacement, and have capacity for stowing 1900 tons. The battleships which came between the *Kentucky* and the *Georgia* classes (*Alabama*, *Illinois* (Fig. 43, Plate IX.), *Wisconsin*, *Maine*, *Missouri*, and *Ohio*) had not the double-storeyed turrets, and it is understood that in the new and still larger class of battleships now to be proceeded with (*Pennsylvania* class) this feature will not be reproduced.

France.—The latest and largest battleship in the French navy is the *Suffren*, commenced in 1899. Her displacement is 12,728 tons, length 410 ft., beam 70 ft., and draught 27 ft. 6 in. She has a complete water-line belt of Harveyized steel armour of 11¾ in. maximum thickness, and above this, up to the main deck, similar armour, 5 in. thick, extending from the after turret to the bow; she has also a short armoured battery on the main deck which encloses the funnel uptakes. There are eight turrets on her upper deck—one forward and one aft, each carrying two 12-in. guns, and six arranged three on each broadside, each carrying a 6·4-in. gun. The armour of the larger turrets is of the same thickness as the armour belt, namely, 11¾ in., and that of the smaller turrets 5 in. She mounts eight 3·9-in. guns on the superstructure, and also has twenty-two smaller guns and four torpedo tubes, of which two are submerged. She has triple screws, engines of 16,000 I.H.P., and a speed of 18 knots.

The *République* and *Patrie*, examples of the latest French design, have a displacement of 14,865 tons, and are of 439 ft. length, 79 ft. 6 in. beam, and 27 ft. 6 in. extreme draught. They have three screws, develop 17,500 H.P., and are stated to be 18-knot ships, though if the power is realized the speed ought to be considerably more. They carry four 12-in. B.L. guns in pairs in turrets on the middle line, as in the British ships, twelve 6·4-in. Q.F. guns in pairs in turrets on the upper deck, six additional 6·4-in. Q.F. guns in casemates on main deck, twenty-six 3-pdrs., three above-water and two submerged torpedo tubes. There is a complete water-line belt of a maximum thickness of 12 in., the bow is protected by 4 in. and there is a partial 4-in. belt above the 12-in. belt. The protective deck is 4 in. on the slopes and the armour of the main turrets is 12½ in. thick, the whole armour being of Harvey quality.

Germany.—The latest battleships completed for the German navy are the five first-class battleships of the *Kaiser* class, the last of which, the *Kaiser Friedrich III.* (Fig. 44, Plate IX.), was finished in 1900. They have a displacement of 10,900 tons, a length of 377 ft., a beam of 66 ft. 10 in., and a draught of 25 ft. 9 in.; their engines are of 13,000 I.H.P. and their speed is 18 knots. They have belts of Krupp steel extending from the after barbette to the stem, with a maximum thickness of 12 in., tapering to 6 in. at the bow; there is no side armour above this belt. The main armament consists of four 9·4-in. guns, placed in pairs in barbettes, one forward and one aft, protected by 10-in. armour. On the main deck they have four 5·9-in. Q.F. guns in 6-in. armoured casemates, two on each side; and on the upper deck they have eight similar guns, protected in like manner, and six others in turrets—three each side; in all, eighteen 5·9-in. guns, besides twelve 3·5-in. and smaller guns. There are five vessels of the *Wittelsbach* class being built; these represent a development of the *Kaiser Friedrich III.* The *Wittelsbachs* are about 700 tons more displacement, are 15 ft. longer and 1½ ft. more beam, but are of shallower draught. They have 15,000 H.P. and a speed of 19 knots, or a knot more than their predecessors. Their armament is the same, but the 9·4-in. guns are better protected. The main armour belt is somewhat longer, but in other respects the thicknesses and general disposition of the protection are similar to the *Kaiser Friedrich III.* class.

Japan.—In 1902 the most recent Japanese battleships were the four ships of the *Hatsuse* class, built in Great Britain, of which the *Hatsuse* herself (Fig. 45, Plate X.), built at Elswick, may be taken as a representative in her main features. The displacement is 15,000 tons, length 400 ft., beam 75 ft. 6 in., mean draught 27 ft. The I.H.P. is 15,000, giving a speed of 18 knots. The armour-belt extends the full length of the ship at the water-line, and has a maximum thickness of 9 in. Between the top of this belt and the main deck, for a length of some 220 ft., is an upper belt 6 in. thick, which is continued by oblique bulkheads to the sides of the heavy-gun barbettes. The barbettes themselves, which are two in number, one forward and one aft, have armour 14 in. thick, and the conning-tower also is 14 in. thick. Krupp armour is used throughout. The armament consists of four 12-in. 49-ton B.L. guns, two mounted in each barbette and loading in any position; fourteen 6-in. Q.F. guns, all in 6-in. casemates, eight on the main deck and six on the upper deck; and twenty 12-pdrs., besides smaller guns and four submerged torpedo tubes. The *Mikasa*, building at Barrow in 1902, is a slight modification of the *Hatsuse* class design, being 200 tons heavier and 6 in. more in draught. The principal difference is that the eight 6-in. Q.F. guns on the main deck are increased to ten, and instead of being in separate casemates are in a 6-in. side-armoured central battery, screened from each other by 2-in. divisional bulkheads side and rear. The total number of 6-in. guns carried, however, is the same.

Russia.—The Russian battleship *Pobyeda* (Fig. 46, Plate X.) is of the lightly armed and high-speed type which are sometimes spoken of as "Intermediates," coming, as they do, midway between the heavy first-class battleship and the armoured cruiser. Her principal dimensions are: length 436 ft., beam 71½ ft., draught 27¼ ft., and displacement 12,670 tons. She has engines of 15,000 H.P. and a nominal speed of 19¼ knots, carries an armament of four 10-in. guns, mounted in pairs in turrets on the middle line forward and aft; eleven 6-in. guns, distributed five on each broadside and one in the extreme bow of the vessel; twenty 3-in. guns and twenty-six smaller pieces; and six torpedo tubes. She is protected by a complete water-line belt of Krupp armour, 9 in. thick amidships, tapering to 4 in. at the ends, reinforced by a protective deck 2¾ in.

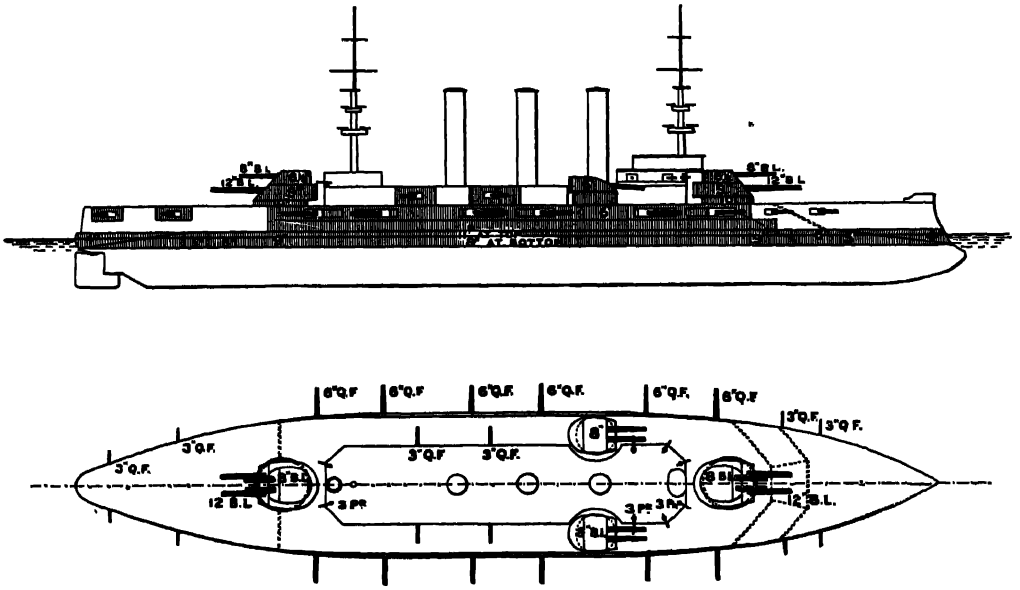

FIG. 42.—Gun and Armour Plan, *Georgia* Class (*Georgia*, *Nebraska*, *New Jersey*, *Rhode Island*, and *Virginia*).

TABLE VI.—*Development of some of the Leading Features of Armoured Battleships from 1860 to 1900.*

thick. Above the belt, for a length of 185 ft. amidships, is a lighter belt of 5-in. Krupp armour, protecting the bases of the 6-in. guns, and terminated by transverse bulkheads. The 10-in. gun turrets are 10 in. thick, and the 6-in. guns are protected by casemates 5 in. thick. This vessel carries 30 Belleville boilers, and has storage for 2000 tons of coal. The disposition of her guns and the other main features of the vessel are readily seen in the figure. In 1902 the latest completed battleship for the Russian navy was the *Retvizan*, which was built at Cramp's, U.S.A. She is of 12,700 tons displacement, 376 ft. long, 72¼ ft. beam, and 26 ft. draught. She has four 12-in. B.L. guns in pairs in turrets, twelve 6-in. Q.F. guns in 5-in. casemates, twenty 12-pdrs., and twenty-eight smaller guns, besides four submerged and two above-water torpedo tubes. She is protected by a water-line belt extending from the after turret to the stem, and tapering in thickness from 9 in. to 2 in. Above this is a complete belt of 6 in. maximum thickness, and the main armament is protected by turrets 10 in. thick. She has 16,000 H.P. and a speed of 18 knots, and has stowage for 2000 tons of coal.

Italy has undertaken the building of three new battleships, two of which are already under construction. They are designated the *Vittorio Emanuele III.* class, and have a displacement of about 12,500 tons, a length of 435 ft., a beam of 75 ft. 6 in., and a draught of 25 ft. 7 in. They have twin screws and 19,000 I.H.P., giving them 21½ to 22 knots speed; they have partial water-line belts of Harveyized steel 9¾ in. thick, and a 1½-in. protective deck; the gun positions are protected by 8-in. armour. The armament consists of two 12-in. B.L. guns, twelve 8-in. B.L. guns, twelve 3-in. Q.F., with twelve smaller guns and four torpedo tubes. The 12-in. guns are mounted singly in middle-line turrets, one forward and the other aft, the aftermost gun being a deck lower than the foremost gun; and the 8-in. guns are mounted in pairs in turrets, of which there are three on each broadside between the 12-in. turrets, the amidship one each side being at the same level as the forward 12-in. gun, and the others at the same level as the after 12-in. gun. Although classed as battleships and having a very powerful armament, this type of ship aims at a speed little short of the armoured cruiser class of other navies.

Norway.—Fig. 47, Plate VIII. shows the completed Norwegian armour-clad *Norge* on her trial trip. This vessel and her sister the *Eidsvold*, with their predecessors *Harald Haarfagre* and *Tordenskjold*, were built at Elswick for the royal Norwegian navy, and completed in 1900. They have a displacement of 3850 tons, length 290 ft., beam 50 ft. 6 in., draught 16 ft. 6 in., and with twin-screw engines of 4500 horse-power have attained 16½ knots speed. They are heavily armed with two 8-in. B.L. guns in armoured gun-houses, one at each end of the vessel; six 6-in. Q.F. guns, four mounted in 5-in. nickel steel casemates and two in the open, with strong shields; eight 12-pdrs. and six 3-pdrs.; and two submerged torpedo tubes. The water-line is protected with 6-in. Krupp armour over a length of 170 ft., and bulkheads of the same thickness are provided at each end of the belt. These ships represent a class of vessels of small size which are well protected, heavily armed, and have a fair speed, which would prove formidable opponents to many larger armoured ships, and which are especially useful for coast-defence purposes.

Table VI. shows the development of the leading features of armoured battleships from the time of the *Warrior* to 1902. The particulars, it will be seen, are in a tabulated form, arranged in order of the date of launch, and to most of the ships therein mentioned reference will be found in the preceding pages.

Cruisers.

The cruiser type was primarily intended to co-operate with armour-clad fleets, in the same manner as sailing frigates did with fleets of sailing line-of-battleships, and the earliest cruisers were modelled directly upon the frigates which preceded them, the differences between the two being those incidental to the use of steam power and to the substitution of iron for wood as the building material. As steam propulsion grew in favour, engines of greater power were provided, and the rig and sail-spread were reduced till at the present day they have almost entirely disappeared. When the final adoption of iron led to the remodelling of the details of construction by Sir E. J. Reed, the new system of construction was applied to the cruisers of the day, but no attempt was made till much later to give these cruisers any protection, nor was the question of their armament given the importance which it afterwards came to have.

Lord Armstrong was one of the first to recognize the importance of developing this class of vessel. He considered the essential features of a cruiser to be high speed, protection without the use of side armour, a powerful armament, and minimum size and cost; and his views were adopted by the Elswick firm in a large number of cruisers for foreign Powers down to the introduction of high explosives, when side armour was advocated in place of, or in addition to, the armour deck. The cruisers built for the British navy prior to 1880—of which the principal were such vessels as the *Inconstant* (Fig. 48, Plate XI.), of 5780 tons (1866); the *Active*, of 3080 tons (1867); the *Raleigh*, of 5200 tons (1871); and the faster despatch vessels *Iris* and *Mercury* (Fig. 49, Plate XI.), of 3730 tons (1875)—had been almost entirely unprotected; and although the *Comus* and *Leander* classes (see Fig. 50, Plate XI., and particulars in Table VII.) had been given a partial protective deck, the Elswick-built *Esmeralda* (1883) (see Fig. 51, Plate XI.) may be quoted as the first vessel in which the important features of a complete protective deck and good protection to the guns were combined with high speed and a powerful armament. On the other hand, the *Impérieuse* and *Warspite* (Fig. 52, Plate XII.), completed in 1881, of much greater displacement than the *Esmeralda*, were provided with a partial belt of 10-in. compound armour in combination with a protective deck. Thus the necessity for protecting cruisers led to the introduction of two types—the "protected" cruiser, of which the *Esmeralda* may be taken as the pioneer, and the "armoured" cruiser, of which the *Impérieuse* and *Warspite* are early representatives; but while in the British navy the "protected" cruiser type was repeated and developed, the "armoured" type was discontinued, and with the exception of the *Orlando* class (Fig. 53, Plate XII.), built shortly afterwards, the whole of the cruisers built for the British navy for another fifteen years were of the "protected" type. In France and Russia, however, the armoured cruiser continued in favour, the *Dupuy de Lôme* of 1890, for the former, and the *Rurik* of 1892, for the latter, being vessels of this type (see Table VII.).

The reintroduction of side armour in British-built cruisers came about 1895, when, it should be observed, the improvement of armour by the development of the Harvey and subsequently Krupp processes of manufacture enabled more efficient protection to be provided in this way with a much thinner belt than had previously been possible. The Elswick cruiser *Esmeralda* (second), built for the Chilian Government in 1895, was one of the first in which the use of side armour was revived. She was followed by other vessels of the armoured type built by the same firm for the Chilian and Japanese navies. In 1898 the *Cressy* class (Fig. 54, Plate XII.) was begun for the British navy, and since this date all cruisers of 10,000 tons and above for the British navy have been provided with side armour.

In the United States the adoption of armour belts of the new material for cruisers came somewhat earlier than it did in the British navy, the *Brooklyn* (Fig. 55, Plate XII.), built in 1895 (see Table VII.), being so protected; and the development of the type has been similar to its development in Great Britain, the tendency being to go to larger displacements, in order to provide greater protection and heavier armaments, with each new class of vessel. Indeed, the first-class armoured cruiser of the present day might be described as a high-speed battleship with a light primary armament.

Coming to more detailed descriptions of existing ships, we find in the British navy, as might be expected, that the demand for vessels to meet the varied and diverse requirements that necessarily arise in a fleet of such magnitude has led to the production of a number of classes, each adapted to their special duties. They may

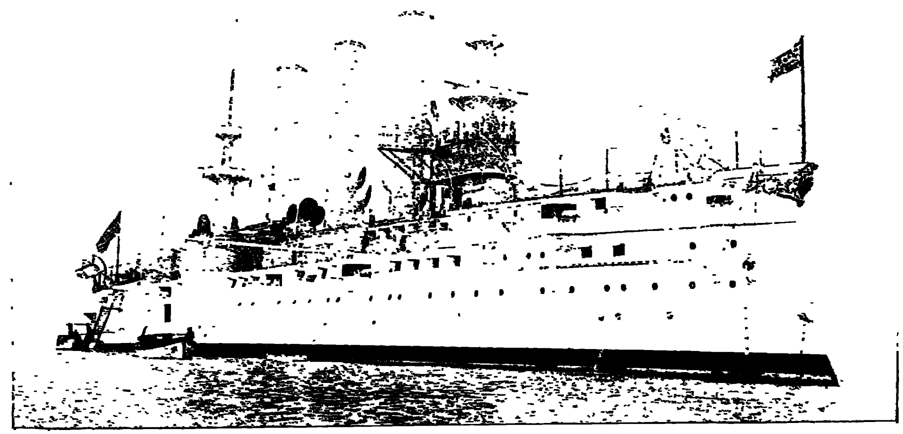

Fig. 55.—U.S.A. *Brooklyn.*

be classified as (1) unprotected cruisers; (2) protected cruisers of first, second, and third classes; and (3) armoured cruisers. Unprotected cruisers have neither side armour nor other protection against loss of buoyancy from injury by shot and shell. Protected cruisers have no side or vertical armour, but they have horizontal armour decks with strong sloping sides in the vicinity of the water, upon which coal is carried in minutely divided bunker compartments. Armoured cruisers have side or vertical armour.

Each of these classes includes a number of groups of sister ships, but we shall confine ourselves to a brief description of the main features of a representative ship in a few of the most important groups comprising each of the classes defined above.

The protected cruiser of medium displacement affords a convenient starting-point, as it so happens that the latest vessels of this type are of about the same displacement as the largest first-class cruisers of thirty years before, and a comparison of representative ships of these classes illustrates the great advances made in thirty years in ships of approximately the same size; while a further comparison of these second-class cruisers (as the vessels of medium displacement are styled) with the first-class protected cruisers and the armoured cruisers of the present day shows the growth in size and power of the largest units of the cruiser type during the same period. It should, however, be noted that while the most recent second-class cruisers are of such a displacement (5600 tons) as to allow of this comparison being made, the great bulk of the vessels of this class are smaller, particularly those which have been in service for some years. Thus the *Mersey* (Fig. 56, Plate XIII.) is an example of a vessel of this class which has seen considerable service. Begun in 1883, her principal dimensions are: length 300 ft., beam 46 ft., mean draught about 20 ft., and displacement 4050 tons. Protection to the vitals of the ship is provided for by means of a protective deck a little above the level of the water-line, 2 to 3 in. in thickness, in combination with a system of coal-stowage in bunkers along the water-line. She carries two 8-in. and ten 6-in. B.L. guns and four torpedo tubes. Her horse-power is 6000 (forced draught) and speed 17·3 knots, and she carries 750 tons of coal at normal draught, with capacity for 900 tons. The *Astræa* (Fig. 57, Plate XIII.), begun in 1890, may be taken as representing the average of the various modern vessels classified as second-class cruisers. She is built of steel, sheathed and coppered, is 320 ft. long, 49 ft. 6 in. beam, 21 ft. 6 in. mean draught and 4360 tons displacement, and carries two 6-in. Q.F. guns and eight 4·7-in. Q.F. guns, all on the upper deck and protected by shields, together with four torpedo tubes. She is protected by a steel deck 1 in. to 2 in. thick, and the engine cylinders, which project through this deck, are shielded by 5-in. sloping coamings. The coal bunkers in the neighbourhood of the water-line are minutely subdivided, and the stowage is arranged so as to make full use of the coal protection. Her engines develop 9000 H.P. (under forced draught) and her speed is 19·3 knots. Her coal stowage is 1000 tons.

Second-class cruisers.

The *Hermes* (Fig. 58, Plate XIV.) represented in 1902 the latest type of second-class cruiser added to the Royal Navy. She is 350 ft. long, 54 ft. beam, 20 ft. 6 in. mean draught, and 5600 tons displacement. She presents a striking contrast compared with the *Inconstant* (Fig. 48), built in 1866, of almost the same displacement. The *Inconstant* was fully rigged, and sailed almost as fast as she steamed; while the *Hermes* has no sail, and steams 20 knots, or 6 knots faster than did the older vessel. The *Inconstant* was entirely unprotected, and carried her guns on the broadside, with very limited arcs of training; whilst the *Hermes* has all-round fire, the fire ahead and astern is a very large percentage of that on the broadside, and her guns all train through large arcs (120° and above), and are well protected by enveloping shields, and the ship herself is protected by a steel deck 1½ to 3 in. thick, besides having coal protection. The *Inconstant's* main armament consists of ten 9-in. and six 7-in. M.L. guns; the *Hermes'*, of eleven 6-in. Q.F. guns, each firing probably ten rounds to one of the *Inconstant's* 9-in., and with a perforation of wrought iron of about one-third as much again. A glance at the pictures of the two ships (Figs. 48 and 58) shows a great difference in appearance. The line of the topsides of the *Inconstant* is unbroken from stem to stern; the *Hermes* has a forecastle forward, and amidships she has a large number of ventilators and funnels; and the contrast extends to all the principal features of the ships. The *Hermes* is built of steel, sheathed and coppered. She carries, in addition to her eleven 6-in. Q.F. guns, eight 12-pdrs. and six 3-pdrs., besides machine-guns and two submerged torpedo tubes. She has Belleville boilers, developing 10,000 H.P. and giving her a speed of 20 knots as long as her coal lasts.

Somewhat similar to the *Hermes* in external appearance, the four vessels of the *Arrogant* class (Fig. 59, Plate XIV.) possess certain features of special interest which distinguish them from all other second-class cruisers, in which class they are usually included. They are of 150 tons greater displacement than the *Hermes*, are 30 ft. shorter, but have 3 ft. 6 in. more beam and 6 in. more draught. They are built of steel and are unsheathed, have Belleville boilers, and engines giving 10,000 H.P. and a speed of 19 knots. They have an armament of four 6-in. Q.F. guns, three of which fire right ahead and one right astern; six 4·7-in. Q.F. guns, three on each broadside; eight 12-pdrs.; nine smaller guns; and two submerged torpedo tubes. All the guns are mounted on the upper deck in shields. The protective deck is of nickel steel, and varies from 1½ in. to 3 in. in thickness. The bow is protected by a belt of 2-in. nickel steel extending about 40 ft. back from the ram, the top of this belt being level with the main deck, and the bottom edge sloping downwards to strengthen the ram. The bow spaces are packed with a water-excluding material, and a cofferdam formed by two water-tight transverse bulkheads about 3 ft. apart, and extending from keel to main deck, separates the bow from the rest of the vessel. The *Arrogants* are fitted with tandem rudders, and the deadwood at the after end of the ship is cut away, the manœuvring power being greatly increased by these means. The strong bow fire, bow strengthening and protection, and great manœuvring power render these vessels specially adapted for use as rams.

The protected cruisers of greater displacement, or first-class cruisers, as they are called, may be divided into four well-marked classes: *Blake* and *Blenheim* class, *Edgar* class (Fig. 60, Plate XV.), *Powerful* and *Terrible* class (Fig. 61, Plate XV.), and the *Diadem* class (Fig. 62, Plate XV.). The *Blake* and *Blenheim*, begun in 1888, were amongst the earliest cruisers designed for the British navy by Sir William White in his capacity of Director of Naval Construction: they are of 9000 tons displacement, 375 ft. long, 65 ft. beam, and 27 ft. draught. They carry two 9·2-in. B.L. guns, one firing directly ahead and the other directly astern, protected by shields 6 in. thick; ten 6-in. Q.F. guns, of which four are on the main deck, protected by casemates of 6 in. compound armour, and six on the upper deck in shields; sixteen 3-pdrs.; two submerged and two above-water torpedo tubes. Their protection consists of a complete armour deck of steel 3 in. to 6 in. thick, with a dome or coaming over the tops of the cylinders 4 in. to 8 in. thick. Their machinery arrangements are somewhat unusual, consisting of four independent sets of vertical triple-expansion engines, two on each shaft, for which steam is provided from six double-ended cylindrical boilers. The aggregate power of their machinery is 20,000 H.P. under forced draught, giving them a speed of 21 knots; with open stokeholds their power is 13,000 H.P., which gives them a speed of 19¼ knots. They carry 1500 tons of coal. The *Edgar* class (Fig. 60), begun in 1889, are vessels of 7350 tons displacement, 360 ft. long, 60 ft. beam, and 23 ft. 9 in. mean draught. Their armaments consist of two 9·2-in. Q.F. guns and ten 6-in. Q.F., disposed and protected in the same way as the corresponding guns of the *Blake*, with twenty-four smaller and machine guns, two submerged and two above-water torpedo tubes. The protective deck has a maximum thickness of 5 in., and the cylinders are protected by a raised coaming on this deck, with sloping sides 6 in. thick. They have six double-ended cylindrical boilers and two sets of vertical triple-expansion engines, developing with forced draught 12,000 I.H.P. and giving a speed of 20 knots. They carry 850 tons of coal at normal draught, with storage for 1250 tons. Nine vessels of this class have been built, four of them being sheathed with wood and coppered, the remaining five, including the *Edgar*, being unsheathed. The *Powerful* (Fig. 61), with her sister the *Terrible*, was in 1902 the largest protected cruiser afloat. They were begun in 1894. They are of steel, sheathed with wood and coppered, are of 14,200 tons displacement, 500 ft. length, 71 ft. beam, and 27 ft. mean draught. They are armed with bow and stern 9·2-in. B.L. chasers, and twelve 6-in. Q.F. guns, of which eight are in 6-in. Harveyized casemates on the main deck and four in similar casemates on the upper deck. They have also seventeen 12-pdrs. Q.F. guns, twelve 4-pdrs., nine machine-guns, and four submerged torpedo tubes. The 9·2-in. guns are protected by a shallow ring of 6-in. Harveyized steel, surmounted by a 6-in. shield enveloping the gun and crew. The ship herself is protected by a complete deck at the water-line level of Harveyized steel plates 3 in. to 6 in. in thickness, and by a double line of coal bunkers above it. The machinery arrangements constitute the striking feature of these ships. They have no less than forty-eight Belleville boilers in eight boiler-rooms, with two sets of triple-expansion 4-cylinder engines, developing 25,000 H.P. with open stokeholds and giving the ships a speed of 22 knots. The large boiler power and the great size of these ships enable them to maintain continuously at sea a

First-class cruisers.

speed closely approaching their maximum. They carry as a normal supply 1500 tons of coal, and their bunkers will hold 3000 tons.

The *Diadem* class (Fig. 62) were in 1902 the latest first-class protected cruisers added to the British navy. There are eight vessels of this class, but in the four last-built vessels, of which the *Spartiate* was one, some changes were made. The first vessel of the *Diadem* class was begun in 1895, is of 11,000 tons displacement, 435 ft. length, 69 ft. beam, 25 ft. 3 in. mean draught, and is built of steel, sheathed and coppered. Her principal armament consists entirely of 6-in. Q.F. guns, of which there are sixteen, twelve being protected by 5-in. casemates of Harveyized steel, and the others disposed, two on the forecastle as bow chasers, and two on the quarter deck as stern chasers, all in separate shields. She also carries thirteen 12-pdrs., eleven smaller guns, including machine-guns, and two submerged torpedo tubes. The protection consists of a steel deck, whose slopes are 4 in. thick and horizontal portions 2½ in. thick, upon which is stowed the 1000 tons of coal which the vessel ordinarily carries, the full coal capacity being 2000 tons. She is provided with 30 water-tube boilers of the Belleville type, and her machinery develops 16,500 H.P., giving her a speed of 20·5 knots. All the ships of the class are similar to the *Diadem*, except that in the four *Spartiates* the casemates are 6 in. thick, and the machinery is of greater power, viz., 18,000 I.H.P., giving a speed of a quarter of a knot higher.

Third-class protected cruisers include vessels varying in displacement from 1500 to 3000 tons. The advances which enable modern second-class cruisers to compare so favourably with vessels of the same size built thirty years previously also enable vessels of even smaller displacement to be provided with the essential features of a cruiser to a considerable degree. With a reduction of displacement come reduction of initial cost and cost of upkeep, a smaller crew, a shorter time for building, and the many advantages attendant upon reduced size and draught of water. It has been found possible to embody in a ship of about 2000 tons displacement many of the most important requirements of a modern cruiser, and a large number of vessels of this class have been added to the fleet. Among these may be mentioned the *Barham* (Fig. 63, Plate XV.), a typical small cruiser, which was built in 1889 of steel, of 1830 tons displacement; she is 280 ft. long between perpendiculars, 35 ft. broad, and 12 ft. 8 in. draught of water. As originally completed, this vessel had cylindrical boilers and a H.P. of 4700, giving a speed of 19 knots. In 1898 she and her sister, the *Bellona*, were reboilered with water-tube boilers of the Thornycroft type, and with these a H.P. of 6000 is obtained, and the vessel reaches a speed of nearly 20 knots. The protection afforded is in the usual form of a protective deck, 1 in. thick on the flat, and sloping sharply downwards near the water-line, where the thickness is increased to 2 in.; and above this deck the coal stowage is arranged in subdivided bunkers. She carries an armament of six 4·7-in. Q.F. guns in shields on the upper deck, four 3-pdrs., two machine-guns, and two above-water torpedo tubes. She carries 140 tons of coal in her normal condition, and her bunkers will take 250 tons. She has a light fore-and-aft rig. The latest type of third-class cruiser added to the British navy in 1902 may be regarded as a development of the *Barham*. It is known as the *Pioneer* class, which might be taken to include the *Pelorus* class, the differences between them being small. Of the two classes eleven vessels have been built. The *Pioneer* is 305 ft. long, 36 ft. 9 in. broad, 13 ft. 6 in. mean draught, and 2200 tons displacement. She has water-tube boilers of the small tube type, and engines of 7000 H.P., giving her a speed of 20 knots. She carries 250 tons of coal at the above displacement, and has stowage for 550 tons. She has eight 4-in. Q.F. guns in shields on the upper deck, eight 3-pdrs., four machine-guns, and two above-water torpedo tubes. Her protection consists of a 2-in. steel deck, having sloping sides extending a few feet below the water-line, and upon which coal is stowed in the usual subdivided bunkers.

Third-class cruisers.

The *Impérieuse* and *Warspite*, built in 1881 from designs by Sir Nathaniel Barnaby, may be described as the first armoured cruisers built for the British navy. The *Impérieuse* is shown in Fig. 52, and the *Warspite* is a sister vessel. They are of 8000 tons displacement, 315 ft. long, and are protected by a partial belt amidships of 10-in. compound armour over a length of about 140 ft., with a protective deck above it 1½ in. thick, and transverse bulkheads at the ends of the belt 9 in. thick, the protective deck from these bulkheads to the ends of the ship being 3 in. thick. They have machinery of 10,000 H.P. and a speed of 16¾ knots. They rank in the Navy List of to-day as first-class armoured cruisers, and carry four 9·2-in. B.L. guns in separate barbettes—one forward, one aft, and one on each beam—besides ten 6-in. guns, twenty-six smaller and machine guns, and six torpedo tubes. They are sheathed and coppered, and are thus able to keep the sea for a long period without docking. The next vessels of the type were the *Orlando* class (Fig. 53), commenced in 1885. Seven of these were launched in 1886 and 1887. They are much smaller than the *Impérieuse*, being only 5600 tons displacement, 300 ft. long, 56 ft. beam, and 24 ft. 8 in. draught. They have a water-line belt of compound armour, 10 in. thick and nearly 200 ft. long, closed in at the ends by bulkheads 16 in. thick; extending over the top of this, and sloping down forward and aft to the ends of the ship, is a deck 2 in. to 3 in. thick. Their armament consists of two 9·2-in. B.L. guns—one forward and one aft—instead of the four carried in the *Impérieuse* and *Warspite*, but is in other respects the same as the armament of the latter ships. They have engines of 8500 H.P. and a speed of over 18 knots, are unsheathed, and carry 750 tons of coal, with bunker space for 950 tons.

Armoured cruisers.

As already stated, between 1885 and 1898 no armoured cruisers were added to the British fleet. The *Cressy* class (Fig. 54, Plate XII.), commenced in 1898, consists of six vessels of 12,000 tons displacement, 440 ft. length, 69 ft. 6 in. beam, and 26 ft. 3 in. mean draught. They are built of steel, sheathed and coppered, have a belt of Harveyized steel 11 ft. 6 in. wide, 230 ft. long, and 6 in. thick, with bulkheads 5 in. thick, and 2 in. protective plating on the sides from the forward bulkhead to the stem. They carry two 9·2-in. B.L. guns in barbettes and gun-houses 6 in. thick, mounted on the middle line forward and aft, twelve 6-in. Q.F. guns in 6-in. casemates, and twenty-five 12-pdr. and small guns, with two submerged torpedo tubes. Their H.P. is 21,000 with natural draught, steam being supplied by 30 Belleville boilers, and their speed is 21 knots. They carry 800 tons of coal at normal draught, with capacity for 1600 tons.

The four vessels of the *Drake* class (see Fig. 64, Plate XVI.), laid down in 1899, were in 1902 the largest armoured cruisers yet begun. They are of 14,100 tons displacement, are 500 ft. long, 71 ft. beam, and 26 ft. mean draught. They are unsheathed, are protected by a Krupp steel 6-in. belt extending from barbette to barbette, and from 5 ft. below water to the height of the main deck, completed at the after end by a 5-in. bulkhead, and carried forward to the bow by 2-in. plating extending right up to the upper deck. There are two protective decks, the lower being 3 in. to 2 in. in thickness, and the main deck, which is 1 in. thick. Their armament consists of two 9·2-in. B.L. guns in barbettes and gun-houses 6 in. thick on the middle line forward and aft, sixteen 6-in. Q.F. guns in 6-in. casemates, fourteen 12-pdrs., twelve smaller and machine guns, and two submerged torpedo tubes. Their speed was superior to anything in the British navy up to the time of their design, being 23 knots.[1] They have engines of 30,000 H.P., the boilers being of the Belleville type. They carry 1250 tons of coal, with bunker capacity for 2500 tons.

A consideration of the above features will illustrate the difficulties of the classification of modern ships. The *Drake* is called an armoured cruiser, but she is superior to the battleships *Renown*, *Barfleur*, and *Canopus* in armour protection and in her secondary quick-firing armament, as well as in speed and coal endurance, and is somewhat inferior to them only in the number, weight, and protection of primary armament. If 10-in. guns were given to this vessel in lieu of her 9·2-in., she would probably be called a first-class battleship, and would be a 23-knot battleship at that. Each successive increase of size has given the battleship more speed and the armoured cruiser heavier guns and armour, thus tending to merge the two types in one.

The *Monmouth* class are smaller and more lightly armed and armoured vessels than their predecessors, but not inferior in speed. They are of 9800 tons displacement, length 440 ft., beam 66 ft., mean draught 24 ft. 6 in. They are armoured with a belt of 6 in. of Krupp steel over the main part of the length, diminishing in thickness towards the extremities; they carry fourteen 6-in. Q.F. guns, of which ten are in 4-in. casemates, and the others mounted in pairs in turrets and gun-houses 4 in. thick, forward and aft; they also carry ten 12-pdrs., eleven small and machine guns, and two submerged torpedo tubes. Their horse-power is 22,000, giving them a speed of 23 knots. In six vessels of this class, begun in 1901, the pairs of 6-in guns are replaced by 7·5-in. guns, and the thickness of the belt is increased to 6 inches.

With regard to cruisers of other navies than the British, it may be said that the vessels constructed at Elswick have by their success exercised considerable influence in the development of such cruisers, as well as of those of the British navy. The *Esmeralda* of 1883 (Fig. 51, Plate XI.), built for the Chilian Government, but bought by Japan in 1895, was of 2950 tons displacement, had 6000 H.P. and 18·3 knots speed, was protected by a complete 1-in. steel deck, and carried the very heavy armament of two 10-in. B.L. guns, six 6-in. Q.F., two 6-pdrs., seven smaller guns, and three torpedo tubes. The *Piemonte* (Fig. 65, Plate XVI.), built for the Italian navy in 1888, had a displacement of only 2640 tons, but was of 13,000 H.P. and had a speed of nearly 22½ knots. She was protected by a steel deck of 3 in. maximum thickness, and carried six 6-in. Q.F., six 4·7-in. Q.F., ten 6-pdrs.,

[1] The *Drake* herself in September 1902 obtained on trial a speed over 24 knots.

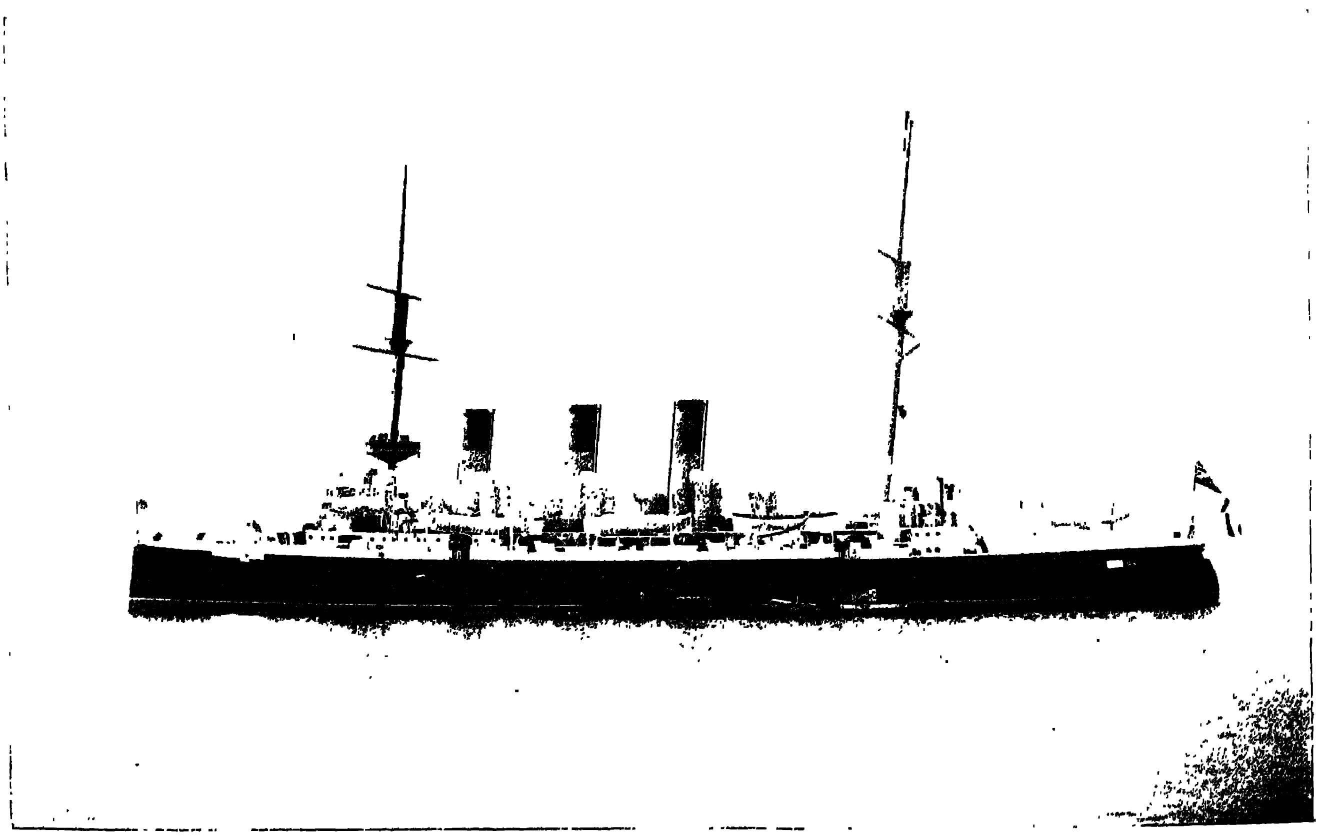

FIG. 59.—H.M.S. *Arrogant.*

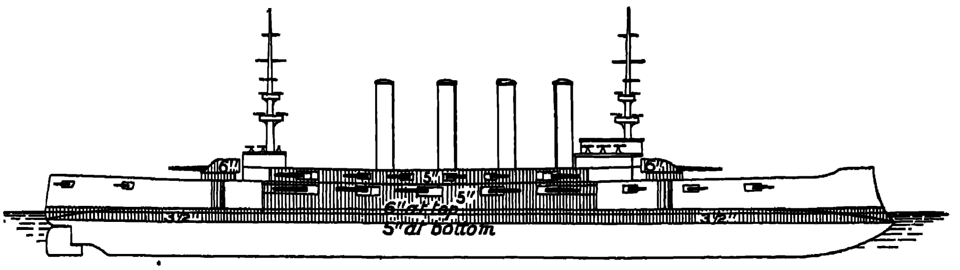
eleven smaller guns, and three torpedo tubes, an armament which, as pointed out by Lord Armstrong, was capable of discharging in a given time twice the weight of shot and shell that could be fired by the largest war vessel then afloat. The *Buenos Aires*, built in 1895 for the Argentine Republic, is a later example of Elswick design. She is 396 ft. in length and of 4800 tons displacement, her machinery developing 13,300 horse-power with open stokeholds, and giving her a speed of 23·2 knots. She is protected by a complete deck 1½ in. to 3 in. thick, and carries a powerful armament of quick-firing guns, consisting of two 8-in., four 6-in., six 4·7-in., twenty-two smaller guns, and five torpedo tubes. Her normal coal supply is 350 tons, and she can stow 1000 tons in her bunkers. Rather smaller than the *Buenos Aires*, but of still later build (1901), is the Chilian cruiser *Chacabuco* (Fig. 66, Plate XVI.). She is a characteristic Elswick cruiser in design and general appearance, being heavily armed, fast, and of moderate displacement. Her dimensions are: displacement 4500 tons, length 360 ft., breadth 46 ft., and draught 18 ft. She carries an armament of two 8-in. Q.F. guns, mounted on the middle line forward and aft, and protected by well-armoured gun-houses, ten 4·7-in. Q.F. guns in shields on the broadsides, and nineteen smaller guns, including machine-guns. She is protected by a strong armoured deck 1¾ in. thick on the flat to 4½ in. on the slopes, and by the 1000 tons of coal which forms her normal supply. Her engines develop nearly 16,000 H.P., and her speed is 23 knots.

In the matter of armoured cruisers also Elswick has taken a leading place, the policy which has been so successful in the case of protected cruisers being followed with these also, with the difference that in the armoured cruisers the main protection takes the form of side armour instead of, or rather in combination with, protective deck-plating. From what has been said previously as to the functions of armoured cruisers, it might be expected that the displacements of these ships built at Elswick would be greater than the protected cruisers, but with these also the endeavour was to keep displacement at the minimum. Examples of Elswick designs are found in the *Esmeralda* (second), of 7000 tons, begun in 1895 for Chile; the *O'Higgins*, of 8500 tons, begun in 1896 for the same state; the *Asama* and *Tokiwa*, of 9700 tons, begun in 1897 for Japan; and the *Idzumo* and *Iwate*, begun 1899, also for Japan. The *Idzumo* (Fig. 67, Plate XVII.) is 9750 tons displacement—or about the same as the English *Monmouths*—400 ft. long, 68 ft. 6 in. beam, 24 ft. 3 in. draught. She has 16,000 H.P. and a speed of 22 knots; is protected by a complete belt of Krupp steel 7 in. thick, tapering to 3½ in. at the ends, a 2½-in. steel deck with a citadel above it 5 in. thick, and carries an armament of four 8-in. Q.F., fourteen 6-in. Q.F., twelve 12-pdrs., seven smaller, and four torpedo tubes. The 8-in. guns are in pairs in 6-in. barbettes and hoods, while the 6-in. guns are ten in 6-in. casemates and four in shields. She carries, with bunkers full, 1300 tons of coal. Particulars of some further examples of Elswick cruisers will be found in Table VII.

United States.—In the United States navy the proportion of "protected" cruisers is smaller than in the British navy, as the "armoured" type established itself at an earlier date. The *Philadelphia*, begun in 1888, may be taken as an example of the U.S. protected cruiser. She is 4345 tons in displacement and 327 ft. long, has twin screws and a horse-power of 8800, giving her a speed of 19·6 knots. She is protected by a steel deck 2½ in. to 4 in. thick, and carries twelve 6-in. B.L. guns (later converted to Q.F.), seventeen smaller guns, and five torpedo tubes. She has bunker capacity for 1175 tons of coal. The *Brooklyn* (Fig. 55, Plate XII.), begun in 1893, is of the "armoured" type. She is of 9215 tons displacement and 400 ft. long, has twin screws and develops 16,000 horse-power with forced draught, giving a speed of 21 knots. She is protected by a steel belt for two-thirds of her length 8 ft. broad and 8 in. to 3 in. thick, and a complete steel deck 6 in. to 3 in. thick. She carries eight 8-in. B.L. guns in pairs in



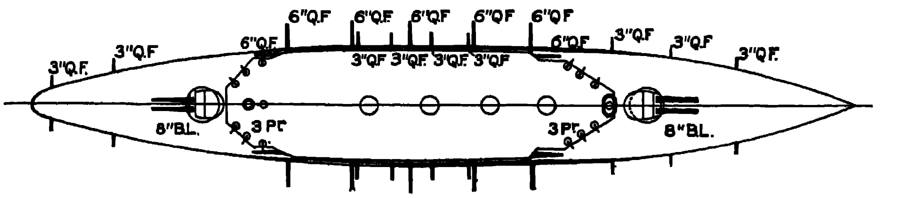


FIG. 68.—Plan of *California*.

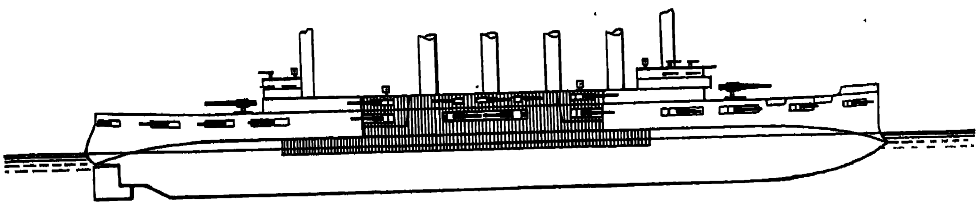
15-in. barbettes—disposed one forward, one aft, and one on each beam—twelve 5-in. Q.F. guns in 4-in. shields, twenty smaller guns, and five torpedo tubes. Her normal coal stowage is 900 tons, and she can stow 1650 tons in her coal spaces.

In 1902 there were building, or projected, six armoured cruisers of the *California* class (Fig. 68), of 13,700 tons, and three of the *St Louis* class (Fig. 69), of 9700 tons. The former are vessels 502 ft. in length 70 ft. beam, and 26 ft. 6 in. draught, have machinery developing 23,000 indicated horse-power, and a speed of 22 knots. The latter are 424 ft. in length, 66 ft. beam, and



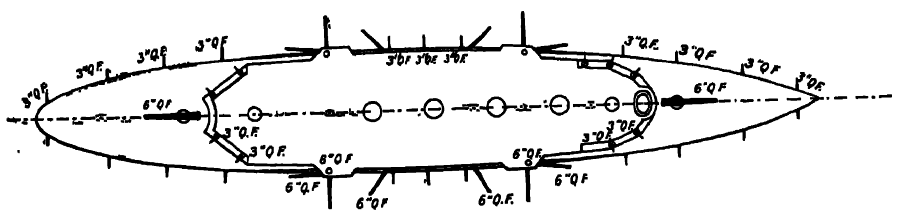


FIG. 69.—Plan of *St Louis*.

23 ft. 6 in. draught, with engines of 21,000 indicated horse-power, and the same estimated speed, namely, 22 knots. Both classes have fourteen 6-in. Q.F. guns, but the larger vessels have in addition four 8-in. guns in two 6½-in. turrets, besides a heavier battery of smaller Q.F. guns. The *California* class are completely belted with armour having a thickness of 6 in. over half the length amidships and 3½ in. to the ends, and a battery of 5-in. armour enclosing the 6-in. Q.F. guns, and extending to the upper deck. The *St Louis* class have only a water-line belt for about one-half the vessel's length, with a similar battery above it, the whole of the armour being 4 in. thick of Krupp quality. The *California*

class comes between the English *Cressy* and *Drake* classes. The *St Louis* class is practically the English *Monmouth*, with about a knot less speed, bow-plating omitted, and a 4-in. battery added.

France.—A good example of the modern French cruiser is afforded by the *Jeanne d'Arc*, launched in 1899 at Toulon. She is about 11,300 tons displacement, 477 ft. in length, 63 ft. 8 in. beam, and 24 ft. 8 in. mean draught, has engines of 28,500 indicated horse-power, and a speed of 23 knots. In accordance with the usual practice of the French navy, she has a complete water-line armour belt of Harveyized steel, having a maximum thickness of 6 in., and the bow is also protected as far aft as the bow guns with $1\frac{1}{2}$ in. steel to the upper deck. Her armament consists of two 7·5-in. guns, fourteen 5·5-in. Q.F., twenty-two smaller guns, and two submerged torpedo tubes. Of more recent date than the *Jeanne d'Arc*, but smaller in size, is the *Montcalm* (Fig. 70, Plate XVII.), an armoured cruiser launched in March 1902, of 9500 tons displacement, 453 ft. length, 63 ft. 8 in. beam, and 24 ft. 6 in. draught. She carries an armament of two 7.6-in. guns in separate turrets of Harveyized steel 6 in. thick forward and aft, eight 6·4-in. Q.F. guns in casemates on the broadsides, four 3·9-in. Q.F. guns in shields on the broadsides, twenty-two smaller guns, and two submerged torpedo tubes. She is protected by a water-line belt $6\frac{1}{2}$ ft. deep which extends from the bow to within 30 ft. of the stern, where it is terminated by a transverse bulkhead 4 in. thick; amidship this belt is 6 in. thick at its upper edge, diminishing to 2 in. at its lower edge, where it meets the 2-in. protective deck, but the maximum thickness tapers to 3 in. at the forward and after ends. Above this main belt is a thinner one extending over the same length, but only $3\frac{3}{4}$ in. maximum thickness and of about 4 ft. depth. The *Montcalm* has 20 water-tube boilers of the Normand-Sigaudy type, and engines of 19,600 H.P., giving her a speed of 21 knots. She carries 1000 tons of coal and some oil fuel. Her engine-rooms are placed between the two sets of boiler-rooms, instead of abaft them, as is usual, her peculiar appearance, with two pairs of funnels widely separated, being thus accounted for. There were also in hand in France in 1902 three armoured cruisers of the *Gambetta* class, of about 12,400 tons displacement, length 480 ft., beam 70 ft. 3 in., draught 26 ft. 3 in., with an indicated horse-power of 27,500 and an estimated speed of 22 knots. These ships approach in size and type to the *Drake* class in H.M. navy, particulars of which are given on page 566. They compare very favourably so far as water-line protection is concerned, but there is considerable difference in the armament, the *Drake* having two 9·2-in. against four 7·6-in. in the *Gambetta* for main armament, and sixteen 6-in. Q.F. against sixteen 6·4-in. Q.F. for secondary armament.

Russia.—In 1902 the latest armoured cruiser added to the Russian navy was the *Bayan*, launched at La Seyne, June 1900. She has a displacement of 7800 tons, and is 445 ft. in length, 56 ft. 9 in. beam, and 22 ft. mean draught. Her armament consists of two 8-in., eight 6-in. Q.F., twenty 2·9-in. and seven 1·8-in. guns, and six torpedo tubes. Her armour consists of a water-line belt, having a maximum thickness of 8 in. Above the belt, and for a length of 335 ft. from forward, she is protected with 3-in. steel, which encloses the forward 8-in., six 6-in. Q.F., and the eight 2·9-in. guns, the two aft 6-in. Q.F. and aft 8-in. gun being separately protected. She has 26 Belleville boilers, engines of 16,500 I.H.P., and a speed of 21 knots, which it is expected will be maintained on a 24 hours' trial. The *Bogatyr* (Fig. 71, Plate XVII.), of 6570 tons, was launched at Stettin for the Russian Government in January 1901; she is a somewhat similar vessel to the *Variag*, of 6500 tons, built by Messrs Cramp, Philadelphia, in 1899. These two vessels are protected cruisers; the latter obtained a speed of 24·6 knots on the measured mile, and maintained a continuous speed of over $23\frac{1}{2}$ knots for $7\frac{1}{2}$ hours before leaving the builders' hands. Two more vessels of the *Bogatyr* type were building, and another was projected. Three other ships of approximately the same displacement, *Pallada* class, have also been added to the Russian navy, but these have a speed of only 20 knots. The *Gromoboi*, armoured cruiser of 12,336 tons, length 473 ft., beam $68\frac{1}{2}$ ft., and draught 26 ft., was launched in 1899. She has an indicated horse-power of 14,500, a speed of 20 knots, and carries an armament of four 8-in. Q.F., sixteen 6-in., twenty-four 3-in., and eight small Q.F. guns, &c., with four torpedo tubes. She has a partial armour belt of 6 in. Harveyized steel, and the main gun positions are also protected by 6-in. armour. A special type of vessel recently evolved, and now building for the Russian Government, is the light cruiser or enlarged torpedo-boat destroyer *Novik*, of which the following particulars have been published. Principal dimensions: displacement 3000 tons, length 361 ft., beam 40 ft. 1 in., draught 19 ft., armament six 4·7-in. Q.F. guns, nine smaller guns, and six above-water torpedo tubes. She has a 2-in. protective deck, 16 Belleville boilers, engines of 17,000 indicated horse-power, and a speed of 25 knots. Particulars of the armoured cruisers *Rurik* and *Rossia*, which excited so much attention at the time they were built, are given in Table VII., and the latter ship is shown by Fig. 72 (Plate XVII.).

Table VII. gives in chronological order particulars of the leading types of cruisers—armoured, deck-protected, and unprotected—of various nations, from the *Inconstant* of 5780 tons to the *Drake*, 14,100 tons, and *Monmouth*, 9800 tons, and shows the progress made in this type of warship during the period 1866–1900.

Gunboats and Torpedo Craft.

Gunboats include numerous small vessels which, even in times of general peace amongst the great maritime nations, have important duties allotted to them. For the patrolling of rivers and islands, protection of fisheries, &c., a battleship or a cruiser, from its size, would be unsuitable, and for the performance of these and other duties special vessels have been built. These types, and those included in the torpedo-craft division, may for our purposes be conveniently grouped under three headings, as follows:—

I. Sloops.
II. Gun-vessels and Gunboats.
III. Torpedo-Boats, Torpedo Gunboats, and Torpedo-Boat Destroyers.

Sloops. The *Wild Swan* class (Fig. 73, Plate XVIII.), the first of which was launched in 1876 for the British navy, represents one of the earliest of the sloop type. She was a single-screw composite-built vessel of 1130 tons displacement and 170 ft. length, with a speed under steam of $10\frac{1}{2}$ knots and an armament of two 6-in., six 5-in. B.L. guns, and four smaller guns. This proved a very useful class of ship, and in all sixteen of them were built. The *Beagle* class (Fig. 74, Plate XVIII.), commenced in 1889, represented an advance on the *Wild Swan*. They were built of steel, sheathed with wood and coppered, and had twin screws. Their displacement was 1170 tons, and they were 195 ft. long, steamed at 13 knots, and carried eight 5-in. B.L. guns and eight machine-guns. They were followed, at an interval of five years, by the *Torch* and *Alert*, the immediate forerunners of the *Condor* class, which were of 960 tons displacement, 180 ft. long, steamed at $13\frac{1}{4}$ knots, and carried an armament of six 4-in. Q.F. guns, four 3-pdrs., and two machine-guns. They were single-screw vessels, built of steel, sheathed and coppered. The *Condor* class, which comprises six vessels built between 1898 and 1901, are very slightly modified *Torches*, having 20 tons more displacement and 6 in. more beam, with the same length, speed, and armament. They are able, however, to maintain a higher continuous speed, being fitted with water-tube boilers. In 1902 there were under construction four sloops of the *Fantôme* class, which are larger vessels than the *Condors*, being 1075 tons displacement and 185 ft. long. They are twin-screw vessels, built of steel, sheathed and coppered. They have water-tube boilers, giving 1400 H.P., and will attain a speed of $13\frac{1}{4}$ knots. Their armament is similar to that of the *Condor*. All the foregoing vessels are fitted as sailing vessels as well as steam. The *Beagle* is schooner-rigged, the others all barque-rigged. In their general arrangements the differences between the above-described classes of vessels are not great, and the illustrations given of the *Wild Swan* and *Beagle* will serve to give a fair idea of the general appearance of all of them.

Gunboats. Of the gun-vessel or gunboat type, one of the earliest built for the British navy is represented by the *Staunch*, a twin-screw vessel designed by Mr G. W. Rendel, and built at Elswick in 1867. The guiding principle in the design of this vessel was that she should simply be a floating gun-carriage, propelled by steam and provided with plenty of manœuvring power. The 9-in. 12-ton gun which constituted her armament was arranged to sink into and be raised from a well by means of hydraulic power. She was only 180 tons in displacement and 75 ft. long, and had a speed of $6\frac{1}{2}$ knots. The *Medina* class (Fig. 75, Plate XVIII.), consisting of twelve gunboats built about 1876, were twin-screw vessels of 363 tons displacement and 110 ft. length, and had a speed of $8\frac{1}{4}$ knots. Their armament was light, consisting only of three 64-pdrs. and three machine-guns. They were fitted with bow rudders in addition to those at the stern, in order to increase their manœuvring power. In the *Cockchafer* class (1881) and the *Thrush* class (1889) successive increases of size and speed were made. The former, of which four were built, are composite-built single-screw ships of 465 tons displacement and 125 ft. length, with a fore-and-aft rig and a speed under steam of $9\frac{1}{2}$ knots. The latter, of which there are nine, are schooner-rigged composite vessels of 805 tons displacement and 165 ft. length, with a single screw and a speed of $13\frac{1}{2}$ knots. The armament of the *Cockchafers* consisted of two 64-pdr. R.M.L. guns, two 20-pdr. R.B.L. guns, and two machine-guns; that of the *Thrush* (Fig. 76, Plate XVIII.) consisted of six 4-in. B.L. guns and four smaller guns. The *Bramble*, launched in 1898, is a

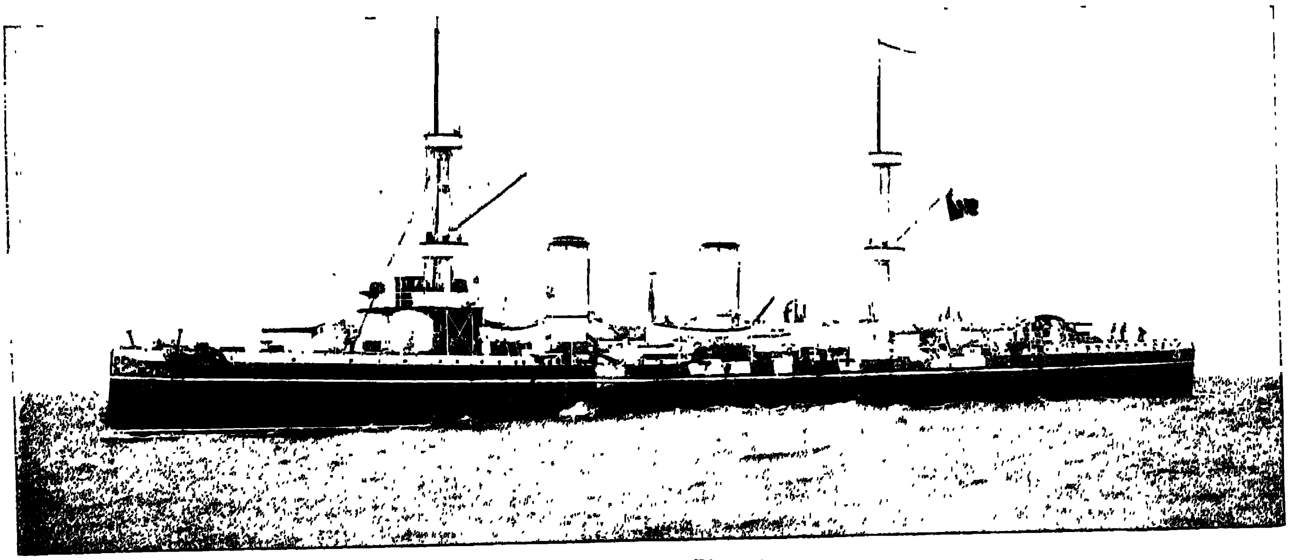

FIG. 65.—Italian *Piemonte*.

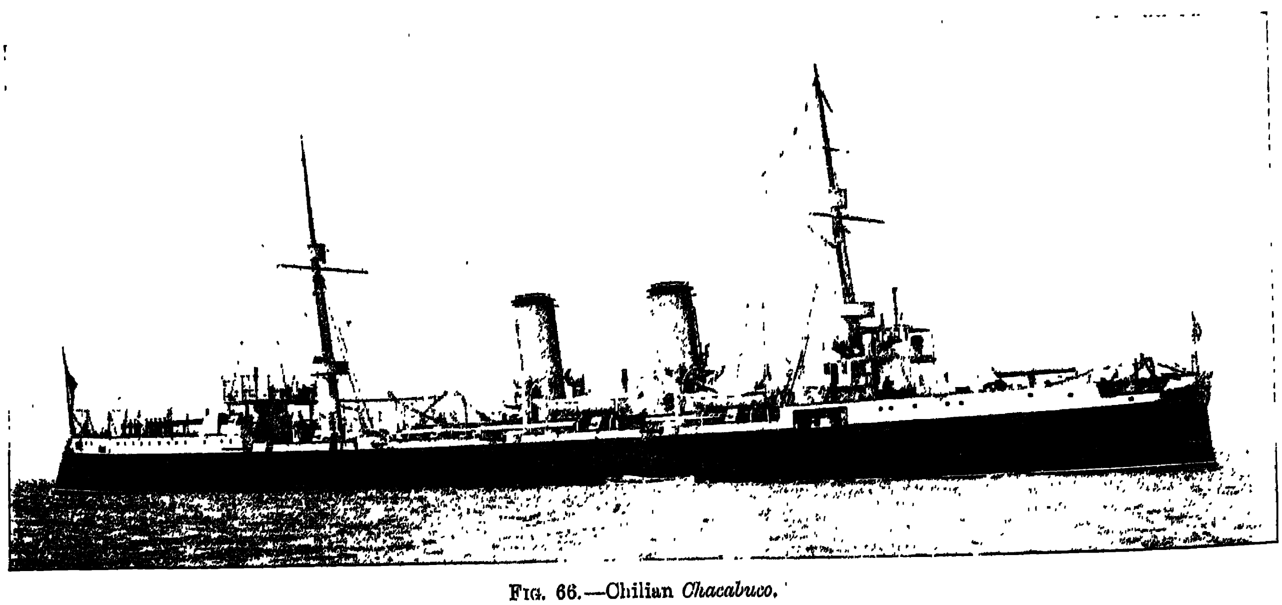

FIG. 66.—Chilian *Chacabuco*.

representative of the most recent type of first-class gunboat. Her displacement is 700 tons, or 105 less than the *Thrush*. She is 180 ft. long and has a speed of 13½ knots, is built of steel, sheathed and coppered, and carries two 4-in. Q.F. guns, 4 12-pdrs., and ten machine-guns. She has water-tube boilers, twin screws, and a light fore-and-aft rig. Four of these vessels have been built.

A number of gun-vessels have been designed for special services, among which may be mentioned the *Mosquito* and *Herald* (Fig. 77, Plate XVIII.), two stern-wheel steamers for the Zambezi built by Messrs Yarrow in 1890. They are of 80 tons displacement and 77 ft. long, having a speed of 10½ knots and carrying an armament of four 3-pdrs. and eight machine-guns. They are built in sections, each of which forms a separate pontoon, so that the whole vessel can be readily taken to pieces for transport and easily put together in the water. Built for somewhat similar service but of different design are the six shallow-draught river gunboats of the *Sandpiper* class. They are steel twin-screw boats, built in 1897, also by Messrs Yarrow. They are 88 tons in displacement, 100 ft. long, and 20 ft. broad, and carry an armament of two 6-pdrs. and four machine-guns. Their speed is 9 knots, and they draw only 2 ft. of water, their screws working in arched tunnels, the summits of which are above the water-level outside. These arches always remain full of water, and serve the double purpose of enabling sufficiently large screws to be fitted for the economical propulsion of the vessel without increasing the draught, and of protecting them from damage. Two of these boats have been in service on the Niger, two in South Africa, and two on the Chinese station. In appearance they are somewhat similar to the *Mosquito*. The *Woodcock* and *Woodlark* are larger vessels of the same type, designed for service on the rapid and shallow rivers of China. They were built by Messrs Thornycroft in 1897, are 120 tons in displacement, 145 ft. long, 23 ft. beam, and 2 ft. draught of water. They have twin-screws, also carried in arched tunnels, and their speed is 15 knots. They carry the same armament as the *Sandpiper* class. In 1902 the two latest examples of this type of vessel built for the British navy, the *Teal* and *Moorhen*, designed for service in China, were also constructed in sections, but are considerably larger than either the *Mosquito* or the *Woodcock*, being about 180 tons displacement. They are twin-screw vessels, the propellers being in tunnels, as in the *Woodcock*, and their speed is over 13 knots. Their furnaces will burn wood. They carry two 6-pdrs. and four machine-guns.

Figs. 78 and 79 (Plate XVIII.) show a light-draught gunboat of the *Sultan* class, of which several have been built for service on the Nile. She has a displacement of 140 tons, a length of 143 ft., a beam of 24 ft. 6 in., a draught of only 2 ft., and a speed of 12 knots. Her armament consists of one 12-pdr., one howitzer, and four Maxims, and she is protected by a ⅛-in. bullet-proof breastwork.

Other Countries.—The gunboats of other navies are generally similar to those described above. Fig. 80 (Plate XIX.), which represents the *Iota*, is typical of eleven twin-screw gunboats built at Elswick for the Chinese Government between the years 1876 and 1881, and named after letters of the Greek alphabet, but afterwards given Chinese names. They were of 440 tons displacement and 126 ft. long, and had a speed of 10¼ knots; they carried one 11-in. 35-ton gun forward and two 12-pdrs. aft. The 35-ton gun could only be trained by moving the boat, but it could be loaded and elevated by hydraulic power. The *Palumah* and *Gagundah* (Fig. 81, Plate XIX.) were built at Elswick in 1884 for the Queensland Government. They have a displacement of 360 tons and are 115 ft. in length, were schooner-rigged, but had twin screws and a speed under steam of 10 knots. They carried one 8-in. B.L. gun forward, which was mounted behind a breastwork and had a considerable arc of training; one 6-in. gun, which was mounted aft; and three machine-guns. The *Protector* was a more important craft. Built for the Government of South Australia in 1884, she was 920 tons in displacement and 180 ft. long, had twin screws and a speed of 14 knots under steam. She carried one 8-in. B.L. gun forward, mounted as in the *Palumah*, five 6-in. 4-ton guns, and five Gatlings. The Brazilian twin-screw gunboat *Tiradentes*, built in 1892, of steel sheathed with teak and coppered, was only 165 ft. long and 800 tons displacement, but attained a speed of 14·5 knots. She had an armament of four 4·7-in. guns, three 6-pdrs., and four machine-guns, and carried a considerable spread of canvas.

In torpedo gunboats and torpedo craft generally, possibly the last thirty years of the 19th century showed more development and greater diversity than in any other type of war vessel now existing. The first small high-speed boat we have any record of is the *Miranda*, built by Messrs Thornycroft early in 1872. She was 45 ft. in length, 6½ ft. beam, and 2½ ft. draught, and attained a speed of 16·4 knots with a single screw, the engine running at 355 revolutions per minute and indicating 58 H.P. The results obtained with her attracted much attention, and the following year Messrs Thornycroft launched for the Norwegian Government a somewhat larger boat, armed with a spar torpedo, which attained a speed of 15 knots. The first torpedo-boat for the British navy was built by Messrs Thornycroft four years later; she was called the *Lightning*, was 75 ft. in length and 34 tons displacement, had engines giving nearly 500 H.P., and obtained a speed of 19 knots. She was armed with a single torpedo tube. The boats which followed varied somewhat as regards size and speed, but on the whole pursued the usual course of growing larger and more powerful with each new design. By 1885 the length had gone up to 150 feet, the displacement to 125 tons, and the speed to 20 knots. This last was not the highest that had been obtained, some of the earlier and smaller boats having reached 21½ knots; but the boats of 1885 carried a heavier armament, consisting of six 3-pdrs. and three torpedo tubes, and were more serviceable and seaworthy craft.

Torpedo craft.

The torpedo-boat thus established was primarily a weapon of offence, the only two elements of a protective nature in its design being those of small size and high speed; but even these were also necessary for purposes of offence. The deadly nature of their attack, and the difficulty of meeting it in the ship attacked, led to the construction of special vessels intended, among other duties, to

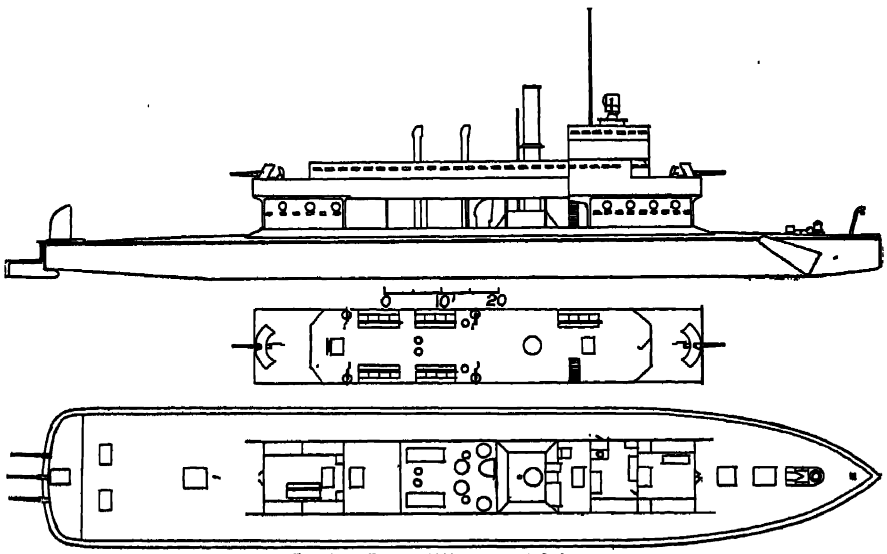

FIG. 78.—Plan of Nile gunboat *Sultan*.

meet and destroy them. The French *Bombe* (1885) was one of the earliest of these; and the *Rattlesnake* and three sister vessels, the first of the English torpedo gunboats, came closely after her. The *Rattlesnake* (Fig. 82, Plate XIX.) was launched in 1886, was of 525 tons displacement, and had a speed of 19¼ knots. She carried a more powerful armament than the torpedo-boats, namely, one 4-in. gun, six 3-pdrs., and 4 torpedo tubes. She was followed in 1888 by the *Sharpshooter*, with ten sister vessels, which were still larger and more heavily armed. They were 230 ft. long and 735 tons displacement, had engines developing 3500 H.P., giving a speed of 19 knots, and carried two 4·7-in. Q.F. guns, four 3 pdrs., and two torpedo tubes. Fig. 83 (Plate XIX.) shows one of this class, the *Karrakatta*, built at Elswick for service in Australian waters. The *Niger* (Fig. 84, Plate XX.) class of 1892, which included eleven vessels, were repeats of the *Sharpshooters*, except that they carried an additional torpedo tube and three machine-guns, with certain hull additions and more durable machinery, the displacement being increased by these causes to 810 tons, and the speed being reduced by a quarter of a knot. In 1893 a fourth series of this class of vessel was begun, known as the *Dryad* class, and considerably larger than the *Nigers*, being 250 ft. long and of 1070 tons displacement. They are of 3500 I.H.P., have a speed of 18¼ knots, and carry an armament of two 4·7-in. Q.F. guns, four 6-pdrs., and three torpedo tubes. Five vessels of this class were built, the difference between their general appearance and that of the preceding classes being illustrated by Fig. 85 (Plate XX.), which shows the *Hazard*, a vessel of this class, now employed on special service in connexion with the reception and trials of British submarines. In these thirty-one vessels of the torpedo

gunboat class the elements of strength and seaworthiness are developed at the expense of speed, and they combine in themselves some of the functions of the torpedo-boat with many of the most important features of the small cruiser. The successive increases of displacement are very largely due to additions to the hull, giving greater habitability and trustworthiness for continuous work at sea. It will be noticed that the speed shows a continuous falling off; but the *Sharpshooter* class and subsequent vessels are being refitted with water-tube boilers in lieu of the locomotive boilers originally fitted, and some of them are in addition being re-engined, with the result that a speed of 21 knots is now obtained; this, in the ordinary weather met with at sea, would probably enable them to overtake craft of lighter types possessed of considerably greater smooth-water speeds.

Torpedo-Boat Destroyers were primarily, as their name implies, intended to meet and destroy torpedo-boats, their larger size, greater coal capacity, heavier armament, and higher speed enabling them to overtake such boats before they could complete their attack; but it soon became evident that these additional powers also enabled the destroyer to perform the duties of the torpedo-boat more efficiently than the boat herself, and with the advent of the destroyer the production of the smaller boat declined. At the present time it is doubtful whether the offensive power of the destroyer, regarded as a torpedo-boat for use against an enemy's fleet or ports, is not of more importance than her protective power to the fleet or port to which she is attached.

The pioneers of this type of vessel were the *Daring*, *Decoy*, *Havock*, and *Hornet*, the construction of which was entered upon in July 1892, the two first-named at Messrs Thornycrofts and the other two at Messrs Yarrows. They were thus contemporary with the *Dryads*, the last of the torpedo gunboats. The *Daring* and *Decoy* were 185 ft. long, 19 ft. broad, 6½ ft. mean draught, and 265 tons displacement, had 4200 H.P., and reached a speed of 27 knots. They were armed with one 12-pdr., three 6-pdr. Q.F. guns, and three torpedo tubes. The *Havock* and *Hornet* were somewhat smaller, being 5 ft. shorter, 6 in. less beam, and 25 tons less displacement, and they carried the same armament. The *Havock* developed 3000 H.P. and had a speed of 26 knots; the *Hornet*, 3800 H.P. and 27 knots. The success of these four vessels was followed with great interest, and in the following year (1893) six others were begun, three of 26 knots speed and three of 27 knots; but the size went up to a displacement of 250 to 290 tons, and a length of 190 to 200 ft., while the power ranged between 3000 and 4400 H.P. A much greater number of destroyers (32 in all), nearly the whole of which were of 27 knots speed, were laid down in 1894. The sizes of these boats varied considerably, the displacement ranging from 265 to 295 tons and the length from 190 to 208 ft., while the power varied between 3600 and 4500 H.P. The succeeding year (1895) saw a great advance in size, power, and speed, thirteen destroyers being laid down, for each of which the contract speed was 30 knots. The displacement varied from 300 to 360 tons, the lengths from 208 to 215 ft., and the power from 5700 to 6200 H.P. Since 1895 these 30-knot destroyers have been built in considerable numbers; and although in 1896 an attempt was made to realise

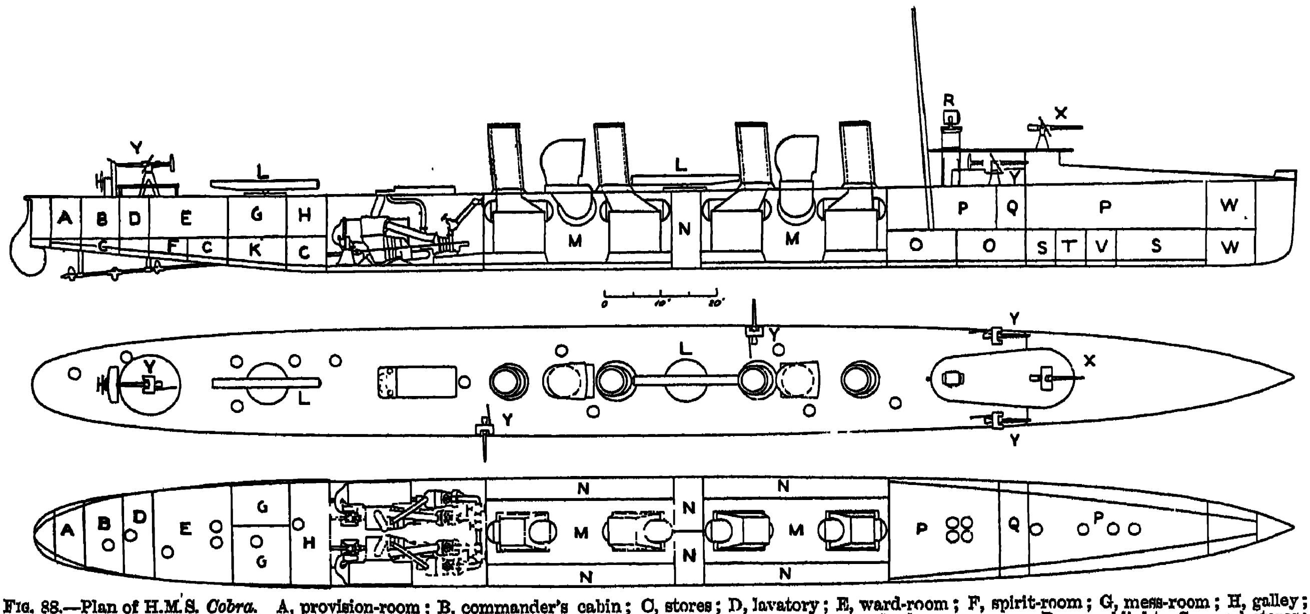

FIG. 88.—Plan of H.M.S. *Cobra*. A, provision-room; B, commander's cabin; C, stores; D, lavatory; E, ward-room; F, spirit-room; G, mess-room; H, galley; K, torpedo heads; LL, torpedo tubes; MM, boiler-rooms; N, coal; O, magazines; P, crew's space; Q, dynamo-rooms; R, searchlight; S, naval stores; T, provision-room; V, slop-room; W, chain locker; X, 12-pdr. Q.F. gun; Y, 6-pdr. guns.

even greater speeds than this, it was found that the power and cost necessary for the addition of a few knots were disproportionate to the value of the results obtained, and the attempt has not been followed by any general increase of speed above 30 to 31 knots. The general appearance of a typical modern destroyer is shown by Fig. 86 (Plate XX.), which represents the *Albatross* at full speed. She was built in 1896 at Messrs Thornycrofts' works, is 225 ft. long, 21¼ ft. broad, 7½ ft. mean draught, and about 380 tons displacement. Her I.H.P. is 7500, and she has a speed of 31¼ knots, which makes her the fastest destroyer at present in the British navy. She carries one 12-pdr., five 6-pdrs., and two torpedo tubes.

Particulars of some other destroyers will be found in Table VIII., which also gives particulars of many other British and foreign torpedo vessels of various types which have been built between the time of the *Miranda* and that of the *Cobra*, some of which are not described in the text.

Turbine-Steamers.—While, however, the attempt to obtain speeds greater than 31 knots from torpedo-boat destroyers by the expedient of putting into them the lightest and most powerful boilers and reciprocating engines has not been completely successful, considerably greater speeds have been actually obtained by the adoption of turbine machinery. Experience with the marine steam turbines, the invention of the Hon. C. A. Parsons, dates only from the time of the *Turbinia* (Fig. 87, Plate XXI.), which made her successful trials in 1898 after much investigation and preliminary work on the part of the inventor. This boat had a length of 100 ft., a breadth of 9 ft., a draught amidships of 3 ft., and a displacement of 44½ tons, and she attained a speed of 34½ knots with 2200 revolutions per minute and an estimated H.P. of 2300. The turbine machinery consisted of three separate turbines directly coupled to three screw shafts and working in series, one turbine being high pressure, one intermediate, and one low pressure. Each screw shaft carried three propellers, the total number of propellers thus being nine; the weight of main engines was approximately 3 tons 13 cwt., and the total weight of machinery and boiler, screws and shafting, tanks, &c., 22 tons. The boilers are of the water-tube type, with a working pressure of 225 ℔ per square inch.

The *Turbinia* was followed by the *Cobra* (Fig. 88) and *Viper* torpedo-boat destroyers, which had a length of 210 ft., a breadth of 21 ft., and a mean draught of 6 ft. 9 in. The machinery of these boats consisted of two sets, one on each side of the ship; each set had two expansions and drove two shafts (making four shafts in all), and the outer shaft on each side was driven by a high-pressure turbine, from which the steam passed to a low-pressure turbine on the inner shaft and thence to the condenser; on the inner shaft also was a small turbine, added for going astern, the steam turbine not being adapted for reversal. Steam was supplied by water-tube boilers of the express type. These vessels attained a speed of upwards of 34 knots, the revolutions of the engines approaching 1200 and the power being estimated at about 12,000 H.P. At the time of their completion these were the fastest vessels of any type afloat, but both were unfortunately lost at sea,

the *Viper* after a very short period of service being run upon the Renouquet Rock in the Channel Islands, and the *Cobra* being lost at sea on her first voyage from the contractor's works.

While the idea of the torpedo-boat destroyer originated in Great Britain, and the first boats of the type were built for the British navy, foreign Powers were not slow in availing themselves of the results obtained, and large numbers of torpedo-boat destroyers have been added to the fleets of foreign navies, the boats built by Messrs Schichau of Germany and Normand of France having especially achieved success in the attainment of high speeds on trial, while the boats of the *Bainbridge* class, built for the U.S. navy by Neafie and Levy of Philadelphia, William R. Trigg and Co., Richmond, Va., the Union Iron Works of San Francisco, and other American firms, are among the largest, fastest, and most seaworthy of the class afloat. Fig. 89 (Plate XXI.) shows the general appearance of these vessels; they are 245 ft. long, 23 ft. 7 in. wide, draw 6 ft. 6 in. of water, and have a displacement of 420 tons. Their sea-going speed is 29 knots, and their armament consists of two 18-in. torpedo tubes, two 3-pdr. Q.F. guns, and five 6-pdrs. The Japanese navy possesses in the *Niji* class (Fig. 90, Plate XXI.) a number of very fast and seaworthy destroyers. They are of approximately the same dimensions as the most recent British vessels of this type, were built by Messrs Yarrow, and obtained on trial speeds in excess of 31 knots.

Table IX. shows warships effective, building, or projected for the principal navies of the world. This table shows there are now built or projected 1346 torpedo-boats, having an average displacement of 76 tons, of which France owns 317, Russia 188, Italy 151, Germany 121, Great Britain coming fifth with 107, and of these 107 only four have been added since 1885. Further reference to this table shows that Great Britain takes the lead with torpedo-boat destroyers and torpedo gunboats in a very marked manner.

Submarine Boats.

Since about 1880 much attention has been paid by several of the naval Powers to the development of the submarine boat. The United States and France, in particular, have given special encouragement to workers in this direction; and this encouragement, combined with the fascination which the subject has for many minds, has led to the construction of a number of boats and to many experiments.

The history of the subject goes back at least 300 years, but the first undoubted success with a submarine vessel

* Displacement in some cases is approximate only.

† Including Argentine Republic, Austria-Hungary, Brazil, Bulgaria, Chile, China, Denmark, Greece, Holland, Mexico, Morocco, Norway, Peru, Portugal, Rumania, Siam, Spain, Sweden, and Turkey.

International totals { 2,578 ships. 5,317,530 tons displacement.

It will be seen that the above table does not include training ships, storeships, troopships, sloops, yachts, gunboats, vedette boats, submarine boats, and a variety of other classes. Regarding submarine boats, it may be interesting to mention that in 1902 France had 68 (built, building, and projected), Spain 2, Turkey 2, Italy 1, United States 18, and Portugal 1.

was achieved by Bushnell in America in 1775. His boat was manœuvred to the full extent contemplated in her design, and the one attempt made, as described below, to put her to practical use and sink the enemy's ship would have brought about this result if the operator had had more thought or more daring. It was worked by one man, for whom it provided just sufficient room; its general appearance, according to Bushnell's own description, bore some resemblance to two upper tortoise shells of equal size joined together, the entrance to the vessel being represented by the openings in the swellings of the shells at the animal's head; the body of the vessel was constructed of wood. The operations on board were entirely manual. By an oar in form of a screw with its spindle passing through the top the boat was sunk or raised, by another oar at the after end it was propelled; a rudder was used for guidance, and in some cases for propulsion, valves admitted water when submergence was required; and hand pumps discharged this water when it was desired to come to the surface, and a detachable weight of 200 ℔ was also supplied for emergency use. The air in the boat was capable of supporting the operator for thirty minutes; and as soon as he brought the boat to the surface, two air pipes, for discharge of foul and supply of fresh air, opened automatically. A compass, a pressure-gauge, and a sounding-line and lead were among the fittings. Behind the vessel was a large magazine containing 150 ℔ of powder, and a time-control for exploding it. From the magazine was led a rope to a wood screw at the fore part of the crown of the boat, and this screw, being worked from within, could be driven into the object to be destroyed in such a manner as to keep the magazine required for the explosion in position after it had been detached from the boat. During the War of Independence the boat was submerged beneath the British warship *Eagle*, and the operator attempted to attach the wood screw to her bottom planking: in this he failed, apparently simply because he did not let go his detachable weight and so get enough upward pressure to drive the screw into the plank. The magazine was released and exploded an hour afterwards, but at some distance from its intended position.

The problem of submarine navigation received the practical attention of Fulton during the time that he was making his experiments upon steam propulsion, and even at an earlier period. He constructed two submarine boats in France, and one in America. One of the former, the *Nautilus*, was built with the direct encouragement of Napoleon in 1801. It was supplied with compressed air for respiration, and with it Fulton conducted a series of experiments under the direction of a commission of naval officers. He descended to a depth of 25 ft., and remained under water for fully four hours, placing below a vessel provided for the purpose a torpedo by which it was blown into fragments. As with his steam engine, so too with his submarine boats, the report of the commission charged with investigation was so unfavourable that Fulton was much discouraged, and though he afterwards continued his labours in this direction, the results achieved by him were practically lost. Fulton's boat, like Bushnell's, was propelled by manual power, two horizontal screws being employed for propulsion, and two vertical screws for descending and ascending: it was built of wood with iron ribs, and was sheathed with copper.

The substitution of mechanical for hand power came later, and one of the first mechanically driven boats was the *Plongeur*, built in France in 1863 from the designs of Charles Brun. This boat had a length of 146 ft. and a diameter of 12 ft., and was propelled by an 80-horse-power compressed air engine. During the American Civil War in 1864, however, a hand-worked submarine boat 50 ft. long was employed by the Confederates. Manned by a crew of nine men, she successfully attacked the Federal ship *Housatonic*, and sank her by means of a spar torpedo, but in so doing was herself sunk. It is claimed that the loss of the boat was due to faulty handling, and not to inherent defect. Against the protest of her builder, she was immersed only to the hatch coaming; and the cover being left open, she was swamped and sunk by the wave thrown up by the explosion. It is said that this is the only submarine boat in connexion with which there is authentic record of loss of life; with her no less than three crews were drowned, in addition to the crew engaged on her last fatal expedition, so that she was the cause of the loss of thirty-six lives.

About the same time another hand-worked submarine, called the *Intelligent Whale*, 26 ft. in length and 9 ft. in diameter, attracted some attention in America. An officer, with two other persons, dived with her in water about 16 ft. deep; the officer, in diver's dress, left the boat through a manhole in the bottom, placed a torpedo under a scow, and blew the latter to pieces.

Holland's boat.

In 1875 Mr J. P. Holland produced his first plan for a submarine vessel, and in 1877 he constructed a small experimental boat, which embodied features now accepted as essentials in American design. His plan ensured that when, for the purpose of diving, water was admitted into compartments of limited size, the total weight of the boat and its contents should still be a little less than the total buoyancy. Immersion was maintained by the action of horizontal rudders, which gave a downward tendency so long as the boat had any forward motion, and there always remained enough surplus buoyancy to bring the boat to the surface on the stoppage of her propelling machinery. Any weight consumed on board was automatically compensated for by admission of water, so that the total weight remained fixed and constant; while the confinement of the water to small compartments further secured a fixed centre of gravity. The securing of these qualities of fixed weight and fixed centre of gravity is essential, and the want of them has been the cause of failure in many other designs. With the necessarily slight longitudinal stability possessed by a submarine boat, any change of centre of gravity in the fore-and-aft direction has a notable effect on the angle of trim; and such a change may readily occur, for instance, from the surging of water in a large ballast-tank not completely full. An unintentional alteration of trim when the submarine boat is being propelled involves several possible dangers: in extreme cases the crew or some of the fittings may be thrown out of position, but in any case the path of the submarine is altered, and may tend either to too great immersion on the one hand, or to breaking the surface of the water on the other. From the risk of these dangers it is claimed by Mr Holland that his design is free. The first of his boats now under discussion was steered down and up inclines by her horizontal rudders, and motive-power was obtained from a petroleum engine. The tests to which she was subjected showed that inefficiency of the engine, difficulty of vision, and trouble with the compass tended to destroy the boat's usefulness.

Nordenfelt's boat.

In 1883 Mr Nordenfelt, famous as an inventor in many directions, and especially associated with the gun which bears his name, built a submarine boat at Stockholm. She had a length of 64 ft., a main diameter of 9 ft., and a displacement of 60 tons; she was propelled by a compound surface-condensing engine indicating 100 H.P., and on a measured mile trial, not being submerged, attained a speed of 9 knots. Steam was supplied by an ordinary marine return-tube boiler, worked under forced draught, which could be fired

as long as the boat was at the surface. Storage of steam was effected at the surface, and the steam thus stored was used to drive the engine in the submerged condition. To store sufficient steam two large tank reservoirs or cisterns were connected with the boiler, and the contents of boiler and tanks (8 tons of water in all) were raised to a temperature corresponding to 150 ℔ pressure. In preparing for submergence the firing of the boiler was stopped, and the steam given off by the heated water in boiler and tanks sufficed to propel the boat for a period. The smoke was driven out through two channels, which passed round the hull and pointed astern. The material of the hull was mild steel, the frames being 3 in. by 3 in. by $\frac{3}{8}$ in., and the plating $\frac{5}{8}$ in. to $\frac{3}{8}$ in. in thickness; the depth to which she could safely descend was about 50 ft. When ballasted ready for a submerged trip, this boat showed only a very small dome for observation above the level of the water, the reserve buoyancy represented by this dome being but 1 cwt. To overcome this reserve two propellers working on vertical shafts were fitted in sponsons, one on each side of the boat, nearly amidships. These propellers were driven by a 6-horse-power engine, and drew the boat under water to the desired depth; an automatic contrivance, set in motion by the water pressure outside the boat, closing the throttle-valve when the safety limit of depth was approached. On coming to rest, the reserve buoyancy brought the boat again to the surface. When propelled by the main engines in the submerged condition, the boat was kept horizontal by means of two bow rudders operated by a plumb weight. The crew consisted of three men only, this small number rendering unnecessary the employment of artificial means of maintaining a pure atmosphere. The scheme of attack was to approach the hostile ship running at the surface until the danger of discovery was imminent, then to descend to the "awash" condition with only the dome above water, and finally to go below the surface and advance to striking distance entirely submerged, rising if necessary once or twice to allow the direction to be adjusted by observations made from the dome "awash." The weapon of offence employed was a Whitehead torpedo, carried outside on the bow and discharged mechanically. Two or three larger boats were subsequently built from Mr Nordenfelt's designs; they all involved the same principles, but were in some details made more efficient both for attack and defence.

The three main points insisted upon by the inventor were: (1) that his method of storing energy gave him a reservoir which was not liable to get out of order, could readily be repaired if necessary, and required for its manipulation no knowledge beyond that possessed by an ordinary engineer; (2) that for submergence he relied on mechanical means easily controlled, adding, as a criticism upon the alternative method of descending by steering downwards, "I need only point out the great risk of allowing an object 100 ft. long and of great weight to proceed in the downward direction even at a small angle, as the impetus gained would very easily carry it beyond a safe depth so quickly that they might not have time to check it"; (3) that the bow rudders always secured a horizontal position when the boat was running submerged, which position he had found to be a *sine quâ non* for a submarine boat.

In response to an invitation for proposals for submarines, made by the U.S. Government in 1887, designs by Holland and Nordenfelt were submitted. After much consideration the proposals of the former designer were accepted, and formed the basis of the eight boats that were built or building in the United States in 1902. From what has been already stated, the criticism of Admiral Hichborn (Chief Constructor of the U.S. Navy) will be understood when he characterizes Holland's method as a "steering-under" or "diving" device, and Nordenfelt's as a "down-haul" or "sinking" design. These two methods of obtaining submergence have each their sworn advocates, who approve of the one and disapprove of the other.

The largest boat of Mr Holland's design is the *Plunger*, which, although authorized in 1893, was not complete in 1902, a change in the surface motive-power from steam to gas having been found advisable. This boat has a length of 85 ft., diameter $11\frac{1}{2}$ ft., light displacement 154 tons, and load displacement 168 tons; she is of sufficient strength for a submergence of 75 ft., and when wholly submerged has a margin of buoyancy of $\frac{1}{4}$ ton. In addition to her horizontal rudders for diving, she has two down-haul screws, fitted in opposition to Mr Holland's recommendations; she may therefore be said to be a combination, for diving purposes, of both the Holland and the Nordenfelt designs. The *Plunger's* main engines are used for propulsion when she is navigated at the surface of the water. As originally designed, they were triple-expansion steam engines, driving triple screws, but have since been altered, as we have indicated above, to gasoline engines driving a single screw. These engines are also used for charging electric accumulators, from which alone motive-power can be obtained when the boat is submerged. The current for charging the accumulators is obtained from a dynamo of 70 H.P., which can always be run in the awash condition, and the accumulators thus kept fully charged. In the awash condition, when the boat is otherwise air and water tight, communication is kept up with the outer air by means of ducts and a smoke-pipe, the former bringing in air for combustion and respiration, and the latter carrying off deleterious products of all kinds. For submergence special fittings are used to close these ducts and pipes, and to stop the gasoline generator. The main engine is then no longer available, and for propulsion power is drawn from the accumulators, the dynamo thus becoming a motor which derives current from the accumulators, and itself drives the screw-shaft. As was the case with Mr Holland's earlier boats, great attention is given to automatic control of weights, and water-ballast is admitted to compensate for any change, such as would be produced by the discharge of a torpedo. With her original machinery the *Plunger* was to have had a surface speed of 15 knots; her anticipated speed awash or submerged is now 8 knots. To assist in determining the boat's direction a *camera lucida* is ordinarily provided, but for correcting this Mr Holland prefers trusting to observations made during occasional rises to the surface; for this purpose the boat is provided with a conning tower 4 ft. high, protected with 4-in. steel. The *Plunger* is armed with Whitehead torpedoes, and has two tubes for discharging them.

The *Holland*, a smaller boat, having a length of about 59 ft., though begun after the *Plunger*, has already been completed, and is now the property of the U.S. Government. The official report of this vessel is that "she has shown herself capable of such perfect control in the vertical plane that she may be kept whilst moving within a few inches of any desired depth, and that she may be brought to the surface and submerged again in a very short time." A good idea of the general form of the *Holland* may be obtained from Figs. 91, 92, 93, and 94 (Plate XXII.), the last three of which represent this vessel when undergoing trials to test her driving qualities.

The latest Holland design is shown in Fig. 95, which represents the design of the *Adder* and five other submarines, length 63 ft.

(By permission of "Page's Magazine.")

4 in., diameter 11 ft. 9 in.; displacement for surface running 104 tons; submerged displacement 120 tons. The main features of this class of boat are the same as have been described above for the *Plunger*, and are in essentials identical with the first five boats under construction for the British navy. The shell-plating is $\frac{7}{16}$ in. in thickness, and the frames $3\frac{1}{2}$ in. by 3 in., with a spacing of 18 in. The main machinery is a four-cylinder single-acting balanced Otto gasoline engine, which at 360 revolutions will develop 160 H.P. and give the boat a speed of about 8 knots. For propulsion in the submerged condition an electric motor is used, working at 800 revolutions, and giving a speed of 7 knots, a single left-handed propeller being employed. The current for the motor is provided by storage batteries capable of supplying 70 H.P. for 4 hours; and these batteries are charged by the main engine in a manner similar to that already described for the *Holland*. The requisite air supply is obtained when the vessel is at the surface, and is stored under a pressure of 2000 lb by a pump driven by gearing off the main engine or main motor. Air at a pressure of 50 lb is used for the expulsion of torpedoes, and the same agent, at various degrees of pressure, works the trimming and ballast tanks and some parts of the machinery; while the exhaust air from the latter subserves the purpose of ventilation. The vessel is fitted with steam and hand steering gear, and there are automatic devices for securing a constant depth during submergence. Five Whitehead torpedoes 45 cm. (about 18 in.) in diameter and 11 ft. 8 in. long are provided, and there is

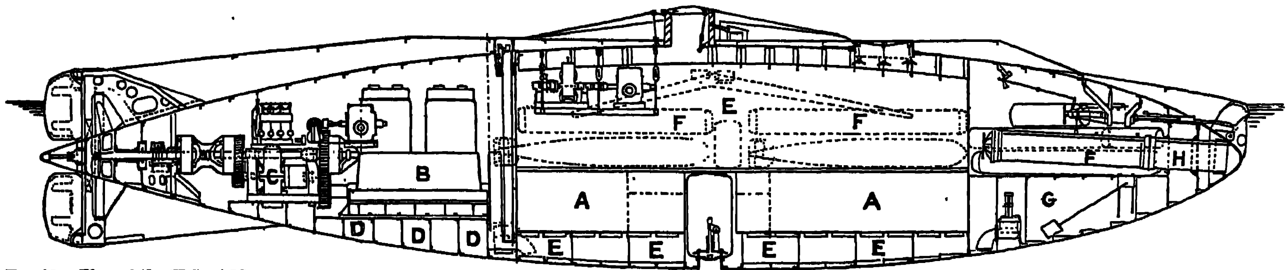

Fig. 95.—Plan of the U.S. *Adder* (reproduced by permission of Admiral Hichborn). A, storage batteries; B, gas-engine; C, dynamo and motor; D, water-tight compartments; E, main ballast tanks; F, air-flasks; G, gasoline tank; H, expulsion tube.

one expulsion tube placed forward about 2 ft. below the light water-line.

The French submarine boat *Plongeur* has already been described. A further advance in this direction was made in 1881, when a small submarine was completed by M. Goubet at Paris. An inspection of this vessel led to an order for the mechanism of a number of boats from this engineer for the Russian Government, and several sets were built and delivered early in 1883. The length of the boat constructed by M. Goubet in 1885 was 16 ft. 5 in.; it had an oval section 5 ft. 9 in. in depth and 3 ft. 3 in. in breadth, and tapered to a point at each end. A longitudinal section of the boat is represented by Fig. 96. The main portion of the hull was of bronze, cast in one piece, and at the centre of its length it was surmounted by a large dome having seven glazed openings. There was just sufficient room for an officer and a man seated back to back within it, their eyes in this position being level with the glass windows of the dome. All valves and other mechanism requiring regulation were brought within reach of these occupants, so that no movement on their part was required which might affect the trim; a reservoir of compressed air supplied the means of respiration, and an air-pump removed the vitiated atmosphere. The motive-power was furnished by accumulators, the electric energy stored therein driving a screw propeller by means of a motor. No means was provided on board of recharging these accumulators when exhausted. Submersion was effected by admitting water into tanks divided by transverse bulkheads at sufficient intervals to prevent the surging of the water in the fore and aft direction. A pump expelled this water again when desired, and a safety weight attached to the bottom of the boat was ready for detachment in the presence of danger. A pressure gauge indicated the depth of water reached, and the officer could regulate the opening of the inlet valves or the action of the pumps to maintain or vary this depth as desired. For controlling the boat in a horizontal direction a specially devised pendulum was employed, by means of which a clutch was moved, and a constantly running shaft was thrown into gear with a pump as soon as the boat departed appreciably from the horizontal plane. The action of the pump was reversible, and the clutch engaged it always in such a way that it drew water from a tank at the low end of the boat, and delivered it to a tank at the high end. Several other devices of great ingenuity were employed in the boat; notably a special form of universal joint introduced into the line of shafting. At the after end, close to the propeller, this universal joint was fitted in such a way that the screw could be set at an angle to the line of motion, and steering effected without the aid of a vertical rudder. A torpedo containing 100 lb of dynamite or other explosive was carried outside the hull, and secured by a catch joint. This torpedo, on the submarine boat being manœuvred into position, could be thrown off and allowed to rise and attach itself, by means of spikes, to some vulnerable part of the ship doomed to destruction. Retiring then to a safe distance, the submarine boat could explode the torpedo by the agency of an electric current.

Goubet system.

Working in the light of his now considerable experience, M. Goubet built several other boats. These were of larger dimensions, having a length of 27 ft.; their material was also bronze, and they were cast in three pieces, the centre one having a thickness of 1 in., while the others were reduced to a little more than $\frac{1}{2}$ in. at the ends. Possessing to a large extent the same contrivances as their predecessor, these improved boats were fitted also with an automatic apparatus for regulating the depth of submersion. In this regulator a piston is moved along a cylinder by the rotation of a rod with a screw thread cut in it, and so increases or diminishes the amount of water in the cylinder. The movement of the piston is effected by a small motor, and the direction of action of the motor is regulated by a commutator placed in juxtaposition to a pressure gauge. When the depth of submersion is too small, current is supplied to move the piston so as to admit more water; when the depth is too great, current is supplied in the opposite direction, and water is expelled. The speed attained by this boat was from 5 to 6 knots.

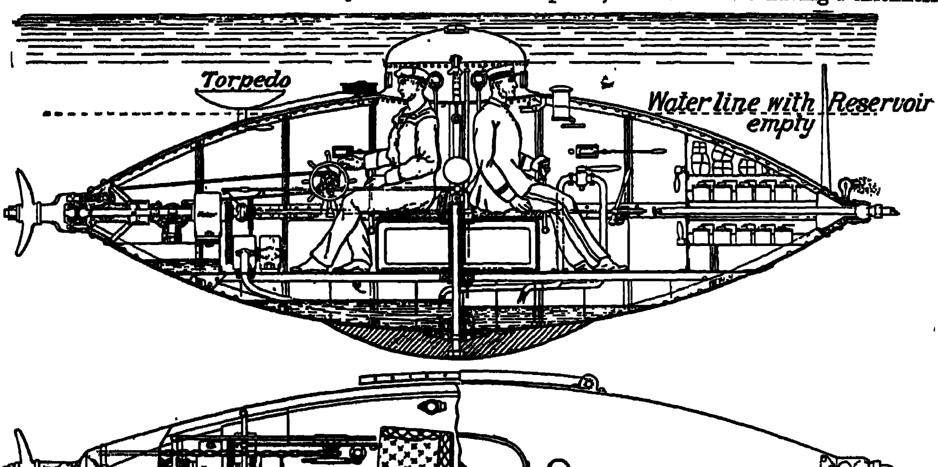

Fig. 96.—Section of Goubet submarine torpedo-boat.

The *Gymnote* was constructed at Toulon in 1888. She is a steel vessel, with a length of 59 ft. and a displacement of 30 tons;

being of an experimental character only, she has no weapon of attack. Her motive-power is obtained from accumulators, but she has within herself no means of recharging these. The maximum speed obtainable is 8 knots. For control in the vertical direction a rudder was placed aft, but this did not act satisfactorily, and was replaced by two plate rudders, movable about a horizontal axis in the middle of the boat. For the purpose of controlling the horizontal direction this boat is fitted, in addition to her vertical rudder, with a "gyrostat," the motion of which instrument is maintained by an electric motor. Previous to making a start the boat must be headed in the direction in which it is intended to move; when the gyrostat, once started, will, if not subjected to any accidental disturbance, continue to rotate about an axis invariable in direction, and any departure from this will be at once detected, whether the boat be above the surface or below it. The designs of the *Gustave Zédé* and of the *Morse* were both based on those of the *Gymnote*, the former having a length of 148 ft. and a displacement of 145 tons. In both of these the hull is of bronze; one great advantage of this metal being that, like the bronze of the Goubet boats, it is non-magnetic in character, and cannot therefore disturb the equilibrium of the compass. With their large dimensions they were intended to be formidable engines of war, and were furnished for attack with Whitehead torpedoes; of these latter they each carry three of 45 cm. (nearly 18 in.) diameter, discharging them by means of a torpedo tube. The *Morse* and the *Gustave Zédé*, like the *Gymnote*, possess only electric means of propulsion, the power being derived from batteries of accumulators. No power is provided in the vessel by which the accumulators can be recharged, so that the radius of action of these boats is necessarily very limited. A more recent boat, the *Narval* (Fig. 97, Plate XXII.), designed by M. Laubeuf, and the outcome of a general competition in 1897, has a length of 112 ft. and a total displacement of 200 tons. She was built at Cherbourg in 1898, and is furnished with a triple-expansion steam engine, obtaining its steam from a water-tube boiler of special form and heated by petroleum. As in the American submarines, this engine propels the boat when at the surface, and also drives a dynamo which recharges accumulators, the latter giving the reserve power for use in the submerged condition. A speed of 11 knots is obtained at the surface, and 8 knots when submerged. A new departure in the *Narval* is her double hull, the inner shell of which is of steel plate of sufficient thickness to resist any water-pressure to which the boat may be subjected, and the outer shell, placed at varying distances from the inner, forms a protection to the inner against attack. An armoured dome surmounts the boat, cutting through the external shell and carrying a short and narrow telescopic funnel, which, as in the case of the American boats, must be withdrawn preparatory to diving. Control in the vertical direction is obtained, when diving, by the use of two pairs of horizontal rudders, placed symmetrically—one pair forward, the other aft. By the above arrangement it is claimed that the horizontal direction of the boat is ensured, the American course of inclining the axis of the boat when diving being considered open to such grave objections that it is desirable to avoid it.

In all the more recent submarine boats of French construction much ingenuity has been directed towards obtaining instruments of vision for use when the vessel is in a steady position somewhat below the water surface. The optical tube is the instrument which has so far given the most satisfaction. A total reflection prism at the upper end of a telescopic tube is placed above the water surface, and a similar prism at the lower end of the same tube; this arrangement allows the officer in the boat to see, over a limited distance, the objects in his neighbourhood. Another instrument, the periscope, is now also employed, and has received much attention. In this an image is formed in the focus of a parabolic reflector, and can then be examined by means of an ingenious optical contrivance; but this instrument has scarcely given all the results expected of it, and in Mr Holland's boats is not used at all. American experts, indeed, place but little reliance even upon the optical tube.

Lake's "bottom-worker."

Quite a different class of submarine boats from the above is the "bottom-worker," which is represented in America by the *Argonaut*, built to the design of Mr Lake. This boat is intended for crawling over the surface of the bottom, and rather for the peaceful work of saving wrecks than for the purpose of attack, although the latter possibility has not been ignored in her conception. She consists of an underwater portion 56 ft. long, with a circular section of 9 ft. diameter; to this, for surface purposes, a superstructure has been added, with a total length of 66 ft. She is driven by a gasoline engine, and there is no storage. Ventilation is carried on from the surface, for the purposes of respiration and combustion, by two flexible tubes held up by a buoy; or, in shallow water, by pipes long enough to reach to the surface, there being also, in case of injury to these pipes, a sufficient supply of compressed air to last for some hours. For crawling purposes three wheels support the boat on the sea-bottom; two are forward and one aft, the steering being effected by the latter. Men can leave or enter the boat, by means of a door placed forward, either with or without a diving suit. The compartment to which this door belongs is kept under air-pressure sufficient to exclude the water, and is cut off from the rest of the boat by an air-lock chamber with double doors. Rising above the deck is a conning tower for observation, and at the forward end are a look-out compartment and searchlight.

Summarizing the tactical elements established by the *Holland*, Admiral Hichborn, amongst other criticisms, makes the following:—"*Control and direction in the vertical plane*—Perfectly satisfactory. *Control and direction in the horizontal plane*—Perfectly satisfactory when running on the surface; unsatisfactory when submerged, since the object to be steered for cannot be seen. Acceptable, because any predetermined direction can be held as well as can any vessel's course in a fog or on a dark night, and in the same way, *i.e.*, per compass; also acceptable because the quick rises and dives enable the helmsman readily to correct his course to intercept an off-shore enemy endeavouring to close with the shore. *Field of vision when submerged*—Nil, and therefore unsatisfactory as such; but acceptable because field of vision would carry with it the loss of the perfect invisibility which so largely adds to her effectiveness in attack, and because the quick rises and dives give perfect field of vision for a few seconds, with a minimum of chance of disablement from gun fire. *Sea-going qualities*—Perfect, since no sea, however heavy, can affect her when in the awash condition ready to dive, and when running light she can always be dropped to the awash condition in heavy weather. *Submerged motive-power*—Unsatisfactory, since its source is the heavy and cumbersome storage battery. Acceptable, since it is the most available motive-power for use when air cannot be freely used, and since the supply can always be renewed—as long as the fuel supply holds out."

In considering the possible future of the submarine boat, it appears that for such depths of submergence as were and are contemplated in any of the above-mentioned designs, there is no difficulty in employing scantlings ample for the pressures to be encountered, since the weight of hull necessitated by these scantlings introduces no abnormal difficulty into the design. The tendency at the present time is to increase the size of the boat, and what limit may be reached in this direction it is impossible to say. The greatest obstacles to progress are at present the want of satisfactory contrivances for artificial vision, and of durability in the electric storage arrangements for the requisite supply of motive-power or the substitution of a more perfect system of under water propulsion. Generally, however, it may be said that while such advances have been made in submarine construction as show that under certain conditions submergible boats may be of practical utility, they have not yet reached such a state of perfection as sensibly to modify the shipbuilding programme of great naval Powers. It is possible that for many years their value will remain moral rather than material; and their ultimate efficiency, like that of the torpedo itself, must remain in doubt until a naval war on a serious scale shall set the question at rest.

In the meantime experience seems to show that designs which provide a certain surplus buoyancy, and attain submersion by propellers or similar means, have advantages over other systems; that, under water, propulsion can be conveniently obtained by electrical motors and accumulators, and that the accumulators must be capable of being recharged by machinery in the boat, considerations of weight rendering it desirable that this machinery should be that which drives the boat in the "awash" condition. (P. WA.)

SHIPBUILDING.

THEORETICAL.

THEORETICAL shipbuilding embraces the consideration of all questions upon which the qualities and behaviour of a ship depend, and which thus determine the various features of the design. Among these are: the best size of ship to be adopted, having regard to the particular services which she will be required to perform; the requirements which must be fulfilled in order that she may make her various passages economically and with safety, in all conditions of wind and sea; the best form for the hull with regard to the resistance offered by the water at various speeds; the nature of waves and their action upon the ship; and the structural arrangements necessary in order that she may be sufficiently strong to withstand the various stresses to which she will be subjected. The determination of the best size of ship to fulfil certain conditions is one of the most difficult and at the same time one of the most important questions which have to be settled. It involves the consideration of a different set of circumstances for almost every service, and these are often so complicated that deductions from experience gained in vessels similarly employed are the only guide to be relied on, and the question is not therefore usually left wholly in the hands of the naval architect. The requirements of economical working, safety, &c., determine the length, breadth, depth, and form. The length has a most important bearing on the economy of power with which the speed is obtained; and on the breadth, depth, and height of side, or freeboard, depend to an important degree the stability and seaworthiness of the vessel. The best form for ships of high speed, their resistances at various speeds, and kindred matters of scientific interest, have been for many years the subject of experimental investigation with models—a mode of treatment which was devised and adopted by the late Mr William Froude, F.R.S., to whom the shipbuilder is indebted for very much of the trustworthy information at his disposal with regard to these matters. The stability of ships, their rolling among waves, their resistances at various speeds, and their strength, with the calculations to be made in estimating these elements, have been discussed in the ninth and previous editions of the *Encyclopædia Britannica*, and we do not propose to consider them in detail in the present article, but we add notes on the rolling and on the resistances of ships in which the results of recent investigation are given.

Rolling of Ships.

Unresisted rolling. The unresisted rolling of ships in *still* water is of no immediate practical importance, as a ship will not roll in still water unless made to do so; and even when thus set rolling, the motion cannot be unresisted, since the flat portions must experience resistance in passing through the water, and this and other causes of resistance bring about a degradation of the amplitude of rolling. The equation of motion of a ship rolling through moderate angles of inclination for which we can approximately say that the righting arm is proportional to the angle, *i.e.*, $GZ = m \times \theta$ is

$$\frac{d^2\theta}{dt^2} = -\frac{g}{\epsilon^2} m \cdot \theta \quad . \quad . \quad . \quad . \quad (1)$$

where ϵ = radius of gyration of the ship about the axis of rotation, m = metacentric height, θ = angle of inclination, and g = accelerating force of gravity. From this equation the time deduced for a single oscillation, *i.e.*, from port to starboard, or *vice versâ*, is

$$T = \pi\sqrt{\frac{\epsilon^2}{m \cdot g}} \quad . \quad . \quad . \quad . \quad (2)$$

showing that the time of oscillation varies directly as ϵ, the radius of gyration, and inversely as the square root of the metacentric height. This period, as found by calculation, is very nearly the same as the actual period observed on the ship herself when set rolling. The resistances to rolling do not sensibly affect the *period* of oscillation, but they do affect the *amplitude*. When the period is constant, *i.e.*, the time occupied in making a complete roll from starboard to port, or *vice versâ*, is the same, whatever the angle of roll, the rolling is said to be *isochronous*.

For the unresisted rolling of ships among *waves* the theory generally accepted is due to the late Mr W. Froude (see *Trans. Inst. Nav. Arch.*, 1861 and 1862). Before his work many eminent mathematicians had attempted to arrive at a solution of this most difficult problem, but for the most part their attempts met with scanty success, because wave-motion and wave-structure were imperfectly understood, and consequently the forces impressed on a ship by water in motion could not be correctly estimated. Mr Froude's theory is based on the proposition that when a ship is among waves the impressed forces on her tend to place her normal to the wave-surface. As in water at rest she is in equilibrium when her masts are normal to the surface of the water, so in waves she is in equilibrium when her masts are normal, instant by instant, to the surface of the wave that is passing her. When she at any instant deviates from this position, the effort by which she endeavours to conform herself to it depends on the momentary angle of deviation, in the same manner as the effort to assume an upright position, when forcibly inclined in still water, depends on the angle of inclination. Hence her stability, *i.e.*, her effort to become vertical in still water, measures her effort to become normal to the wave in undulating water. Mr Froude made the assumptions that the profile of the wave was a curve of sines, and that the ship was rolling broadside on in a regular series of similar waves of given dimensions and given period of recurrence. He was aware that the profile of the wave would be better represented by a trochoid, but he gave in his first paper several reasons why he preferred to retain the sine curve as the profile of the wave passing the ship. He also assumed that the ship's rolling in still water was isochronous, and that the period from one side to the other was given by $T = \pi\sqrt{\frac{\epsilon^2}{m \cdot g}}$, as above. On these assumptions, by substituting, in the equation of motion in still water, the instantaneous angle between the ship and the normal to the wave-slope for the ordinary angle of inclination, the following equation of motion is obtained:—

$$\frac{d^2\theta}{dt^2} = -\frac{\pi^2}{T^2}(\theta - \theta_1), \quad . \quad . \quad . \quad (3)$$

where θ = angle of ship's masts to the vertical, and θ_1 = angle of normal to wave-slope to the vertical at the instant considered. θ_1 has to be expressed in terms of time, and we have $\theta_1 = \Theta_1 \cdot \sin\frac{\pi}{T_1} \cdot t$, where Θ_1 = the maximum wave-slope, and T_1 half period of the wave, *i.e.*, half the time the wave takes to travel from crest to crest or from trough to trough. Equation (3) can therefore be written—

$$\frac{d^2\theta}{dt^2} = -\frac{\pi^2}{T^2}\left(\theta - \Theta_1 \cdot \sin\frac{\pi}{T_1} \cdot t\right) \quad . \quad . \quad (4)$$

which is the general differential equation of the motion of an unresisted ship in regular waves of constant period. The solution of this equation is as follows:—

$$\theta = \Theta_1 \cdot \frac{1}{1 - \frac{T^2}{T_1^2}}\left[\sin\frac{\pi}{T_1} \cdot t - \frac{T}{T_1} \cdot \sin\frac{\pi}{T} \cdot t\right] + C_1 \cdot \sin\frac{\pi}{T} \cdot t + C_2 \cdot \cos\frac{\pi}{T} \cdot t \cdot \quad (5)$$

where t dates from the mid-trough of the wave, and C_1 and C_2 are constants depending on the movement and attitude of the ship at that moment. The first term of this expression,

$$\Theta_1 \cdot \frac{1}{1 - \frac{T^2}{T_1^2}}\left(\sin\frac{\pi}{T_1} \cdot t - \frac{T}{T_1} \cdot \sin\frac{\pi}{T} \cdot t\right),$$

represents the forced oscillations imposed on the ship by the passage of the series of waves during the time t; and the second term,

$$C_1 \cdot \sin\frac{\pi}{T} \cdot t + C_2 \cdot \cos\frac{\pi}{T} \cdot t,$$

the continuance of the oscillations of the ship in still water which she had initially.

Equation (5) indicates, therefore, that the ship performs oscillations as in still water, but has superposed on these a series of oscillations governed by the wave-slope and the relation

existing between the period of the ship and that of the wave. This equation shows that there will be innumerable phases; of these, three are worthy of notice. If the initial conditions are suitably chosen (viz., ship stationary and upright at $t=0$), the second part of equation (5) will disappear, and therefore we shall first consider the forced oscillations imposed on the ship by the waves, given by the equation

$$\theta=\Theta_1 \frac{1}{1-\frac{T^2}{T_1^2}}\left(\sin\frac{\pi}{T_1}t-\frac{T}{T_1}\sin\frac{\pi}{T}t\right). \quad (6)$$

(*a*) In the case in which the ship's period in still water (T) is equal to the half period of the wave (T_1), we arrive ultimately at the equation

$$\theta=\frac{\Theta_1}{2}\left(\sin\frac{\pi}{T_1}t-\frac{\pi.t}{T_1}\cos\frac{\pi}{T_1}t\right),$$

from which we deduce (α) that at the middle height of the wave the ship's masts will have an inclination to the vertical equal to one-half the maximum wave-slope, and (β) that at each successive wave crest and hollow the range of the ship's oscillation will be augmented by $\pi/2$ times the maximum slope, so that the ship under these conditions would inevitably capsize but for the effect of the resistances and the want of synchronism.

(*b*) When $T/T_1=0$, *i.e.*, the case in which the ship is assumed to be quick in her movements, or when the period of the wave is infinitely long as compared with that of the ship, the equation (6) becomes

$$\theta=\Theta_1\sin\frac{\pi}{T_1}t;$$

that is to say, the ship will behave very much as a flat board in a seaway, so that her masts are always perpendicular to the surface.

(*c*) If we choose the initial conditions in equation (5) so that the coefficients of $\sin\frac{\pi}{T}t$ and $\cos\frac{\pi}{T}t$ are zero, then the equation will become $\theta=\Theta_1\frac{1}{1-\frac{T^2}{T_1^2}}\sin\frac{\pi}{T_1}t$; and since the slope of the wave $\theta_1=\Theta_1\sin\frac{\pi}{T_1}t$, we have the ratio of the ship's angle to the vertical to that of the normal to wave-slope to the vertical, or θ/θ_1, equal to

$$\frac{1}{1-\frac{T^2}{T_1^2}}=\text{constant}.$$

That is to say, the ship forsakes her own period and takes up that of the wave. This is termed *steady* or *permanent* rolling. Under these conditions, also, the ship's masts will lean towards the wave-crest if T is greater than T_1, and from the wave-crest if T is less than T_1. The above expression for θ is ordinarily termed the "forced oscillation," and represents the only element in rolling which strictly depends on the waves; if it be deducted from the first term of question (5) the remainder of that term with the two following terms represents a superposed "free oscillation" in the ship's natural period, which depends on accidental circumstances.

Mr Froude in his first paper further showed how the successive angles of a ship's rolling may be exhibited graphically, and he touched on the influence of resistance in reducing rolling. The following is the summary he gave of the conclusions he reached:—

"(i.) All ships having the same 'periodic time,' or period of natural roll, when artificially put in motion in still water, will go through the same series of movements when subjected to the same series of waves, whether this stability in still water (one of the conditions which governs the periodic time) be due to breadth of beam, or to deeply stowed-ballast, or to any such peculiarity of form as is in practical use.

"This statement would be almost rigorously true if the oscillations were performed in a non-resisting medium, or if the surface-friction and keel-resistance, by which the medium operates to destroy motion, were of the same equivalent value for all the ships thus compared. It requires, however, to be modified in reference to the circumstance that of two ships having the same periodic time in still water, the comparative forms may be such that the one shall experience such resistance in a higher proportionate degree than the other, and the necessary modification may be expressed in terms of their relative behaviour when set in motion in still water. The vessel which is the more rapidly brought to rest by resistance in still water will in the greater degree resist the accumulations of angle imposed on her by consecutive wave-impulses, and will the more fall short of the maximum angle which both would alike attain if oscillating in a non-resisting medium.

"(ii.) The condition which develops the largest angles of rolling is equality in the periodic times of the ship and of the waves; and this is true alike for all ships, whether their scale of resistance, as above referred to, be large or small.

"(iii.) That ship will fare the best which, *cæteris paribus*, has the slowest periodic time.

"(*a*) The waves which have a periodic time as slow as hers will have a greater length from crest to crest than those of quicker period; and, on the whole, long waves are relatively less steep than short ones. Now it is the steepness of the waves in a wave-series, not their height simply, which governs the rate at which angles of rolling will accumulate in a given ship when exposed to it.

"(*b*) Of two ships one of which has periodic time rather slower than the waves in a given ratio, the quicker ship will accumulate the larger angles.

"(*c*) It will require a heavier or a more continued gale to rear waves which have the lengthened period.

"(*d*) When the gale has continued so long that the largest waves have outgrown the period of the ship, she will not thereby have been released from the operation of waves having her own period, since the larger waves carry on their surface smaller waves of every intermediate period (this, at least, I believe to be the case).

"(*e*) When the gale has ceased and the sea is going down, the slower the period of the ship the sooner she will be released from waves of as slow a period.

"(iv.) There are two, and only two, methods of giving a slow period to a ship.

"(*a*) By increasing her 'moment of inertia,' as by removing her weights as far as possible from her centre of gravity; an arrangement which for the most part can only be accomplished to a limited extent.

"(*b*) By diminishing her stability under canvas. This can always be accomplished in the construction of a ship, and generally in her stowage, to any degree consistent with her performance of her regular duties, by simply raising her weights. Were we to raise these so high as to render her incapable of standing up against the action of the wind on her sails, the steepest waves would pass under her without putting her in motion.

"Thus the enormous weights carried by the armour-plated ships, extended laterally to the greatest possible distance from the centre of gravity, and raised high above it, serve in both respects to moderate, not to enhance, this tendency to roll; and when it is said that with the weights thus placed, and once put in motion, a ship 'must roll deep (deep, though easy),' it should be remembered that those very relations of force and momentum, which show how difficult it must be to check her motion when once it has been impressed on her, show also that it must be equally difficult to impart that motion to her in the first instance. The difficulty of starting her has a priority in point of time over the difficulty of stopping her, and prevents it from being felt by limiting the motion which would have called it into play.

"(v.) The conditions which govern pitching may be noticed here, though they have not been discussed in the paper.

"Were it possible, by concentrating her weights or by extending her plane of flotation, to give to the ship a period indefinitely quick for both longitudinal and transverse oscillations, as compared with that of such waves as are large enough to put her in motion, she would acquire no cumulative oscillation, but would float always conformably to the mean surface of the wave which passes under her.

"But this condition, which is so unapproachable in practice in reference to transverse oscillations that the attempt to approach it will but develop the evils pointed out in (iii.), is of necessity so closely approached in practice in reference to longitudinal oscillations, that those evils can only be escaped by approaching it as closely as is possible. The plunging of a ship whose weights are extended far fore and aft is but an incipient development of those phases of oscillation which have their proper development in transverse motion only. The best that can be desired in reference to longitudinal motion is that the ship's period, for longitudinal oscillation, shall be as quick as possible, and her position always as conformable as possible to the mean surface of the passing waves.

"I have insisted here, more prominently than in the body of the paper, on the circumstance that a total loss of stability, using that word in the ordinary sense of power of carrying sail, implies the possession of absolute stability, as regards rolling motion due to wave-impulse, because it has been pointed out to me that the attention of readers should be more strongly directed to it, not indeed as representing a practically available possibility, but as serving best to force the mind, by contact with an extreme conclusion immediately deducible from the theory, to appreciate its fundamental principles. And the proposition thus certainly furnishes a crucial test of whether the principles have been appreciated or not, and it supplies also a ready means of testing the theory by a crucial experiment. I must, in addition, express my own confident belief that any one who will try the experiment fairly will find the proposition so fully verified that he will feel obliged to admit that the theory which leads to so paradoxical yet true a conclusion deserves at least a careful study. But the more practically useful aspect of the theory is that which presents to view the varying phases of cumulative oscillation which a ship tends to undergo when exposed to various types of wave-series; the phases depending on the relation which her natural period of

rolling, when set in motion in still water, bears to the period of wave-recurrence, and on the maximum steepness of each individual wave of the series—phases, in fact, which she would actually undergo but for the effect of surface-friction and keel-resistance; the nature and value of which conditions, as well as the nature and necessity of experiments for their determination, have been pretty fully dealt with in the body of the paper.

"I will here only add a synoptical statement of the principal features of those phases, given in a rather more complete form than in that part of the paper which referred to them, though they are pretty fully exhibited by the diagrams.

"By a 'complete phase' is meant that series of oscillations which the ship undergoes counting from the time when, for a moment, she is stationary and upright in a similar position, and is about to recommence an identical repetition of the movements she has just completed.

"For the benefit of those who may glance at the appendix before they read the paper, I will mention that T is the number of seconds occupied by the ship in performing a single oscillation in still water, starboard to port, or *vice versâ*. T_1 is the number of seconds occupied by the wave in passing from hollow to crest, or crest to hollow. Θ_1 is the number of degrees in slope of the steepest part of the wave; and p/q is the ratio T/T_1, with the numerator and denominator converted into the lowest whole numbers that will express the ratio, where, however, it must be noticed that for $T/T_1 = 1$, p/q must be taken as the limit of such a form as $\frac{999999}{1000000}$. Then—

"(i.) The ship will complete the phase in the time $= 2qT$.

"(ii.) In completing the phase the ship will pass through the vertical position $2p$ times, or $2q$ times, according as p or q is the smaller number.

"(iii.) The ship will pass through the vertical position at the middle of the phase.

"(iv.) On either side of the middle of the phase there must occur, as equal maximum oscillation, the maximum in the phase, say Θ, which will approximately (but never in excess) $= \pm \Theta_1 \frac{q}{q-p}$.

"(v.) From these propositions it appears that if we compare two cases, in one of which the value of T/T_1 is the reciprocal of its value in the other, the phase will in each case consist of the same number of oscillations similarly placed; but in that one in which the period of the wave is slower than the period of the ship, the angles of oscillation will be the larger in the ratio p/q or q/p, whichever is the greater. The following table expresses the results of the above propositions, as exhibited in the diagrams, based on the assumption that the period of the ship is in every case $T = 5''$, and that the maximum slope of the wave $\Theta_1 = 9$ degrees:—

Ship's Period, or T.	Wave's Period, or T_1.	T/T_1.	T/T_1, reduced to Lowest Whole Numbers $= p/q$.	Time of Complete Phase $= 2qT$.	No. of Times Ship passes Vertical Position during Phase.	Approx. Outside Value of Θ, the Maximum Angle reached during Phase.
5″	5″	1	$\frac{999999}{1000000}$	Infinite.	Infinite.	Infinite.

5″	2·77″	1·8	$\frac{9}{5}$	50″	10	11 ,,

It should be noted that the "wave-slope," spoken of as regulating the rolling, is not precisely the surface-slope, but a slope somewhat less (according to the depth of the ship), in virtue of the diminution of wave-motion with depth below the surface.

We have up to the present assumed that the rolling of ships in still water and among waves is *unresisted*, but this is not the case. A ship, if set rolling in still water, will experience resistance to the rolling motion, and a degradation of the amplitude will take place until the ship finally comes to a position of rest. Similar forces operate when a vessel is rolling among waves.

Resisted rolling.

The earliest investigators of resisted rolling in *still* water were Mr Froude in England and Messrs Bertin, Dubil de Benazé, Risbec, and Antoine in France. The method adopted was to roll a ship in still water and observe how the amplitude decreased roll by roll. As large an initial angle of roll as possible was obtained, generally by making men run from side to side of the ship, their runs being so timed as to add to the angle of roll swing by swing until the maximum angle was reached. This angle obtained, all movement on board was stopped, and the ship allowed to roll freely of herself until she came to rest. During this free movement a complete record of her angular motion against time was registered by means of a short-period pendulum and an electric timer. From this record a curve was constructed, in which abscissæ represented number of rolls and ordinates extreme angles of roll to one side of the vertical. Such a curve is termed a curve of "declining angles."

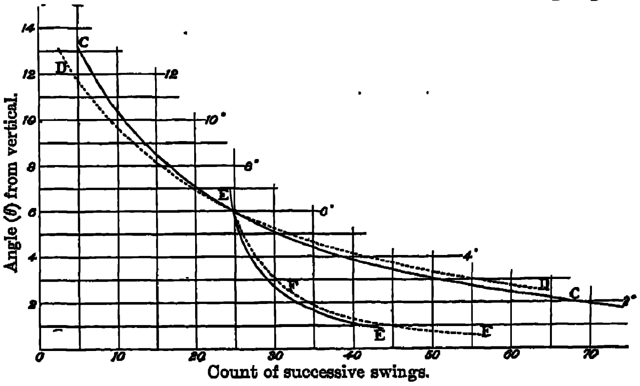

FIG. 1.—Curves of declining angles. C, light, and D, deep draught, no bilge keels; E, light, and F, deep draught, with bilge keels.

From this curve another curve is constructed, in which the abscissæ represent angles of roll and the ordinates the angle lost per swing. Such a curve is termed a "curve of extinction." Figs. 1 and 2 give these curves as obtained from experiments on H.M.S. *Revenge*; they are taken from a paper by Sir W. H. White, read before the Institution of Naval Architects in 1895.

Having obtained such curves, Mr Froude proceeded to investigate the relation between the degradation of the amplitude and the resistances which cause it. He assumed that the resistance to rolling varied (1) as the angular velocity, and (2) as the square of the angular velocity, and with these assumptions he obtained the following differential equation for the curve of extinction:—

$$-\frac{d\theta}{dn} = a \cdot \theta + b \cdot \theta^2,$$

where θ = extreme angle reached at any particular oscillation, n = count of the number of oscillations from the start of free rolling, and a and b are coefficients which bear a direct relation to the coefficients of resistance assumed to vary as the angular velocity and the angular velocity squared. Mr Froude assigned his reasons for expecting the resistance to vary partly as the first and partly as the second power of the angular velocity. The latter he considered due to surface-friction and the head-resistance of keels and deadwood, and the former to the resistance caused by the creation of a small wave each roll, which by travelling away from the ship becomes the cause of a dissipation of energy.

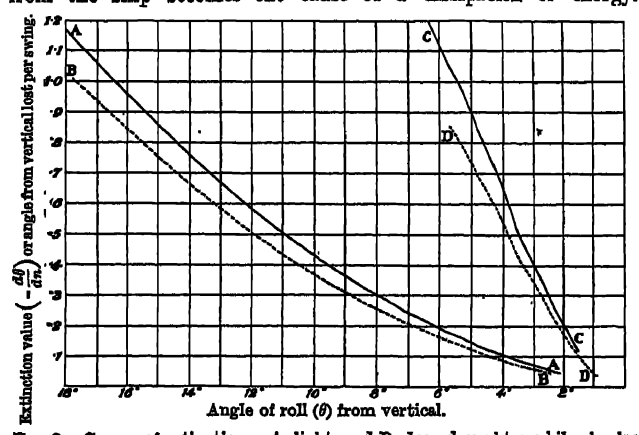

FIG. 2.—Curves of extinction. A, light, and B, deep draught, no bilge keels; C, light, and D, draught, with bilge keels.

Froude's views have been confirmed by the accuracy with which the expression $-\frac{d\theta}{dn} = a \cdot b + b \cdot \theta^2$ may be made to fit the curve of extinction of practically any ship by the judicious selection of the coefficients a and b. M. Bertin has, however, wished to substitute an expression equivalent to $-\frac{d\theta}{dn} = b \cdot \theta^2$, chiefly because he was not satisfied as to the mechanical conditions expressed by the other term. Other French investigators, again, have preferred an expression equivalent to $-\frac{d\theta}{dn} = a \cdot \theta$, but in Great Britain Mr Froude's expression has always been accepted as best representing all the facts.

For the *Revenge* the following equations represent the curves of extinction given in Fig. 2:—

For *deep draught*—

without bilge keels $-\frac{d\theta}{dn} = \cdot 0123\theta + \cdot 0025\theta^2$;

with ,, ,, $-\frac{d\theta}{dn} = \cdot 065\theta + \cdot 017\theta^2$.

For *light draught*—

without bilge keels $-\frac{d\theta}{dn} = \cdot 015\theta + \cdot 0028\theta^2$;

with ,, ,, $-\frac{d\theta}{dn} = \cdot 084\theta + \cdot 019\theta^2$

(θ in all cases being measured in degrees and not in circular measure).

The large increase in the b coefficient after bilge keels had been fitted has given rise to considerable discussion. Mr Froude had experimented with a deeply submerged plane oscillating in water, and he found that at a speed of 1 foot per second the resistance per square foot was 1·6 lb. Using this figure to calculate the work per swing (from an extreme angle of 6 degrees), the head-resistance of the bilge keels is found to be about one-fourth the energy lost in a single swing, due to the increased value of the b coefficient in the above formula. Thus the energy abstracted in this particular case is about four times what can be theoretically traced to the head-resistance of the bilge keels. This discrepancy has been observed in many previous cases, and it appears that when bilge keels are added to a ship they become effective, not merely as flat surfaces moving with the ship and experiencing direct resistance, but also by indirectly influencing the stream line motions which would exist about the oscillating ship if there were no bilge keels. In this connexion reference must be made to a paper by Professor Bryan, read before the Institution of Naval Architects in 1900, on the "Action of Bilge Keels."

The problem of resisted rolling among *waves* Mr Froude attacked in an inverse manner, to ascertain "what wave-series is required to keep the given ship at a given range of steady rolling with any assigned period, including the effect of resistance." Subsequently the problem was treated in a direct manner by the process of "graphic integration." This process is a most exact method of determining the motion of a ship, having given the elements of the ship's rolling in still water and the wave-series that is acting upon the ship, it enables the subsequent motion to be completely determined (see *Trans. Inst. Nav. Arch.* 1875). Some most valuable developments of the process were made by Sir William White in a paper read before the same society in 1881 on the "Rolling of Sailing Ships," in which the action of the wind on the sails, and the variation of the virtual weight of the ship on the wave are included. The effect of wind-pressure in heeling a ship is very much greater when she is at the crest of a wave than when she is at the trough, because her virtual weight is less. This must be taken account of in dealing with sailing vessels, the reduction of virtual weight, and therefore of righting moment, at the crest of a wave being very considerable, though the heeling moments due to the wind suffer no such reduction. We have seen above that when the half-period of the wave-series affecting a ship is equal to the period of the ship ($T_1 = T$), then at each successive wave crest and hollow the range of the ship's oscillation (unresisted) will be augmented by $\frac{\pi}{2}\cdot\Theta_1$, where Θ_1 is the maximum wave-slope. If, however, under these circumstances, the ship settles down to a steady roll of amplitude Θ, we can say that the increase of amplitude due to the wave is exactly balanced by the effect of the resistance to the rolling. The decrease of amplitude in still water per roll due to resistance is given by $-\Delta\theta = a\cdot\theta + b\cdot\theta^2$, and for the angle Θ will equal $a\cdot\Theta + b\cdot\Theta^2$. We can therefore equate these two quantities, and say $\frac{\pi}{2}\cdot\Theta_1 = a\cdot\Theta + b\cdot\Theta^2$, where Θ_1 = angle of maximum wave-slope and Θ = angle of steady rolling. With M. Bertin the equation would be

$$\frac{\pi}{2}\cdot\Theta_1 = N\cdot\Theta.$$

In 1894 and 1895 M. Bertin, at the Institution of Naval Architects, extended this relation to cases in which T_1 is not equal to T, obtaining at the same time not simply the angles of steady rolling for these cases, but the maximum angles passed through on the way to the steady condition; to these maximum angles he gave the name of "apogee" rolls. Mr R. E. Froude in 1896, at the I.N.A., investigated the probable maximum amplitude which she would attain under the influence of a non-synchronous swell if started with no roll. To arrive at the value of this "criterion amplitude," as he called it, Mr Froude superposed upon the steady resisted "forced oscillation" proper to the waves (which is easily calculated), a resisted "free oscillation" of equal initial amplitude, so that the two oscillations should at the start cancel one another and give no roll. For this supposition the mathematics readily give all the subsequent angles of roll. This treatment in effect assumes a curve of extinction such that the loss of roll per swing is proportional to the angle of roll; but provided the coefficient of extinction taken in the calculation was made to agree with the actual extinction at the angles mainly in question, little error was found to arise from the incorrectness of this assumption.

The following table shows the difference between the "criterion angle" and the angle of steady roll in the case of the *Revenge*, both without and with the bilge keels, and with the assumptions above mentioned:—

Maximum Wave-Slope, 3 Degrees.								
	$\frac{T}{T_1}$ = 1·3.		$\frac{T}{T_1}$ = 1·2.		$\frac{T}{T_1}$ = 1·1.		$\frac{T}{T_1}$ = 1·0.	
	Criterion Angle.	Angle of Steady Roll.	Criterion Angle.	Angle of Steady Roll.	Criterion Angle.	Angle of Steady Roll.	Criterion Angle.	Angle of Steady Roll.
	deg.	deg.	deg.	deg.	deg.	deg.	deg.	deg.
Revenge (deep draught), with no bilge keels	8·25	4·35	12·25	6·8	21·2	13·9	41·1	41·1
Revenge (deep draught), with bilge keels .	6·6	4·24	8·6	6·4	11·55	10·8	14·85	14·85

Mr Froude in his paper gives a number of instructive diagrams, from which he draws the conclusions that, however non-uniform initially, the rolling ultimately falls into the uniform forced oscillation; that it does so the sooner, *cæteris paribus*, the higher the resistance, and with the fewer "cycles" or alternations of amplitude of rolling, the more nearly synchronous the swell with the ship; that the amplitude of the ultimate uniform rolling is an approximate mean of the alternate maxima and minima of the precedent non-uniform rolling; that if the rolling starts from zero, the maximum amplitude falls short of twice the ultimate uniform amplitude, the more so the higher the resistance and the more synchronous the swell; and that in a synchronous swell the maximum amplitude cannot exceed the ultimate uniform amplitude, unless it does so initially. In two remarkable papers by Captain and Professor Kriloff of St Petersburg, read before the I.N.A. in 1896 and 1898, the whole motion of a ship, including pitching and rolling, is dealt with; these papers aim at taking account of every variation which can reasonably be conceived.

Bilge keels.

An extremely important practical matter very closely related to rolling is the effect of bilge keels. Some reference has already been made to these and the influence they exert on the rolling of a ship in still water, as illustrated by H.M.S. *Revenge*, in which there was one bilge keel on each side, 200 ft. in length and 3 ft. in depth, tapered at the extreme ends. The great value of bilge keels in diminishing rolling had been known as early as 1872, when Mr Froude experimented with the *Perseus* and the *Greyhound*, alike in every essential respect except that the former was not provided with bilge keels and the latter was. The general conclusion in this case was that the rolling of the *Greyhound* was only about one-half that of the *Perseus*.

Bilge keels were usual in warships until, in the design of the *Royal Sovereign* class, it was decided not to fit them, owing to the large dimensions of the vessels and the difficulties in certain circumstances of docking them if provided with bilge keels. Ultimately one of the class, the *Repulse*, had them fitted for purposes of comparison, and the result was so marked that it was resolved to fit similarly all the ships of the class. Before doing the work on the *Revenge* a careful programme was drawn up of experiments to be made before and after the bilge keels were fitted, and by carrying out this programme very valuable results were obtained. The experiments were made at Spithead in smooth water, and the general effect of the bilge keels was found to be the reduction of the rolling to one-third its former amount. When instead of having no motion in the line ahead the ship had a speed of 12 knots, the effect was even greater.

The experience of Great Britain with regard to bilge keels has been largely repeated in America. In the ships of the U.S. navy bilge keels were omitted for much the same reasons as in the *Royal Sovereign* class; then on the U.S.S. *Oregon* they were fitted, experimental investigation being made both without and with them, and the general conclusion arrived at was that the rolling was diminished to one-third by the bilge keels. The usual form of bilge keels fitted to warships to reduce rolling may be seen in Fig. 30.

As an alternative to bilge keels, water chambers at one time promised great results in the way of reduction of rolling. The effect of such chambers, with some numerical results, is described very fully in the ninth edition of this work. Exigencies of space

have, however, prevented them from becoming a permanent feature in the design of war or other ships; in addition, the conditions of warship design have changed, and now admit of more moderate values of the metacentric height, which is a most important factor in increasing the time of oscillations and thus reducing rolling.

Resistance and Propulsion.

The resistance and the propulsion of ships are dealt with at considerable length in the ninth edition of this work, and the account given should be read in connexion with the following notes.

By means of experiments with models of different sizes towed by a steam launch, Mr W. Froude established the truth of his "law of comparison" between vessels of different size, a law which he had conceived independently, but which had been previously worked out on mathematical lines by M. Reech in his *Cours de Mécanique*, published in 1852. He afterwards, in 1871, constructed a tank and apparatus at Torquay for dealing with these matters on behalf of the British Admiralty. When in 1885, six years after his death, the ground occupied by the Torquay tank was required for building purposes, a new tank was constructed at Haslar, near Portsmouth, from the designs and under the supervision of Mr R. E. Froude, F.R.S., such improvements being added as experience at Torquay had showed to be desirable. At both these tanks models of propellers as well as of ships were experimented upon, besides a variety of matters connected with the general subject. Similar Government establishments have since been established in Holland, Italy, France, Russia, and the United States, and by one private firm on the Clyde (William Denny and Brothers, Dumbarton). Others are in contemplation. The Admiralty experimental tank at Haslar is nearly 400 feet long, 20 feet wide, and 9 feet deep. The main experimental carriage spans the whole width of the tank, and carries a secondary railway on which the subsidiary carriages, which carry the experimental apparatus of different kinds, are adjusted in position. The main carriage runs on rails on the side walls, and can travel the whole length of the tank; it is driven at various speeds by a wire rope from a stationary engine of ample power. Ordinary speeds range from 100 to 800 feet per minute, while an extreme speed of 1200 feet per minute can be obtained; the speeds are regulated by a highly sensitive governor. The models are made of hard paraffin-wax, generally about 14 feet long and somewhat over one inch in thickness; they are cast in a mould, with an allowance of about $\frac{1}{8}$ inch for finishing. To shape a model accurately, it is placed bottom up on the bed of a machine in which a pair of revolving cutters, one on each side of the model, cut out on its surface a series of level lines, whose contours are precisely similar to those on the drawing of the ship whose model is under treatment. When all the level lines have been cut in, the model presents the appearance of a series of steps, the bottom angles of which correctly represent the true form the model should possess. The paraffin ridges between these level lines are trimmed off by the use of suitable tools, and the outside surface made quite smooth with flexible steel scrapers. When ballasted to its required displacement and saddled with a frame, which carries the guiding attachment and also the towing-rod, the model is placed below the dynamometer carriage, and the dynamometer is lowered into place. The towing-rod at its forward end is then in a position to impart horizontal forces by a hard steel surface to a knife-edge on the dynamometer lever within the model at about the level of the water-surface. There are various delicate arrangements with knife-edge adjustments, which result in the horizontal forces being transmitted through a spiral spring, the extensions of which are multiplied by a lever and recorded by a pen on a paper-covered cylinder, distances and time being simultaneously recorded. From these elements, the speed and resistance corresponding to each experiment are deduced, a most necessary condition being that the speed shall be uniform throughout each experiment. By somewhat similar arrangements on another subsidiary carriage, the action of model screw propellers is tested, either in undisturbed water or behind a model, the rate of rotation, rotary resistance, and thrust being measured.

Experimental tanks.

One of the most recent experimental tanks is that constructed by the United States Government at the Washington Navy Yard. The building is 500 feet long and 50 feet wide inside; the breadth of the water-surface is 43 feet, the length 470 feet, 370 feet of which has a depth of about 14 feet. The models are constructed of wood and not of paraffin, in consequence of the high temperatures reached at Washington in summer. The models are made by a copying machine adapted for the purpose; after removal from the machine a little finishing by hand is necessary, and over the finished surface a waterproof varnish is applied. The carriage to which the model is attached for the purpose of experiment runs upon four pairs of wheels and spans the entire breadth of the basin; it is driven electrically, one motor being applied to each pair of wheels; the speed is controlled by a delicate governor on the generator. The possible speeds obtainable range up to 20 knots. In the dynamometric apparatus electricity is also used, and multiplying levers, as used by Mr Froude, are entirely dispensed with, whenever it is desirable to avoid friction. Resistance is measured by the extension of a spring, as usual, and several ingenious arrangements have been devised to obtain the recorded results.

Mr W. Froude, basing his investigations partly on theory and partly on the results of experiments, found that in a body moving with uniform speed through water at, or near the surface, the resistance would consist of three parts: (1) surface friction; (2) eddy-making resistance, chiefly due to rapid changes of form, especially towards the after end; (3) wave-making resistance, due to the expenditure of energy in continually supplying the waste of the attendant system of waves. For some purposes it is convenient to group (2) and (3) together under the name of residuary resistance—that is, the resistance left after deducting surface friction.

Components of resistance.

Surface friction is of great importance, as it forms the chief cause of resistance at relatively low speeds, and a considerable proportion of the total even when the speed is high. It necessarily varies with the area and nature of surface exposed, and with the speed through the water; it also varies with the density, but not with the pressure, and is therefore practically independent of the depth below the surface. Formerly it was thought to vary directly as the area and the square of the speed. Mr W. Froude's experiments demonstrated that the resistance per square foot diminishes somewhat as the length of the surface is increased, and with varying speeds its variation is expressed in most cases by a less exponent than the second power. Thus for a surface covered with fresh clean paint 2 feet long in the direction of motion, at 600 feet per minute, the resistance is 0·41 ℔ per square foot, and it is varying as the second power of the speed. For the same surface 50 feet long in the direction of motion, the resistance is only 0·25 ℔ per square foot, varying as the 1·83 power of the speed.

With regard to the second form of resistance, that due to the formation of eddies, Mr W. Froude spoke of it as hindering the necessary stream-line motions, altering their nice adjustment of pressures and velocities, defeating the balance of forward and backward forces acting against the surface of the body, and thus inducing resistance. This view was extended by Mr R. E. Froude in 1894, in a paper read before the Greenock Philosophical Society. In speaking of the stream-line motion of a submerged body, he says: "Along the sides and at the shoulders of the body the particles in a frictionless fluid have a defective pressure and a corresponding excess of speed. In a frictional fluid the case will be the same so far as pressure is concerned. But in respect of speed the case will differ in this way, that near the surface of the body the particles will have their speed reduced in consequence of the skin friction, thus embodying what is called the frictional wake. Now, how are these particles of reduced speed to continue their flow against the rise of pressure between the low-pressure region at the shoulder and the high-pressure region at the stern? In the frictionless fluid the particles do so in virtue of their excess of speed, which they exchange for pressure; but what is to become of the particles near the side in the frictional fluid, which have already lost a great deal of their speed? They, in advancing into the high-pressure region, will render up what speed they have left, till they are bankrupt altogether in the matter of speed, and then tend to stop still." Pursuing this line of argument, he (1) shows that this disturbance of stream-line speed introduces quite other conditions of flow than pure stream-line conditions, and (2) explains why given abruptness of form is far more potent as a disturbing cause when it is situated near the stern than when near the bow.

With regard to the third form of resistance, namely, that due to the formation of waves, it is important to note that although it is of small importance at relatively low speeds, yet for high speeds it forms a considerable portion of the total. The rapid growth of resistance as the speed is increased, and consequently the large increase of horse-power for an increment of speed at high speeds, compared with that caused by a similar increment at low speeds, is due to the resistance caused by the formation of waves. In the motion of water past a body submerged deep enough below the surface to avoid wave-making, a portion at the forward end encounters increased pressure, due to the motion; a succeeding portion encounters decreased pressure; and the after portion, increased pressure again. In a frictionless fluid the sum of all these pressures resolved in the line of motion would be *nil*; there would be no resultant force on the body, due to the fluid being pushed aside at the front and closing in at the rear. With the body near the surface, and still more with the body only partially immersed, as a ship, the excesses of pressure at the ends, and the defects of pressure along the sides, due to the motion, have the immediate effect of causing the level of the water to be raised at the ends and lowered along the sides. In the case of a ship moving on the surface of water supposed to be still, these variations of pressure will still exist, and the imaginary statical wave, first mentioned by Mr R. E. Froude in his lecture before the Greenock Philosophical Society in 1894, would be their natural result. In this imaginary

wave "the elevations and depressions are the statical equivalent of the differences of pressure which there would be if the surface were forcibly kept smooth, as it might be conceived to be if the underwater hull were travelling beneath a rigid sheet of ice." This statical wave may be regarded as the cause of the actual wave-series we observe. Any disturbance of level in water tends to generate a series of waves, and so we have the bow series of waves, caused by the statical wave at the bow, and the stern series of waves, caused by the statical wave at the stern. The force required to maintain continually these waves is the measure of the wave-making resistance of the ship.

Each of these series of waves consists of a set having their crests nearly perpendicular to the line of motion, and a diverging set sloping aft. These latter pass at once away from the ship after being formed, but the transverse series initiated at the bow cause considerable interference with the corresponding series at the stern. The resulting total energy of the wave-field will vary according to the way in which the two series interfere with each other, so affecting the resistance of the ship. This is the cause of the series of humps and hollows which has been noticed as a characteristic feature of a curve of resistance on base of speed. This was investigated by Mr W. Froude in his 1877 paper before the I.N.A. on the effect produced on the wave-making resistance of ships by varying the length of the parallel middle body; the matter of this paper is given in considerable detail in the ninth edition of this work. It became apparent from his experiments that a hump on the resistance-curve was due to the incidence of a crest of the bow-wave series on the crest of the stern wave, while a hollow on the resistance-curve was due to the incidence of a trough of the bow-wave series at the same place.

The form taken by the waves generated in the motion of ship models has been carefully observed by both Mr W. and Mr R. E. Froude. To the peculiar arrangement of the crests of the diverging waves has been given the name *échelon*—the arrangement, namely, by which the most highly raised portions stand in ridges, each stepped back from the line of the crest of its preceding neighbour, the line again connecting the summits of these successive crests forming a definite angle with the line of motion of the body. The true meaning of this *échelon* series has been pointed out by Lord Kelvin; he has shown that it arises from the same cause as the transverse series, the two series being both parts of a complete whole.

Experimental results. Of the enormous number of experimental results that have now been obtained from the trials of ships models, in the tanks referred to above, remarkably few have been made public. In connexion with the Torquay and Haslar tanks some few of the reports by Mr W. and Mr R. E. Froude have been published by order or permission of the Board of Admiralty, chiefly through the I.N.A. and other societies. Amongst these may be mentioned the *Greyhound* experiments in 1873; the *Merkara* results, in an I.N.A. paper in 1876; experiments on the effect produced on the wave-making resistance of ships by varying the length of parallel middle body, in an I.N.A. paper in 1877; results obtained from models of three merchant liners in 1881; and a paper before the I.N.A. in 1888 on the "constant" system of notation of results of experiments on models used at the Admiralty experiment works. Of the Dutch results a number were published by the late Dr Tideman in the *Memorial van de Marine* in 1878. Of the Dumbarton experiments, results for three vessels were given by the late William Denny to the Institution of Engineers and Shipbuilders in Glasgow in 1884; and for two models at varying draughts by Mr A. Denny at the International Engineering Congress at Chicago in 1893. The results of some experiments at the Italian tank to ascertain the effect of depth of water on resistance were communicated to the I.N.A. in 1900 by Major Guiseppe Rota, and in the discussion Mr A. Denny gave the results of some similar experiments carried out at Dumbarton.

The experiments with the *Greyhound* were of special importance, as they helped materially to confirm the accuracy for practical purposes of the "law of comparison." In this case dynamometric experiments were made on the ship as well as on her model. Three different displacements were given to the ship, and for the least and greatest of these several different conditions of fore-and-aft trim were tried. Subsequently, also, the vessel was fitted with bilge keels. Resistances at various speeds were obtained for no less than eleven different conditions of the vessel. The model was on a scale one-sixteenth full size, and the resistances were obtained in the Torquay tank under each of the conditions of displacement and trim corresponding to those adopted in the ship herself. Very close agreement was found to exist between the resistances of the *Greyhound* and her model according to the "law of comparison." (This most important law is very fully dealt with in the ninth edition of this work.) The *Merkara* results are of special interest, because of Mr W. Froude's attempted

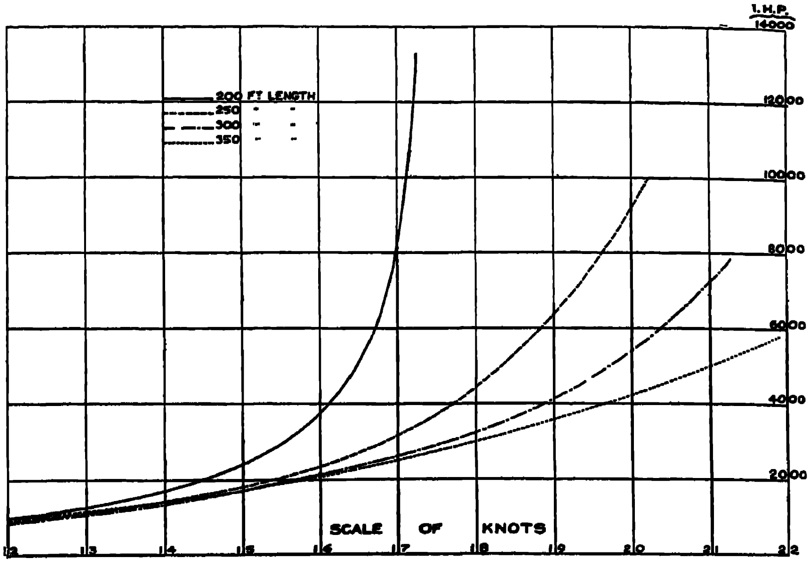

FIG. 3.—Curves of I.H.P. for a vessel of 2000 tons displacement.

analysis of the "indicated thrust" curve into its elements. Besides the curve of I.H.P. on base of speed, another curve was constructed showing "indicated thrust" on the speed base. This "indicated thrust" was obtained at any given speed by multiplying the I.H.P. by 33,000 and dividing by the product of pitch

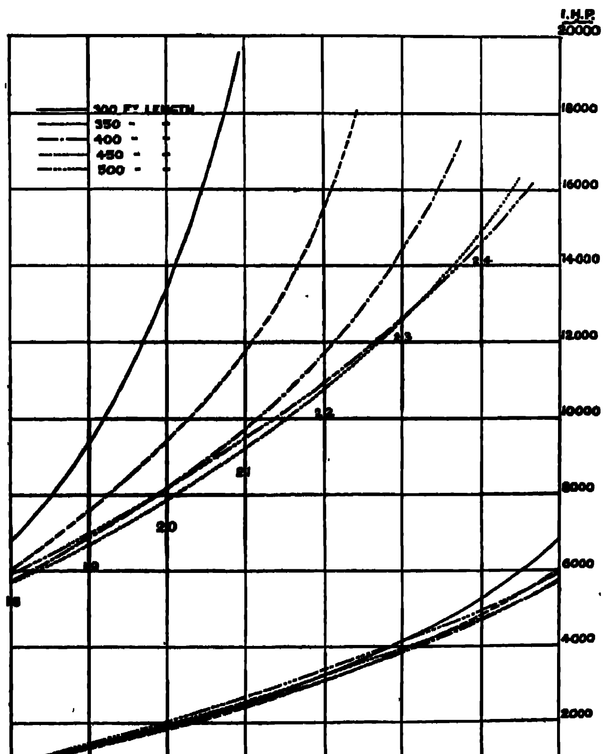

FIG. 4.—Curves of I.H.P. for a vessel of 5000 tons displacement.

and revolutions of the propeller. Mr Froude resolved this into its elements, namely: (1) useful thrust or ship's true resistance; (2) augmentation of resistance due to the action of the propeller (since called thrust deduction); (3) edgewise friction of propeller blades; (4) initial friction; (5) working friction; (6) air-pump and feed-pump duty. The results obtained from this analysis are of extreme interest as indicating the various sources of loss between

the actual I.H.P. and the H.P. due to the ship's net resistance (called Effective Horse-Power), but in the light of more recent experiments the values arrived at have been somewhat modified.

For estimating the indicated horse-power required to give a particular speed to a steamer there are two distinct courses open, according to the information available. One is the use of data obtained from tank experiments, the other the use of data obtained from actual ships. It is sometimes erroneously thought that the former of these courses excludes the latter; so far from this being the case, a good deal of the experimental work of a tank is directed to obtaining as full a knowledge as possible of the inconstancy affecting all comparative speed-results. Models are tried under conditions exactly similar to those of the ships they represent, the speeds and powers of which are known; from the models the effective horse-powers are deduced, and these are compared with the actual powers, the ratio of the former to the latter expressing what is known as the *propulsive coefficient*. In estimating for a new ship the designer has the propulsive coefficients of similar ships before him, together with such knowledge as is available of the cause of their want of constancy. Besides propulsive coefficients, other tank data are kept

Indicated horse-power.

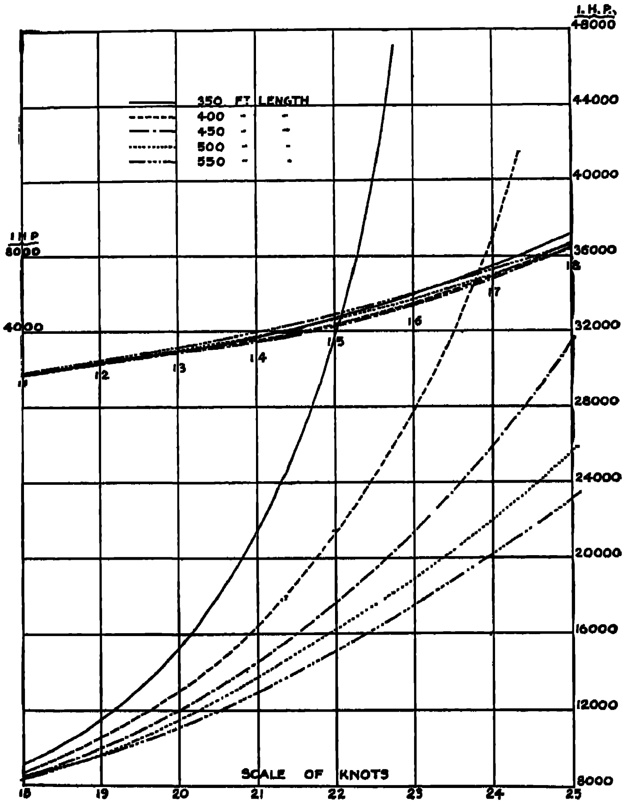

FIG. 5.—Curves of I.H.P. for a vessel of 9000 tons displacement.

in shape for ready application. From such particulars the curve of H.P. for the ship contemplated can be estimated.

With further reference to the propulsive coefficient, a very roughly approximate figure is 0·5; the difference between unity and this coefficient must be regarded as the combined loss of efficiency of all the different parts of the propulsive machinery, including the propeller. As already mentioned, these losses were analysed by Mr W. Froude in 1876 in his paper on the *Merkara*. The loss due to the propeller has since received great attention at the hands of Mr R. E. Froude, but there would seem to be room for more investigation and experiment regarding this and other losses.

The method of estimating speed and power which is probably most commonly used is one involving a relation between I.H.P., displacement, and speed, expressed by the formula—

$$\frac{(\text{Speed})^3 \times (\text{Displacement})^{2/3}}{\text{I.H.P.}} = C,$$

C being called the *Admiralty coefficient*. The value of C varies considerably for different speeds even of the same ship. For it to be constant, the I.H.P. would have to vary as the cube of the speed; if resistance varied as the square of the speed and I.H.P. as resistance and speed, the condition of constancy would be fulfilled. Resistance-variation, however, is not so simple. Again, in the dependence of I.H.P. on resistance and speed important terms are involved causing considerable variations. Those who use the Admiralty coefficient for estimating are very careful to choose their data from practice with which they are well acquainted, and to see that they do not press the application beyond the limits

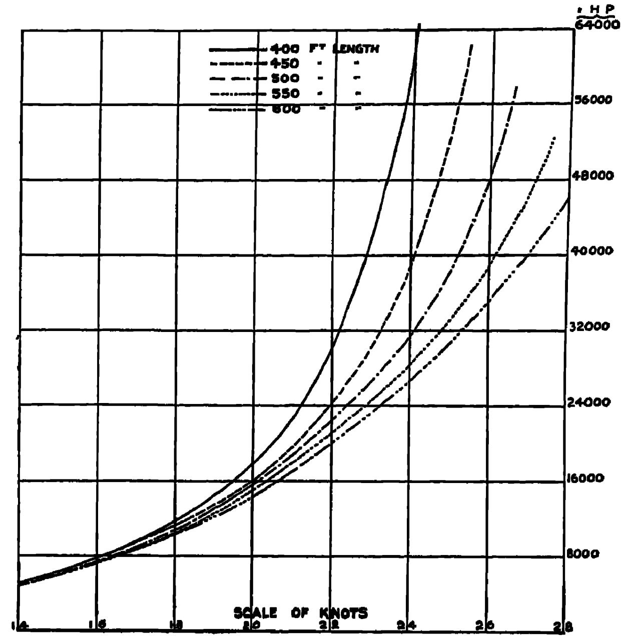

FIG. 6.—Curves of I.H.P. for a vessel of 14,000 tons displacement.

that the circumstances justify. In some cases great care is taken that the speed for the ship under estimate is the corresponding speed of the ship estimated from, or that the departure from the corresponding speed is not great. (Corresponding speeds are those varying as the square root of the lengths. These are the speeds

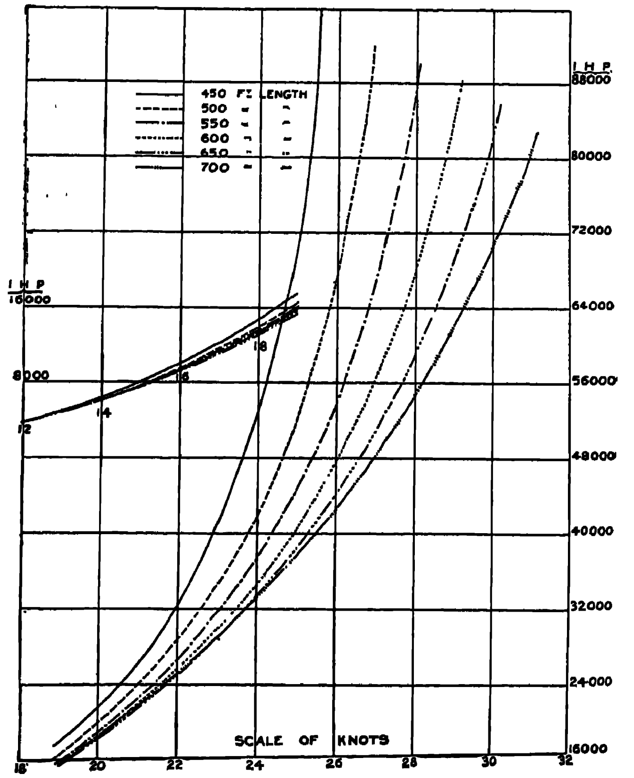

FIG. 7.—Curves of I.H.P. for a vessel of 20,000 tons displacement.

used in the law of comparison.) Again, between the ship under estimate and the ship estimated from, a general similarity as to form and as to proportions of length, breadth, and draught is sought.

A general indication only can here be given of the value of the

coefficient C. For good results it may be said to vary from 200 to 300 (speed in knots, displacement in tons), but many instances will be found of values both above and below this range; in steam launches (to take only one instance), where the speed is high in relation to the square root of the length, it may be as low as 80.

Use of law of comparison. As an illustration of the use of the law of comparison in estimating I.H.P. from the performance of a similar ship, the following example is given:—A vessel 300 feet long, $36\frac{1}{2}$ feet broad, $13\frac{1}{2}$ feet draught, and 2135 tons displacement requires 7000 I.H.P. for a speed of 20 knots. It is required to estimate the I.H.P. of a similar ship of 3000 tons displacement at the corresponding speed. The ratio of displacements being 3000/2135, the ratio of linear dimensions will be the cube root of this, or 1·12, and the ratio of corresponding speeds, the sixth root, or 1·06. The dimensions of the 3000-ton ship will therefore be 336 feet × 41 feet × 15·1 feet, and the corresponding speed 21·2 knots. At this speed the I.H.P. of the 3000-ton ship will be according to the law of comparison, $7000\times\left(\frac{3000}{2135}\right)^{7/6}=10{,}400$ I.H.P. about. Thus for a vessel similar to the above, 336 feet × 41 feet × 15·1 feet, with a displacement of 3000 tons, 10,400 I.H.P. is required for a speed of 21·2 knots. In this use of the law of comparison we make several assumptions:—(1) The machinery and propellers will work with the same efficiency in both cases; (2) the surfaces of the two vessels are in the same condition; and (3) the correction for surface friction in passing from one ship to the other of different length is unnecessary. (This correction is of great importance when passing from a model to a full-sized ship.)

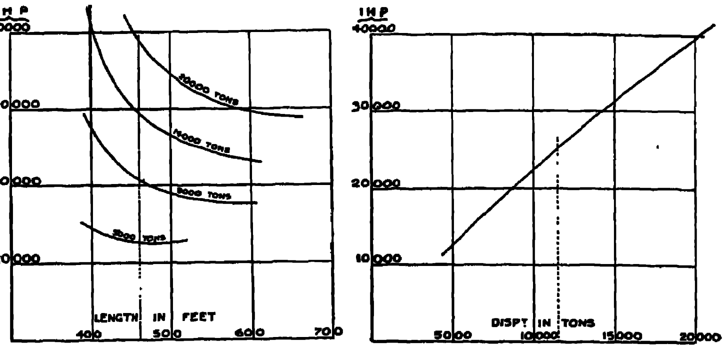
Power and speed. To illustrate what has gone before, and at the same time to afford useful data for estimating the I.H.P. of vessels of a particular type, a number of diagrams have been constructed (Figs. 3–7) showing for each of five displacements a series of curves of I.H.P. plotted to a base of speed for ships of various lengths. They are based on the steam-trial results of the Elswick cruisers and other data. The volume of displacement of the above vessels is approximately one-half that of the circumscribing parallelopipedon, or in other words the "coefficient of fineness" is about 50 per cent.—a very fair average value for modern cruisers. These results will only hold for vessels of about the same coefficient of fineness, for experience with models has shown this coefficient to have an important bearing on resistance. With this restriction the series of curves enables an approximate estimate to be made, by a process of interpolation, of the I.H.P. necessary to drive at any required speed a ship of given dimensions within a wide range of displacement and length. It must be borne in mind, however, that there are many possible features in the form of a vessel which militate against a good performance, principal among which we may mention the following:—sudden change of curvature in the curve of sectional areas, parallel middle body, too full a water-line, unduly large ratio of beam to draught; and to realize so good a performance as is represented by these curves we must suppose the lines of the ship designed to avoid, as far as possible, any of these features. Besides this, the engines and propellers must have been designed to minimize the waste of power in engine friction, churning of the water by the propellers, &c.; the ship must have a clean bottom, and be run in deep water under favourable conditions of wind and sea.

As a numerical example of the use of these curves, suppose we wish to estimate the I.H.P. necessary to drive a cruiser of 10,500 tons displacement and 460 feet length at a speed of 23 knots. We first plot a series of cross curves of I.H.P. on a base of length of ship (see Fig. 8) for each of the five displacements. By cutting this series at 460 feet length we again plot a cross curve of I.H.P. (Fig. 9), this time on a base of displacement. Lastly, we cut this curve at 10,500 tons displacement, which gives us 23,500 as the I.H.P. required. By repeating this process for a series of speeds, a complete curve of I.H.P. could be constructed.

The curves bring out very strikingly the great importance of giving a ship sufficient length if she is to run at high speeds. Take, for example, the curves on Fig. 3 for ships of 2000 tons displacement. The 350-feet ship here requires 2100 I.H.P. for 16 knots and 4200 for 20 knots, *i.e.*, the I.H.P. is doubled in passing from 16 to 20 knots. But $2=\left(\frac{20}{16}\right)^3$ approximately, indicating that for this ship the I.H.P. varies as the cube of the speed within these limits of speed, and therefore the resistance varies as the square of the speed. On the other hand, as the speed of the 200-feet ship passes from 16 to 17 knots the I.H.P. increases from 3800 to 8200, or approximately in the ratio 2·2. But $2{\cdot}2=\left(\frac{17}{16}\right)^{13}$ approximately, indicating that the resistance is actually varying as the 12th power of the speed for this ship between 16 and 17 knots. Practically so short a ship of this form could not be driven at a greater speed than 17 knots, for after this speed is reached any moderate increase of I.H.P. would not sensibly affect the speed.

This excessive rate of growth of I.H.P. does not continue indefinitely, for after a certain speed is reached the rate suddenly begins to fall off, and eventually will again bear a reasonable relation to the rate of growth of the speed. The phenomenon is a result of the harmonic nature of the wave system, and is not confined to abnormally short ships. In fact, it is most apparent in small fine vessels run through a wide range of speed, such as torpedo-boats and destroyers. Fig. 10 shows, for such a vessel, three curves plotted to a base of speed, the ordinates being respectively—I.H.P., $\frac{\text{I.H.P.}}{(\text{speed})}$, $\frac{\text{I.H.P.}}{(\text{speed})^3}$. The second of these is of course a curve of resistance, and the rapid rise and fall of the rate of growth of resistance manifests itself in this resistance-curve by a very marked hump between 15 and 25 knots speeds. The third curve, that of $\frac{\text{I.H.P.}}{(\text{speed})^3}$, is interesting as affording, by its slope at different points, a very good indication of this rate of growth.

Up to 13 knots speed this curve is not far from being horizontal, indicating that till then the resistance is varying about as the square of the speed. The rate of growth increases from this point till it reaches a maximum at 15 knots, and then falls off till at 19 knots the resistance once more varies as the square of the speed. From this point onward the resistance increases approximately according to the above law. It may be noted that



FIGS. 8 and 9.—Cross curves for determining the I.H.P. of a vessel of 460 feet length, 10,500 tons displacement, and 23 knots speed.

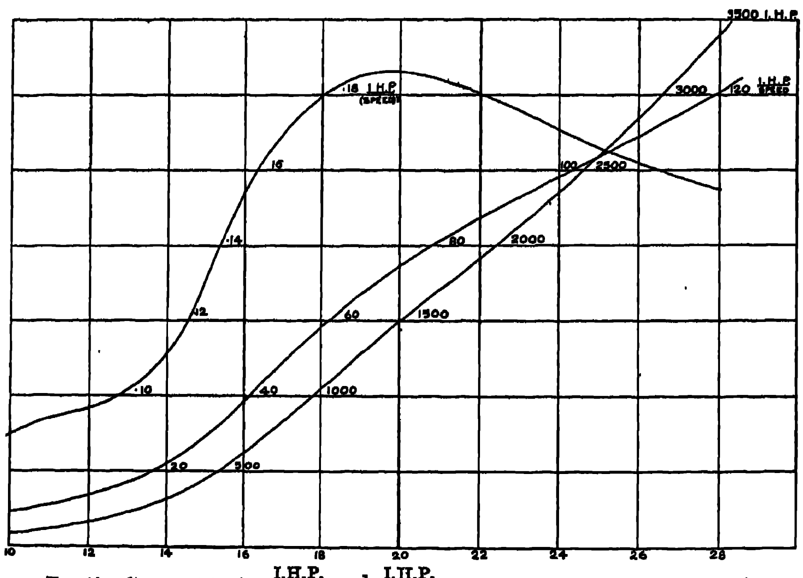


FIG. 10.—Curves of I.H.P., $\frac{\text{I.H.P.}}{(\text{speed})}$, and $\frac{\text{I.H.P.}}{(\text{speed})^3}$ for a vessel of 120 tons displacement.

at 19 knots the ship's statical wave has approximately the same length as the wave which would travel freely at the same speed as the ship, and this determines the position of the maximum value of $\frac{\text{I.H.P.}}{(\text{speed})^3}$. In this connexion a fact pointed out by Professor Biles in a paper read before the Institution of Naval Architects in 1881 is interesting. When the resistance of a form varies as the 6th power of the speed, an increase in the displacement by a proportionate enlargement of dimension will not cause an increase in the resistance for the same speed; and when the resistance varies as a higher power of the speed than the 6th, the resistance will actually be reduced by increasing the displacement.

As the speed is decreased, the advantage of the longer ship rapidly falls off, and at low speeds the longer ship actually requires more I.H.P. to drive it than the shorter one of the same displacement. For example, if we compare 5000-ton ships of 400 and 450 feet lengths (see Fig. 4) at 23 knots, the 400-feet ship requires 1800 more I.H.P. than the 450 feet, but at 17½ knots the I.H.P.'s required are almost equal (shown by the curves crossing); and if the speed is further reduced, the 450-feet ship becomes the worse of the two. The reason of this is not difficult to see. At high speeds the resistance is chiefly caused by surface disturbance or wave-making, and this is less in a fine long ship; but at low speeds the resistance consists almost entirely of surface friction, and consequently is proportional to the wetted surface of the ship. Now lengthening a ship of fixed displacement, with corresponding reduction of beam and draught, increases the wetted surface, just as increasing the eccentricity of an ellipse of fixed area increases the perimeter. Consequently the longer ship has the greater surface-friction resistance. In fact, for a given displacement and speed we can find a definite length of ship which will require the minimum expenditure of I.H.P., but structural and other reasons would generally make this length too great for practical purposes. This "best length" will, of course, increase both with speed and displacement. As a result of this reasoning we should expect the order of the curves at low speeds to be the reverse of that at high speeds on each sheet, *i.e.*, the ordinate for the longest ship should be highest instead of lowest, and so with the others. This would have been more apparent had the curves been plotted on a more open scale and continued to a lower speed than has been found convenient to do.

Before proceeding to discuss screw propellers, it will be desirable to define some of the terms employed. The product of revolutions and pitch is often called the speed of the propeller; it represents what the speed would be in the absence of slip. Speed of advance, on the other hand, is applied to the movement of the propeller in the line of its action without relation to its rotation. The difference between speed of propeller and speed of advance is the *slip*. Slip is often spoken of as either "apparent" or "real": if it is "apparent" for speed of advance is taken the speed of the ship, when it is not real, simply because it takes no account of the "wake" water carried with the ship. For analytical purposes this wake must be taken account of, and the speed of advance measured with respect to it; the resulting slip deduced is then the "real" slip. Since the wake moves with the ship, the speed of advance of propeller through the wake is, speaking generally, less than the speed of the ship, and the real slip is greater than the apparent slip. "Velocity of feed" is the term employed by Mr Barnaby for the speed of advance through the wake, and in some respects it expresses what is wanted better than any other term.

Screw propellers.

Previous to 1878 investigations into the action of the screw propeller were made on the following lines:—The velocity of water flowing past a propeller blade was resolved (1) normally and (2) tangentially to the blade; further, the normal velocity was resolved into (*a*) longitudinal and (*b*) rotational velocity. A fundamental error underlying this double resolution was that it did not correctly measure the forces involved, or take account of the effect of the obliquity of a plane moving at an angle to itself through the water. In Mr W. Froude's 1878 paper "on the elementary relation between pitch-slip and propulsive efficiency" this error was corrected. On the authority of Lord Rayleigh's investigations, supported by experiment, it was shown that the normal pressure acting on the face of a plane relatively narrow in the line of motion depends upon the sine of the angle of inclination rather than on the square of the sine, as had been previously assumed. Starting with this fact as a basis, and using figures for normal pressure and for surface friction obtained from his own experiments, Mr W. Froude constructed mathematical expressions for the forces acting on a plane area moving obliquely through the water at a given speed. Treating this plane area as an elementary portion of a propeller blade, and considering the forces in relation to resolved speeds, he obtained further expressions for (*a*) effective work done by the plane in the direction corresponding to the line of motion of the ship, and (*b*) total work required to be done in the circumferential direction to maintain the motion. The ratio of (*a*) to (*b*) in any case represented the efficiency for that case. He was led to the following conclusions regarding maximum efficiency:—(1) The slip angle (obliquity of surface to the line of its motion) ought always to have the same value (proportional to the square root of the coefficient of friction); and (2) when this is so, the pitch angle should be 45°. The maximum efficiency obtained from this investigation was 77 per cent. This theoretical investigation, though of importance and interest, does not exactly represent the actual conditions, inasmuch as the deductions from a small element are applied to the whole blade, and, further, the considerable disturbance of the water when a blade reaches it, owing to the passage of the preceding blade, is ignored.

The experiments on screw propellers which Mr W. Froude was carrying out in 1878 at the Torquay tank, and the nature of which he had in the previous year described in a paper read before the Institution of Civil Engineers, were after his death continued by Mr R. E. Froude, and some of the results were communicated to the I.N.A. in 1883, 1886, and 1892. A partial series on somewhat the same lines was also described by Mr Thornycroft to the I.N.A. in 1883. In the Torquay experiments four four-bladed propellers were used, with a uniform diameter of 0·68 feet, and having relation of pitch to diameter, or pitch-ratio, of 1·225, 1·4, 1·8, and 2·2 respectively. The pitch of each blade was uniform and the shape elliptical. The width in the middle of the developed blade was $0{\cdot}4 \times \frac{\text{diameter}}{2}$, so that the developed surface (making no deduction for the area of boss) was 0·4 × disc area. In the experiments a uniform speed of 206 feet per minute was obtained throughout; for the most part the propellers were tried in the open, no ship model being represented in connexion with them. In each case, while the speed of advance was uniform, the number of revolutions was varied throughout a sufficient range of experiments, the slip or slip-ratio was thus varied, by slip-ratio being meant $1 - \frac{\text{Speed of advance}}{\text{Pitch} \times \text{revolutions}}$. The thrust and also the turning couple were ascertained in each experiment, the relation of work done by thrust to work of turning moment expressing the efficiency. In combining the results from the four propellers great assistance was derived from the discovery that the curves expressing the variation of efficiency with slip-ratio had a close similarity, one curve being practically producible from another by an alteration of the scale used for the abscissæ of the curves, namely, the slip-ratio. Making the alteration in each case, a diagram was obtained in which one efficiency curve did duty for all the propellers. The ordinates of this curve represented efficiencies, the abscissæ represented slip-ratios, varying uniformly for any one propeller, but requiring a different scale of interpretation for each propeller in question according to its pitch-ratio. The data given by this diagram, although derived from propellers with four pitch-ratios only, were readily made applicable, by interpolation, to any other pitch ratios within the limits of those actually experimented upon. For practical application the next step needed was to make the results obtained from propellers of one diameter, moving at one speed of advance, available for any speed and any size. For this purpose the following assumptions were made, which, however, are well supported by experimental results:—(1) With given slip-ratio the thrust of a given screw varies as the square of the speed of advance. (2) With given slip-ratio and given speed of advance and given design of screw, with varying size, the thrust varies as the square of the dimensions. (3) With given slip-ratio and given design of screw the efficiency is unaffected by variations of speed or size of screw. The data from the small propellers were interpreted in accordance with the above by the introduction of the necessary multipliers and divisors into the scales of the diagram already referred to. This diagram is capable of very considerable modification, in accordance with the class of problem to the solution of which it is to be applied. Suppose it is desired to ascertain the best propeller for a certain speed of a given ship. Mr Froude assumes the effective horse-power to be known. There are then still four variables to be dealt with, namely, the diameter, the pitch or pitch-ratio, the revolutions, and the efficiency. If the revolutions, as is usually the case, are practically fixed by the size of the engines available and the horse-power to be developed, one other unknown is supplied, and Mr Froude's working diagrams (see *Trans. Inst. Nav. Arch.*, 1892) then give the means of expressing diameter in terms of efficiency and pitch-ratio, these last two variables being mutually involved. In ultimately deciding upon the diameter there is the question of space to be considered; and also, in fixing the pitch-ratio, a less efficiency than the maximum has often to be accepted, in order to avoid adopting a pitch-ratio either larger or smaller than seems justified by actual experience.

The results so far described were obtained from four-bladed propellers of the size already given. Some supplementary experiments were made upon other propellers having three blades and two blades. Other things being approximately the same, these gave thrusts differing from the thrusts of the four-bladed propellers in the ratios 0·865 to 1·0 and 0·65 to 1·0 respectively. The data for four-bladed propellers can therefore, with some qualification, be used

for the others, providing the thrusts, and consequently horse-powers, are reduced in the above ratios. A propeller with wider or narrower blades than used in these experiments would also require some corresponding modification of the thrust or horse-power readings of the data.

As already mentioned, the results just dealt with were obtained from propellers having no ship model in connexion with them. The effect of the presence of a ship model upon the screw has, however, received very careful attention, as has also the correlative effect of the screw upon the resistance of a ship model behind which it is working. The former is the effect of the wake, whereby the speed of advance of the propeller through the water is less than the speed of the ship. The latter is an enhancement of resistance due to the suction caused by the propeller, so that the thrust required to propel the model is greater than the net resistance; this difference is generally spoken of as "thrust deduction." Mr Froude in his curves assumes certain standard values for water and thrust deduction; the actual wake, expressed as a ratio of the speed of advance, is given by him for a number of ships, and a method of correction is pointed out for cases where the wake is known to be other than the normal.

Cavitation. The phenomenon of cavitation in connexion with the action of a propeller was encountered in a practical form in 1894. Experiments on the torpedo-boat destroyer *Daring*, made by Mr Barnaby in 1894, showed that in this vessel when the total thrust of the screw, divided by its projected blade area, amounted to 11¼ lb per square inch, a sudden change took place in the slip-curve, the slip being abnormally increased. The reason for the change was traced to the inability of the water at the back of the blade to follow the blade's motion, a partial rupture of the column of water occurring, and cavities forming in consequence. A thrust of 11·2 lb means approximately 5·6 lb push on the water leaving the screw-face and 5·6 lb drag on the water approaching the screw-back. The discrepancy between 15 lb and 5·6 lb shows "that rupture occurs at parts of the screw surface long before the mean thrust per square inch of the whole surface reaches the amount due to the external air-pressure."

Process of Design.

When a shipbuilder is approached for the production of a new ship, he must be informed of the requirements of the case; the kind of trade or service in which the vessel will be engaged; her speed; if she is to be a steam vessel, the distance she must run on ordinary voyages without re-coaling; the weight of cargo to be taken, or the number of passengers to be carried, and the kind of accommodation required for them. Very frequently these requirements will include certain limits of size, draught, cost, or tonnage, which must not be exceeded. In addition, it must be stated in what society, if any, she is to be classed, as this will determine the details of the scantlings to be employed. The shipbuilder will usually have, to guide him, the details of some successful ship or ships previously built to fulfil the same or similar conditions as in the vessel required, and he will probably know what measure of success or popularity the respective features of the vessel or vessels have earned on service. The dimensions can in this case be at once fixed to provide the necessary speed, strength, stability, and seaworthiness, and the cost of the vessel determined. If the departures from some similar ship of known and approved qualities are small, the details of the new ship can be inferred directly from those of the similar ship, and modified drawings, specifications, &c., can be rapidly prepared, and the building proceeded with. On the other hand, the departures from previous vessels or the usual practice may be very great, in which case much will depend on the shipbuilder's skill and judgment. Considerable investigation and calculation may be required to ascertain how the desired qualities and conditions can be best provided for. Outline drawings are first prepared to the dimensions which may be considered suitable, and the calculations are made on this assumed design. These will include estimate of the weights of the hull, of the machinery, equipment, &c.; and if it is not intended to class the vessel in some registration or classification society, questions of strength will have to be considered. If, however, the vessel is to be so classed, the determination of the structural strength may be omitted, as the scantlings required by the rules of such society are arranged to provide sufficient strength. If the calculations show that the dimensions assumed do not enable the required conditions to be fulfilled, the dimensions must be modified in the direction indicated by the calculations, and the calculations made over again. This process must be continued until a satisfactory result is obtained. As soon as the dimensions obtained for the vessel are found to be appropriate, more complete drawings are put in hand, and the final calculations pertaining to the displacement sheet, weights of hull and equipment, centre of gravity and trim, metacentric diagram and curves of stability and speed, are made.

There are many variations in the division of the work of designing and building a ship. In building large passenger ships the design often originates with the owner's or steamship company's staff, and in some cases naval architects are employed, completed drawings and specifications being handed over to the shipbuilder with the order for the vessel. In other cases shipbuilders work in close connexion with the steamship companies, and the business relations are of a very simple character, the company being content simply to send an order, with a note of the principal dimensions and type of ship required, leaving the determination of all details of the design in the hands of the builders. The general practice lies between these two extremes. In any case, complete design drawings and detailed specifications are necessary for the shipyard operations, and if not supplied must be prepared by the shipyard staff. Sometimes outline drawings of the vessel on a small scale—including an elevation or side view, one or two plans of the main deck and other parts, and a short description of the vessel—are first prepared, and are called an outline or sketch design; but usually the information which constitutes a design comprises a sheer plan, profile and plans of each deck on a ¼-inch scale, a midship section on a ½-inch scale, and a complete specification.

The sheer drawing gives the outside form of the ship. It consists of an *elevation* showing her longitudinal contour; the positions of the decks; the water-line or line at which she will float, and certain other lines parallel to this and equally spaced below it, which are also called water-lines; a series of vertical lines equally spaced from stem to stern, called "square stations"; and certain other details: of a *body plan* showing the sectional form of the ship at the square stations, supposing her to be cut by transverse planes at these stations: and of a *half-breadth plan* showing the form of the ship at the several water-lines, supposing her to be cut by horizontal planes at the levels of these lines. The profile and plans give all the internal arrangements of the vessel, the holds or spaces set apart for cargo, the passenger accommodation, the positions of the engines and boilers, the accommodation provided for the crew, and other principal fittings. In a warship there are no cargo holds or passenger accommodation, but the distribution of the armament and magazines, the armour, and other arrangements for the protection of the vessel against injury in action are carefully shown, and the appropriation of every portion of the internal capacity of the vessel is clearly indicated. The *midship section* shows the structural arrangements of the vessel, and usually the scantlings of the most important parts. The *specification* is a statement of all the particulars of the vessel, including what is shown on the drawings as well as what cannot be shown on them; the quality of the materials to be used is described, and the scantlings of the same carefully recorded; and it is clearly stated

how parts not manufactured by the shipbuilders are to be obtained.

Registration societies. As already intimated, the register societies, the object of which is to class ships with regard to their strength, durability, and general seaworthiness, mainly for purposes of insurance, fix the quality and strength of the material used, the scantlings of all the parts, and other details for ships built under their rules. But they also record all the important features of the ships so classed, and thus provide most of the information which the shipbuilder requires for the design and construction of ordinary vessels. In fact, the design for such ships, if design it can be called, consists in choosing from a large number of examples, differing very little from one another and all known to be good seagoing vessels, the exact dimensions and type of ship which the price named will admit of, and preparing outline drawings of the internal arrangements accordingly.

The principal registration and classification societies in operation in 1901, and the number of vessels (sailing and steam) classed at each, were as follows:—

Lloyds Register of British and Foreign Shipping, having its headquarters in London .	9290 vessels.
British Corporation for the Survey and Register of Shipping, in Glasgow	477 ,,
Bureau Veritas International Register of Shipping, at Paris	5122 ,,
Norske Veritas, at Christiania	2076 ,,
Germanischer Lloyd, at Berlin	1954 ,,
Record of American and Foreign Shipping, at New York	1530 ,,
Registro Italiano	1116 ,,
Veritas Austro-Ungarico	1107 ,,

Of these societies, *Lloyds Register*, as at present constituted, has existed since 1834; at that date it superseded two rival institutions having a similar object. The name Lloyds is traced back to Lloyds' Coffee-house, once situated in Lombard Street, in which underwriters met for business purposes, and from which in 1696 they issued their first publication. The first printed register was issued about 1726, a copy dated 1764 being still extant. The office of surveyors is referred to in a register book of the date 1781, but there are evidences that in 1768 repairs were superintended by officers of the society. In 1799 surveyors were stationed at twenty-four ports in the United Kingdom. In 1822 the register for the first time recorded a steamship. In 1824 appeared the first "Instructions to Surveyors" as to the carrying out the rules for classification; and in 1834, on the establishment of the present society, precise regulations were issued regarding the survey of steamers. An iron ship was built under survey and received a class in 1837, while the first rules for the construction of iron ships were issued in 1855. In 1851 a composite vessel was classed, but it was not until 1867 that rules for the construction of such vessels were issued. Steel was accepted in 1867, experimentally, steel being then made by the Bessemer process. Steel by the Siemens-Martin process was first used for two small steamers in 1877. Engineer surveyors were first appointed in 1874. The society is maintained by the shipping community; its affairs are managed by a committee of fifty-eight members — merchants, shipowners, and underwriters—elected to represent the important shipping centres of the country, and there are branch committees at Liverpool and Glasgow. The society has a staff of 170 ship and engineer surveyors in the United Kingdom, and 114 at the principal foreign ports.

In the case of a new vessel intended for classification, the plans for its construction are in the first place submitted to and approved by the committee; the building proceeds under the supervision of the local surveyor, and when completed, a *character* is assigned to the vessel by the committee upon that surveyor's report. The society issues annually to its subscribers a register containing particulars of the classification of vessels to which characters have been assigned, together with many other details. All other merchant vessels of the world, of 100 tons and upwards, except wood vessels on the Great Lakes of North America, are included in the work. This register contains particulars of the age, build, tonnage, dimensions, and ownership of some 28,000 vessels.

The *Bureau Veritas* was founded in Antwerp in 1828, one of its principal aims being to make known to underwriters the qualities and defects of ships frequenting Dutch and Belgian ports. In 1832 the headquarters were moved to Paris, and in due time its influence spread to all countries where shipowning or shipbuilding existed; it is now represented in over 200 districts comprising 1500 ports. In 1851 rules were drawn up for the construction of wood ships, and about 1867 for iron. Rules for steel came later, and also rules for the construction of machinery. A staff of surveyors formed part of the organization from the beginning; and in the earlier days the professional experience of the surveyors was the only guide as to what was necessary and sufficient. With the lapse of time, and with increased variety of construction and complication of interests, something more than individual judgment and experience became necessary, and with the Bureau Veritas, as with Lloyds and other similar societies, definite rules were introduced, and by their means a greater uniformity of practice was attempted and secured.

The *British Corporation* was founded in 1890, and obtained its charter under the Merchant Shipping Acts for the assignment of freeboards; its first rules were issued in 1893. Its inception was due to the enterprise and influence of a number of leading shipowners, shipbuilders, and engineers throughout the country, and more particularly in Glasgow and the West of Scotland, the first aim of the founders being to provide an independent society, thoroughly capable of dealing with the complicated questions which were likely to arise under the Load Line Act then coming into operation. The Liverpool Registry, which had once been independent, had been absorbed into Lloyds some years before, and it was felt that the enormous shipbuilding interests of the country demanded the existence of a society whose friendly rivalry with the great society of Lloyds would have a beneficial influence on the shipbuilding of the country.

The *Norske Veritas* was established in 1864 by the various marine insurance clubs of Norway. Previously each club had its own separate staff of surveyors, on whose report to their club depended the class of the vessel and the premium to be paid. As ships rose in value and reinsurance became the rule, something had to be done for mutual protection. By the establishment of the *Norske Veritas* one uniform system of classing and valuing was substituted for the older methods. In the matter of rules this society kept pace with the changes of the mercantile marine; it provided, as the occasion required, for the introduction of iron and steel in place of wood, and of steam in place of sails.

The *Germanischer Lloyd* was established in 1867, and reorganized as a joint-stock company in 1889. Its functions are carried out by officers at the central office in Berlin, assisted by a staff of 49 ship and engine surveyors in Germany and 138 at the principal foreign ports, the latter under control of agents, who are mostly consuls.

The *Record of American and Foreign Shipping* was established in 1867 by the American Shipmasters' Association (now called the *American Bureau of Shipping*), and is the standard American authority. Its rules for the construction and classification of vessels, as published in 1889 and amended in 1900, received the approval of the U.S. Navy Department and of the several boards of American underwriters. It has agents and surveyors in all the principal ports of the world.

The present rules of the above societies apply in every case to construction in steel and iron, and in most cases to construction in wood also. The tables accompanying the rules for steel and iron are in some cases quite distinct; in others they are so arranged that steel or iron scantlings may be read off the same tables, interpreted, when the material is steel, to give some 20 per cent. less sectional area than when it is iron. The Bureau Veritas and Germanischer Lloyd make a further distinction of materials by discriminating between common iron and superior iron.

The highest class assigned, upon the completion of a ship by the societies referred to, is as follows:—

Lloyds	✠	100A	1	✠ L.M.C.
Bureau Veritas . . .	⓵	3/3L	1 1	✚
British Corporation . .		B.S.✻	M.B.S.✻	
Norske Veritas . . .		A1	1	M. & K.V.
Germanischer Lloyd . .	✚	100	A_4.L.	
Record of Amer. Shipping	✚	A1	M.C.	

The star or cross in each case denotes special survey. In *Lloyds* 100A refers to conformity of scantlings with the tables; the figure 1, to the efficient state of the equipment, including anchors and cables; L.M.C. denotes Lloyds Machinery Certificate. In the *Bureau Veritas* the large 1 expresses first division of classification (out of three); the two rings around the 1 denote that the ship is divided into a sufficient number of water-tight compartments to enable her to float in still water with any two of them in free communication with the sea. Very few ships in the register have the double ring, but some have a single ring ①, denoting power to float in still water with any one compartment in free communication with the sea; 3/3 expresses completeness and efficiency of hull and machinery; the first 1, that the wood portions of the hull are entirely satisfactory; while the second 1 has the same significance in respect to the equipment of masts, spars, rigging, anchors, chains, and boats. In the *British Corporation Register*, B.S. signifies conformity with all requirements, these letters standing for British Standard; M.B.S. signifies that the machinery also conforms. In the *Norske Veritas*, A1 refers to quality and scantlings, mode of construction, and state of preservation; the second 1, to thickness of shell-plating; M. & K.V., to efficiency of engines and boilers.

The tests for steel material to be used in building the ships, as required by the same societies, may be tabulated as follows :—

	Ultimate Tensile Strength.	Elongation on Length of 8 Inches	Temper Test.
Lloyds . . .	Bet. 28 and 32 tons per sq. in.	Not less than 20 per cent.	Sample heated to a low cherry red and cooled in water at 82° F.
Bureau Veritas .	Bet. 27 and 32 tons per sq. in.	,,	
Brit. Corporation .	Bet. 28 and 32 tons per sq. in.	,,	
Norske Veritas .	Bet. 28 and 32 tons per sq. in.	,,	
Germanischer Lloyd	Bet. 26 and 31 tons per sq. in.	,,	None required.
Record of Amer., &c., Shipping	Bet. 58,000 and 68,000 ℔ per sq. in.	,,	Same as above.

For thin plates 16 per cent. elongation is allowed; for garboard strake plates *Lloyds* minimum strength is 26 tons, *British Corporation* 25 tons; for frames and beams (either angles or bulbs), strength may be as high as 33 tons. For rivet steel the *British Corporation* require a tensile strength between 25 and 30 tons per square inch, with elongation of 20 per cent. on a length of 8 inches. In view of the two varieties of iron accepted by the *Bureau Veritas*, the superior quality has also to be subjected to tests; the tensile strength of most parts must not be less than 22 tons per square inch with the fibre and 18½ tons across, the elongation on 8 inches, 7 per cent. with the fibre and 4 across; hot and cold bending and forge tests for angle bars are also prescribed.

Board of Trade supervision.

The regulation of certain matters connected with the design of merchant ships falls upon the Marine Department of the Board of Trade. The authority of the Board is the Merchant Shipping Act of 1894, which consolidated previous enactments. These matters include the measurement of tonnage, and provision for the safety and comfort of passengers and crew. The former is discussed in a separate article (see TONNAGE), but it may be mentioned here that the following countries have at various dates accepted the British rules for tonnage: United States, Denmark, Austria-Hungary, Germany, France, Italy, Spain, Sweden, Netherlands, Norway, Greece, Russia, Finland, Hayti, Belgium, and Japan. The amount of deduction for propelling power varies in Spain, Sweden, Netherlands, Greece, Russia, and Belgium, but option is granted to owners to have the engine-room remeasured under the rules of allowance for engine-room relating to British ships. Special certificates are at present also issued, on application, to vessels trading to Italian ports, as the Italian authorities do not at present recognize certain sections of the Act of 1894 in regard to deductions from tonnage and exemptions from measurement. Special tonnage certificates are also issued for the Suez Canal, where the measurements of ships and deductions from tonnage vary from British rules, and are detailed at length by the Board of Trade in their Instructions to Surveyors.

With regard to safety and comfort, the surveyors have to see, among other matters, that the crews are properly accommodated, and the passengers not too crowded; that the boats and life-saving appliances are sufficient; that the lights and signals are in order; that the freeboard is sufficient and ship otherwise seaworthy; that grain cargoes are properly stowed; and that coal cargoes are adequately ventilated. Any question of doubt as to the strength of passenger vessels has to be referred to the Board of Trade, and in future midship sections, with all particulars marked thereon, are to be submitted in the case of all new steamships building under survey for which passenger certificates are required. A passenger certificate is required whenever a steamer carries more than twelve passengers. In granting it, the Board of Trade recognizes five different services, ranging from foreign-going steamers to excursion steamers in smooth water. The Board of Trade rules for scantlings are not published officially.

Load line and freeboard.

A Bill, introduced into Parliament in 1869, dealing with the load line question, contained a clause requiring the draught of water to be recorded at which a vessel is floating when leaving port. This Bill did not pass; but in the following year the Merchant Shipping Code Bill was brought in, containing the same provision, and, in addition, requiring a scale showing the draught of water to be marked on stem and stern post of every British ship. This became law in 1871. The same Act empowered the Board of Trade to record the draught of water of all sea-going ships on leaving port by surveyors duly authorized. In March 1873 a Royal Commission on "Unseaworthy Ships" was appointed by the British Government, and one of the questions considered was that of the load line. In the final report in 1874 the conclusion was arrived at that a settlement of a load line should, in the main, be guided by reserve buoyancy as a first consideration. The Commissioners were, however, of opinion that an Act of Parliament, framed to enforce any scale of freeboard, would be mischievous, if not impossible, as would be any universal rule for the safe loading of merchant ships.

In 1874, in a paper read before the Institution of Naval Architects by Mr B. Martell, tables of freeboard were suggested from data collected at all the principal ports in the United Kingdom. These tables were based on the principle of reserve buoyancy, and were intended to apply to the loading of the various types of sea-going ships then to be dealt with. As an indication of the form of the vessel, it was suggested that a tonnage coefficient of fineness should be used, in order that the tables proposed might be readily adapted to all sea-going ships, whether at that time at sea or in port. In 1875 a short Act was passed, to remain in force only until October of the following year, which embodied as its chief feature the requirement of what was afterwards universally known as the "Plimsoll mark" (after the late Mr S. Plimsoll, M.P., the prime mover in securing legislation for the prevention of overloading in British ships). All British ships were to have the position of the deck shown on the side of the ship, and every foreign-going British ship was to have a circular disc marked below the deck line, indicating the maximum draught to which it was intended to load. The Act in no way fixed the amount of freeboard; this was left to the shipowner. The provisions of the 1875 Act were confirmed by a more comprehensive Act in 1876, which extended the compulsory marking of the deck line and disc to all British ships, except those under 80 tons engaged in fishing and the coasting trades, also excepting yachts or war vessels. Before this Act was passed, the Board of Trade took action, by appointing a committee to consider the possibility of framing rules for the regulation of freeboard. The committee was to be composed of representatives of the Board of Trade, Lloyds, and the Liverpool Underwriters' Registry. This attempt to establish an authorized scale of freeboard failed. Meanwhile the subject was not lost sight of; the collection of data was continued, investigations were carried out, and six years later (in 1882) the committee of Lloyds Register issued freeboard tables, and undertook to assign freeboard, on the basis of the tables issued, on owners making application for the same. In the course of three years 944 vessels had freeboards thus assigned to them, and in the case of 775 of this number the owners voluntarily accepted the freeboards assigned. In December 1883 the Load Line Committee was appointed by the Board of Trade; and after two years' careful deliberation and investigation, involving much labour, the committee presented its report. This report was accompanied by tables, which agreed closely with those previously issued by Lloyds; and they were accepted by the committee of that society in September 1885. Between 1885 and June 1890 (the latter being the date the Load Line Act was passed) 2850 steam and sailing vessels had freeboards fixed by Lloyds, and of these 2520 were taken from the tables. After the passing of the Act in 1890 appointments to assign freeboards were granted to Lloyds, Bureau Veritas, and the British Corporation.

In 1893 the original tables were modified with respect to some of the ports in the United States on the Atlantic, the sailing from or to which in the winter was to subject the ship to a few inches additional freeboard. In 1898 they were further modified (*a*) to exempt ships over 330 feet in length from the additional freeboard just mentioned, and to limit the additional freeboard in smaller ships; (*b*) to give some concession to turret-deck steamers; and (*c*) in some other minor matters.

Loading of grain and timber.

Ships laden with grain have to comply with rules of the Board of Trade, which provide that for single-decked ships there shall either be provision for feeding the hold, or there shall not be more than three-quarters of the hold occupied by grain in bulk, the remaining one-fourth being occupied by grain or other suitable cargo in bags, bales, or barrels, supported on platforms laid on the grain in bulk. For ships with two decks, grain in bulk in the 'tween decks is for the most part prohibited; but certain grains are allowed, provided there are separate feeders for hold and 'tween decks, or else sufficiently large feeders to the 'tween decks, and the hatches and other openings there made available for feeding the holds. In ships with two decks, longitudinal grain-tight shifting-boards must be fitted where grain is carried either in bags or bulk; these shifting-boards must extend from beam to deck and from beam to keelson, and in the case of bulk grain must also be fitted between the beams and carried up to the very top of the space. The regulations also impose a fine not exceeding five pounds for every hundred cubic feet of wood carried as deck cargo which arrives in a ship, British or foreign, in any port of the United Kingdom between the 31st October and 16th April, provided no unforeseen circumstances, as defined by the Act, intervene. By deck cargo in this section is meant any deals, battens, or other wood goods of any description to a height exceeding 3 feet above the deck.

In 1890 a committee was appointed by the Board of Trade to deal with the spacing and strength of transverse water-tight bulkheads, and to make recommendations. The first matter submitted to this committee related to subdivision which should enable a ship to float in moderate weather with any two compartments in free con-

nexion with the sea. The committee, while recommending the above as a standard for sea-going ships of not less than 425 feet in length, and for cross-Channel steamers irrespective of length, suggested less stringent conditions for sea-going ships of shorter length. There was no suggestion of enforcing such subdivision by law; but as a reward for complying, some concession was to be allowed, under the Life Saving Appliances Act of 1888, as to the boats or life-rafts to be carried. On the presentation of the report the matter was, however, allowed to drop, and the rules of Lloyds and the other classification societies are therefore the only rules with practical influence. The subdivision required by Lloyds for all steamers comprises a bulkhead at each end of the machinery spaces, and a bulkhead at a reasonable distance from each end of the ship, making four in all. In addition, for larger steamers other bulkheads have to be fitted, making the total as follows, namely:—

Transverse water-tight bulkheads.

Length of steamer,	280 feet to	330 feet	.	.	5 bulkheads.
,,	,, 330	,, 400 ,,	.	.	6 ,,
,,	,, 400	,, 470 ,,	.	.	7 ,,
,,	,, 470	,, 540 ,,	.	.	8 ,,
,,	,, 540	,, 600 ,,	.	.	9 ,,

The positions of these additional bulkheads, and the height to which they are to be carried, are clearly stated, and rules are given for their scantlings. These scantlings are suitable for purposes of safety in the event of accident; but it is understood that they have to be considerably increased when the bulkhead is also used to withstand frequently the pressure of oil or of water ballast; a deflection of the plating which would do no harm in an emergency once encountered, would certainly become serious if often repeated in the ordinary service of the ship. The foremost bulkhead of the ship receives the name of *collision* bulkhead, or sometimes *fore-peak* bulkhead; the aftermost, the *after-peak* bulkhead. In sailing ships the collision bulkhead alone requires to be fitted.

Practical.

Practical shipbuilding requires a knowledge of the properties of the materials used in the construction of ships, and of the processes by which they are produced or prepared for use, so that they may be suitably selected for the services for which they are intended; also a knowledge of the methods, means, and machinery by which, after delivery in the shipyard, the materials are brought to the requisite shape, erected in their proper relative positions, connected together, and completed so as to form a structure which shall fulfil the intentions of the design, whether large or small, merchant ship or warship. The varieties of ships are very great, and are constantly changing, and thus new problems continually present themselves to the shipbuilder. There is also an ever-increasing demand for rapid production, which necessitates a rigorous and constant search for simplification of methods of work, for labour-saving and time-saving machinery, for improved means of handling material in the shipyard, and for workshops and factories which will more completely prepare and finish their various products before despatch to the shipyard.

Whatever the size of the ship or the type to which she belongs, the general principles of construction remain very much the same in all cases. The following account applies to steel and iron shipbuilding; for particulars of wood and composite construction the reader is referred to the ninth and previous editions of this Encyclopædia. The exterior parts—the bottom, sides, and decks—supply the strength required for the structure as a whole. The bottom and sides are spoken of as the *shell* or *outside plating*, and are, with the decks, kept to the proper shape by means of frames running across the ship, like the rafters in a roof or the ribs in the body. These are called *transverse frames* or *ribs*, and *beams* where they run under the decks. The parts of the frames at the bottom of the ship, where they are made deep and strong to support her when she is docked or grounded, are known as *floors*, while the spaces between these floors are spoken of as the *bilges*. The transverse frames and floors are held upright in their proper relative positions by other frames which run lengthwise in the ship; one at the middle line being called the *centre keelson*, and others fitted at the sides, *keelsons*, *bilge keelsons*, and *side stringers*. All the fore-and-aft frames, taken together, are spoken of as the longitudinal framing. Where tanks for carrying water ballast are built into the bottom of the ship, the centre keelson is called the *centre girder*, and the keelsons or bilge keelsons, the *side girders*. In large merchant vessels, and in all war vessels, except the smallest classes, an *inner bottom* is provided for increasing the security against injury by grounding, and against ramming and torpedo attack in war vessels, in addition to forming tanks for carrying water, either as ballast or for use in the ship. In such cases the centre keelson is called the *vertical keel*, and the keelsons and girders are called *longitudinals*. When the deep vertical transverse plates forming the floors only extend between the keelsons, girders or longitudinals, and are attached to them by angle bars, the floors are called *intercostal* floors, and the keelsons, girders, and longitudinals are said to be *continuous;* on the other hand, when the keelsons, girders, or longitudinals extend only between the frames and floors, they are called *intercostal* keelsons, girders, and longitudinals, and the frames and floors are said to be *continuous*. In large merchant vessels and war vessels, except the smallest classes, much of the longitudinal framing is continuous; and the transverse framing, for the most part, is *built up* of angle bars upon the outer bottom and under the inner bottom, with short plates, called bracket plates, between them, attached to the longitudinals by short angle bars. Frames built up in this way are called *bracket frames*. In small vessels the transverse frames are usually continuous.

Structural parts.

Besides the transverse and longitudinal framing, there are partitions used for dividing up the internal spaces of the ship, which are called *bulkheads;* they are partial, complete, water-tight or non-water-tight, as the circumstances of the case require. In warships the transverse bulkheads are so numerous, in order to restrict as much as possible the entrance of water from damage in action, that they go a long way towards providing the necessary transverse strength, and the transverse frames are consequently made of thinner materials and fitted at greater distances apart than they otherwise would be. Transverse frames are from 36 to 48 inches apart in large warships, and from 24 to 27 inches in large merchant ships. At the extreme ends of the ship the shell plating on the two sides is attached to forgings or castings, which are known as the *stem* at the fore end, and the *stern frame* or *sternpost* at the after end. The stem of a warship is generally made very massive, and projects under the water so as to form the *ram*.

The longitudinal framing is carried right forward and aft when possible, and the ends of the several frames are connected together across the ship by strong plates and angles, which are called *knees* or *breasthooks*, forward; and knees or *crutches*, aft. Additional supports, introduced to enable the vessel to withstand the heavy blows of the sea in bad weather, are called *panting stringers*, *panting knees*, and *panting beams*, panting being the term applied to the movements which occur in the side plating if sufficient strength is not provided. Where the ends of the ship are very full, or *bluff*, the frames are sometimes inclined, or canted out of the transverse plane, so as to be more nearly at right angles to the plating; such are known as *cant* frames. At the stern a transverse frame, called a *transom*, is in some cases attached to the upper part of the sternpost to form a base for cant frames of the overhanging part of the stern which is known as the *counter*. To assist the beams and bulkheads in holding the decks in their proper positions, vertical *pillars* are introduced in large numbers; but to avoid the loss of space and inconvenience in handling cargo, ordinary pillars are often dispensed with, and special pillars and deep deck girders or carlings fitted instead.

The steel generally used in shipbuilding is known as *mild* steel. It is very tough and ductile, and differs from the *hard* steel, out of which tools are made, in that it will not take a *temper*, *i.e.*, if heated and plunged into oil or water, the sudden cooling has very little effect upon it, whereas with tool steels a great change takes place, the steel becoming very hard, and usually brittle. This quality of tempering depends chiefly on the amount of carbon in the steel, mild steel containing less than ·25 per cent. Steel of greater strength than mild steel is used occasionally in certain parts of warships. The extra strength is obtained generally by the addition of carbon, nickel, or chromium, coupled with special treatment. The quality of the plates and bars used is tested by cutting off strips about 2 inches wide, and bending them double by hammering, or in a press, until the bend is a semicircle whose diameter is three times the thickness of the strip. The strips are sometimes heated and plunged into water to cool them suddenly before bending, and they may be cut from either side or the end of the plate. Strips are taken occasionally and hammered into various other shapes while hot and while cold, so as to ascertain the general quality of the material. To ensure its tenacity, strips are taken and machined to give a parallel part 2 inches in width, of at least 8 inches in length. Two centre-punch marks are made 8 inches apart, and the strip is secured in a testing-machine constructed so that the ends can be gripped by strong jaws which do not injure the parallel part. The jaws are then gradually pulled apart, the amount of the pull required to break the strip being registered, and also the extent to which the strip stretches in the length of 8 inches before breaking. The tensile strength varies between 26 and 32 tons per square inch, calculated on the original sectional area of the parallel part before breaking, and the elongation in the 8 inches is about 20 per cent. The standard strength and elongation required by the principal registration societies have already been given. The steel used for making rivets is similarly tested; and samples of the finished rivets are also taken, and hammered into various shapes, hot and cold, to ensure that the metal is soft and ductile and suitable for the work.

Materials.

The stem, stern-frame, &c., are frequently made of forged iron; but if of steel, they are cast to the form required. These castings are tested by being let fall on hard ground and then slung in chains and hammered all over, when faults of casting are generally discovered by variations in the sounds produced. By this hammering the general soundness of the casting is ensured. To test the quality of the steel in the casting, small pieces, which are cast on for the purpose, are removed and tested in the same manner as just described for the strips cut off from the plates; they are required to give about the same tensile strength, but a little less ductility, say 10 per cent. instead of 20 per cent. elongation in 8 inches.

The sections of the iron and steel bars in common use are shown in Fig. 11, and are named as follows:—

A. Angle bar.
B. T (Tee) bar.
C. Channel bar.
D. Z (Zed) bar.
E. I bar.
F. Plain bulb bar.
G and H. Angle bulb.
I. T bulb bar.
J. Half-round moulding.
K. Hollow moulding.

The vertical, or central, portion in the I, T, and bulb sections is spoken of as the *web*, and varies from about 3 inches to 9 inches in depth; the horizontal parts are called *flanges*; in an angle bar, both parts of the section are called flanges. The flanges vary in width from about 2 inches to 7 inches in the angle bar, and from 3 inches to 6 inches in the others. The thickness varies from about ¼ inch to ¾ inch. These dimensions taken together are called the *scantlings* of such material. The thicknesses of the plates in common use generally lie between ¼ inch and 1 inch. Thicker or thinner plates are obtainable, but are not often used for merchant ships. These plates are of varying sizes as required, the tendency being to use very large plates where possible, and widths of 4 feet to 6 feet are used in lengths of from 40 to 20 feet. Angle bars are used in lengths of from 20 to 80 feet as required, or as may be limited by the means of transport between the steel works and the shipyard.

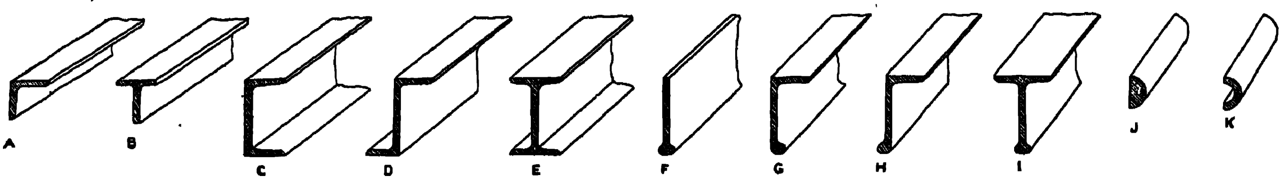

FIG. 11.

The various plates and bars are connected together by means of *rivets* of various forms. Specimens of the common kinds are shown in Fig. 12. The heads and points have distinctive names, as follows:—

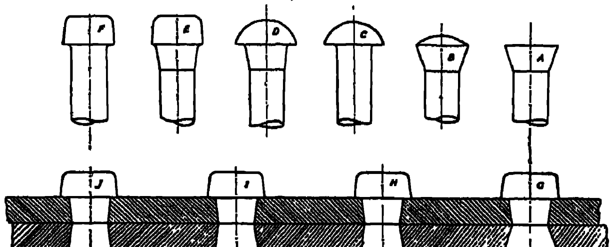

FIG. 12.

(A) Countersunk head, chipped flush.
(B) Ordinary countersunk head.
(C) Snap head.
(D) Snap head with conical or swelled neck.
(E) Pan head with conical or swelled neck.
(F) Pan head.
(G) Countersunk point.
(H) Rough hammered point.
(I) Snap point, hand work.
(J) Snap point, machine work.

The pan head rivet (E) with conical or swelled neck is the most commonly used, as it is convenient to handle and gives good sound work. The rough hammered point (H) is also very commonly used, is very effective, and is readily worked. The pan head (F) and snap head (C), without cones under the heads, are only used for small rivets; the heads (A), (B), (C), (D), are used where considered desirable for appearance sake, but (C) and (D) are also adopted when the riveting is done by hydraulic machinery. The countersunk point (G) is used on the outside of the shell, and in other places where flush work is required. The snap head (J) is used when the work is riveted up by hydraulic machinery, and the snap point (I) for internal hand riveting where desired for appearance, instead of the rough hammered point. The rivets vary in diameter from about ⅝ inch to 1¼ inch, and the lengths are as required to go through the holes and give enough material properly to form the points. The diameter of the rivet is settled according to the thickness of the plates to be connected, being generally about ¼ inch more than the thickness of the separate plates. The distance from centre to centre of the rivets is spoken of as the *spacing*, and is generally expressed in diameters. For connecting plates and bars in the framing, the spacing of the rivets runs generally to 7 diameters; for securing edges which must be water-tight, the spacing is from 4½ to 6 and, if they are to be oil-tight, 3 to 3½ diameters. In butts and edges of shell-plating the spacing varies from 2½ to 4½ diameters.

In some positions rivets like the above cannot be driven into place and properly hammered up; resort is then made to rivets which have screwed points, called *tap rivets*, shaped as shown in Fig. 13. That shown at (B) is used where it is necessary to make

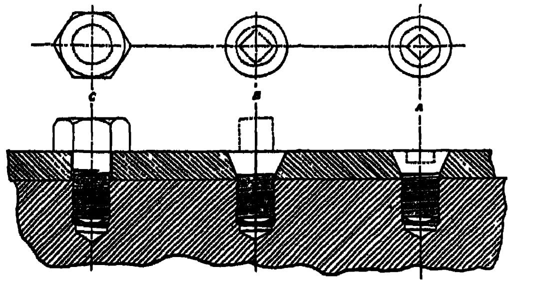

FIG. 13.

the surface flush, but not necessary to remove the rivet for examination of plating; and when hove right up, the square head is chipped off and the surface hammered smooth. In other positions patterns (*a*) or (*c*) are used as may be most suitable.

The machines used in the shipyard have been much improved of recent years. The one most used is the punching and shearing machine, on one side of which plates of all thicknesses up to

2 inches may be cut or sheared to any desired form, while on the other side rivet holes may be punched of any required size.

Machine tools. Special shears are provided with V-shaped cutters for shearing angle bars, but in some cases the cutters of ordinary shears may be replaced by V-shaped cutters for this purpose. When the plates and bars leave the shearing and punching machine their edges are rough and slightly distorted, to remove which it is necessary to plane them. This is usually done by special machines provided for the purpose. In the most modern types the cutters are duplicated and the machine arranged to cut both ways. When it is required to cut a square edge on the flange of an angle bar, which is often done by hand-chipping, a pneumatic chipping machine of recent introduction is frequently used. In shipbuilding a great deal of drilling must be done by hand, but, where it is possible, drilling machines are employed. The most modern forms can drill a number of holes at the same time. For countersunk work it is necessary to make the hole funnel shaped, as will be seen from Fig. 13. This shape is rapidly given to the holes already punched or drilled by means of a special drilling machine, which can be very easily and rapidly manipulated. The use of portable drills, to avoid hand labour, is rapidly increasing, and several types are in use, operated by electric motors, compressed air, or flexible shafting. They are carried to any position required. The hole made by a drill is cylindrical, but that made in the process of punching is conical. On one side of the plate its diameter is determined by the diameter of the punch, and on the other by the diameter of the die, which must be greater than that of the punch. This taper tends to produce close and sound riveting, as the joint is closed both by the knocking down of the rivet and by the contraction of the rivet on cooling. On the other hand, the operation of punching injures the steel in the neighbourhood of the hole, and for work subjected to great stress this deteriorated material must be removed by countersinking or by drilling the hole to a larger size, or the quality of the material must be restored, or partially restored, by annealing. The process of annealing consists in heating the steel to a good red, then allowing it to cool very slowly; during this process parts of the material which have been unduly distressed in working regain their strength by molecular rearrangements in the distressed parts. This process occurs to some extent when hot rivets are introduced into the holes and hammered up. The steel immediately adjacent to the rivet is heated, and afterwards cools gradually as the heat becomes distributed into the body of the plate. In some experiments carried out by the Admiralty in Pembroke Dockyard in 1884, it was found that the effect of punching holes close together, as for a butt-strap, was to diminish the tensile strength of the plates about 20 per cent.; that hot riveting restored about half of this; and that when holes were drilled and countersunk right through, also when holes were punched $\frac{5}{8}$ inch and countersunk right through, so as to enlarge hole to $\frac{7}{8}$ inch in diameter, there was no loss.

In addition to the machines mentioned above, many special appliances have recently been introduced into shipyards for the purpose of economically carrying out definite operations rendered possible by the use of mild steel. Ships built with a bar keel require the garboard strake plates on each side to be flanged on one edge, so as to fit against the bar keel. This flanging was formerly carried out by heating the plates and treating them hot, but now a very powerful machine, called a keel-plate bending machine, and usually worked by hydraulic power, is employed for the purpose with the plate cold. Flanging plates cold has also become general for a variety of purposes. In a bulkhead, stiffening is necessary, and for this purpose angle bars were commonly used; the horizontal stiffeners are now frequently formed by flanging the lower edges of the plates. Instead of fitting an angle bar to connect two plates at right angles to one another, the edge or end of one may be flanged, and half the weight of the angle bar and the rivet work saved. For all such work somewhat lighter flanging machines than the keel-plate bending machine are used; they are generally worked by hydraulic power, but there is no difficulty in driving them by any other means.

Another modern appliance is the scarfing machine, which is used chiefly in connexion with the lapped butts of shell and other plating. Before its introduction it was usual to bring the ends of the plates together and cover the joint with a short plate called a butt-strap, secured to both plates with a proper arrangement of rivets (see Fig. 14). It is now more usual in merchant ships to work overlap butts, some half of the weight of the butt-strap and riveting and other work being saved thereby, although the appearance may not be quite so sightly. The difficulty with this system is that the passing plates on each side have their edges lapped over the ends of the lap-butt, and in order that they may be brought close some machining is necessary; this is called scarfing, *i.e.*, slotting away the corner of the projecting butt so as to produce smooth surfaces for the side laps (see section at A B, Fig. 14). The machine used for this operation is a slotting machine with two heads, so as to slot both edges of the plate at the same time; it is provided with a table which can be adjusted to the necessary bevel, so that the slotting tools may reduce the thickness of the edges operated on in a gradual taper to a knife-edge. A more recent appliance for reducing weight is the joggling machine. As already described, the usual method of working the shell-plating is by alternate inside and outside strakes of plating, the outside plates overlapping the inside plates, and the space between them and the frames being filled in by slips or liners. These liners throughout the ship amount to a considerable weight, and the object of the joggling is to do away with the necessity for them. This is effected by shaping the outside plates as shown in section *b*, Fig. 15. Sometimes the frames are joggled instead of the plates, as shown in section *c*, Fig. 15; the inside plate lies in the recessed portion of the frame formed by the joggling process, and the outside plate on the unrecessed portion, its edge lapping over the edge of the inside plate the usual width. The angle bar in this case must be heated, and the hydraulic press is placed so as to be readily accessible for the handling of the part to be heated. The system of joggling the frames has not been adopted to nearly so large an extent as that of joggling the plates.

Frame-bevelling machines appear to be growing in favour. The machine is placed on rails, near to and across the mouth of the frame furnace, so that it can be readily placed in position for the frame bar to be drawn out of the furnace directly through it, and moved to one side when not required. In the machine a series of rollers, which can be inclined to suit the varying bevel required, operate on the bar. The inclination of the roller is varied as the bar passes along, a dial and pointer giving the angle of bevel at each instant. As the bar passes through, the workman, with his eye on the dial, manipulates the machine so as to give it the required bevel. It is afterwards completed on the slabs, the form being taken from the scrive-board in the usual way.

The shipyard should be supplied with modern machinery of the most approved type, in order to produce the best work at economical rates: rolls for straightening and bending plates, for fairing and bending beams and angle bars; shaping and slotting machines; lathes and milling machines; heavy planing machines. It should also have a blacksmith's shop, saw-mills, joiner's shops, &c., all fully equipped for completing, as far as possible, the work of the yard. The workshops and machines should be distributed so that, as far as possible, the material moves steadily along, as the various operations are performed upon it, to its place in the ship. Pneumatic tools are often preferred for light work, such as chipping, drilling, rimering, and caulking; they are also occasionally used for riveting, but they are not yet much in favour for this class of work. Hydraulic power is particularly well adapted for heavy presses, such as for keel-plate flanging, for punching and shearing, and especially for punching manholes and lightening holes in plates, and for heavy riveting. It is also very successfully applied for pressing to shape a great variety of small fittings made of steel or iron. For such machines as rolls, ordinary shears and punches, winches, &c., separate steam engines are still frequently fitted, but there is a very marked tendency to replace all these by electric motors. Electric power for driving all the machinery has been introduced into many shipyards. It has many advantages: all the power required in the yard may be generated in one building in any position, containing the boilers, steam engines, and electric generators, and the whole may be designed and worked so as to secure great economy. The current is supplied either to motors directly driving the heavier or outlying machines, or to motors driving a line of shafting where the machines are of a lighter character and are arranged in compact groups. Fixed machines can be placed where most convenient for the work, without any reference to the position of the boilers or other machinery, and a large number of machines can be very readily made portable for the lighter classes of work. The power may be transmitted with but little loss, whereas with steam-driven machines at a distance from the boilers, lines of steam piping must be introduced, and loss of power is entailed. The saving which the system of electric driving effects over that of steam driving in the consumption of coal in a large shipyard is considerable, and is claimed by those who have adopted it to be sufficient to justify the large capital expenditure required to convert a shipyard from the latter system to the former.

As the plates, beams, angle bars, Z bars, &c., are delivered, they must be stored in convenient racks, with marks showing for what purpose they are intended, so that they can be readily identified and removed without loss of time. When required, they are taken from the racks, and the edges, butts, and rivet holes carefully marked upon them before they are taken to the machines where the shearing, punching, drilling, shaping, &c., are carried out, after which they are taken to their proper position in the ship.

In many shipyards great attention has been given to the questions of the economical handling of the material, and very costly and novel appliances are to be found in these yards for the purpose. As an example mention may be made of the overhead cranes fitted at the Union Ironworks of San Francisco. A framework of

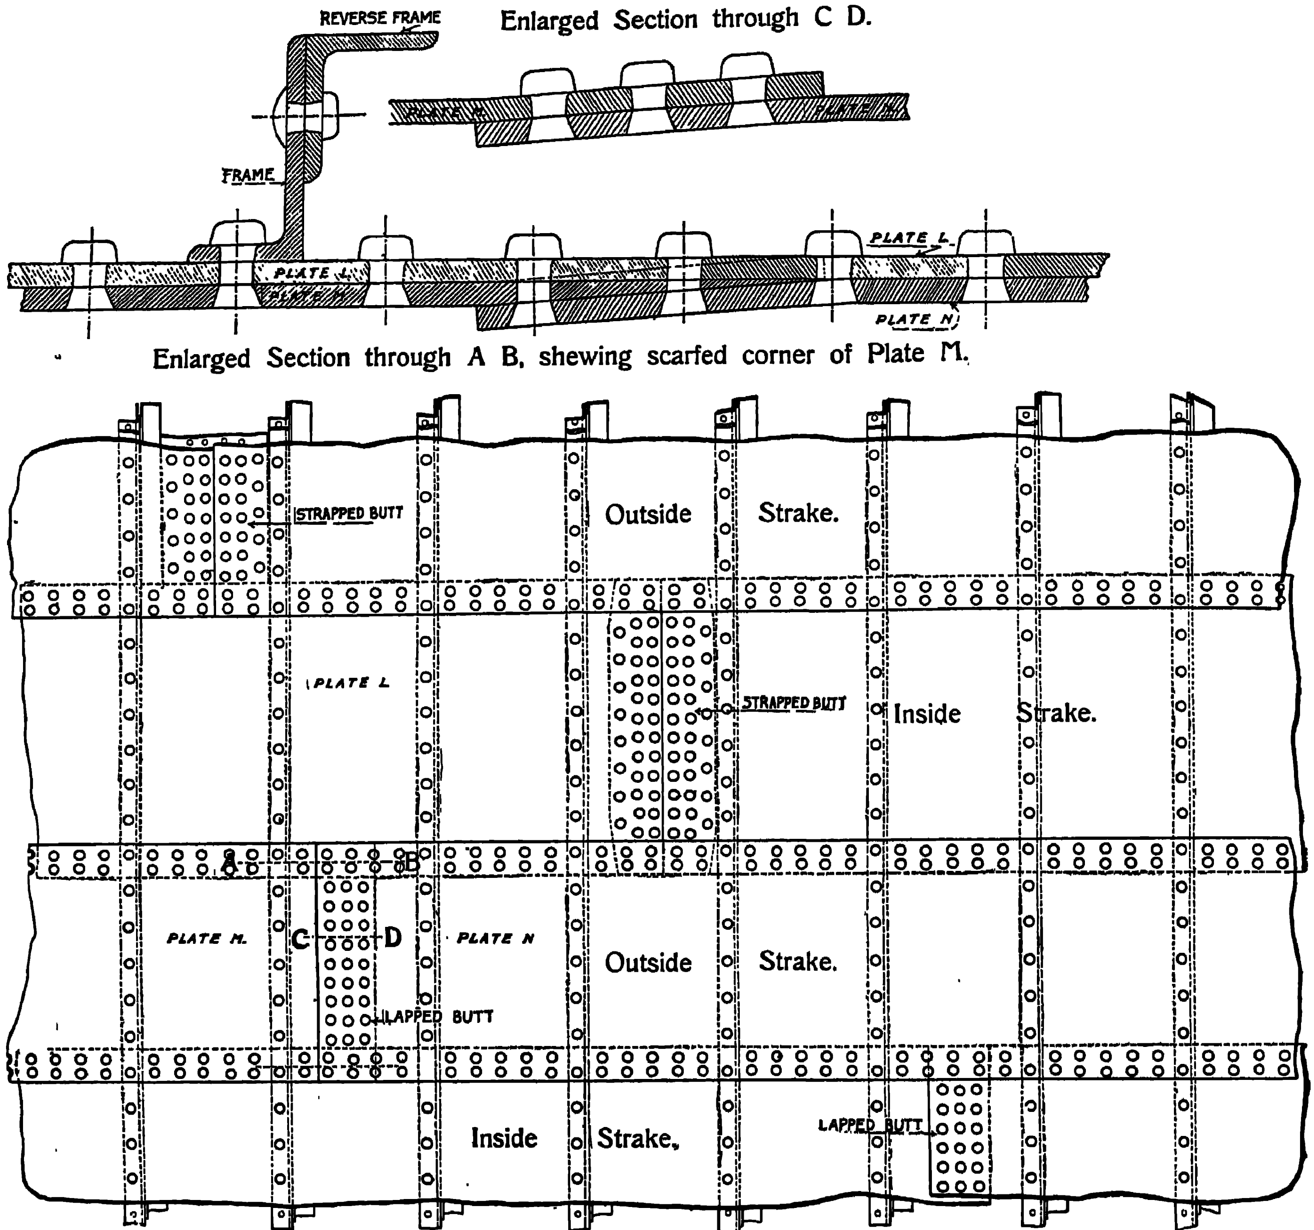

FIG. 14.—Details of shell-plating.

wood is built up over the entire building berth, the structure being well braced in all directions for carrying two travelling girder cranes. There are four building berths fitted in this manner, and the latest has a length of 408 feet, a clear breadth of 80 feet, and clear height of 72 feet. A swing crane of 50 feet spread at each end of the erection increases its effective length to 500 feet. Each of the travelling girders carries a trolley, with motion transverse to the ship; five tons can be so lifted, and parts of the ship's structure not exceeding this weight can be taken from the ground anywhere in the neighbourhood of the structure and conveyed to any desired spot in the ship. The driving power is electric. The longitudinal travel of the girders is 180 feet per minute; the transverse travel of the trolley and speed of lift, each 90 feet per minute. A manila rope is used for hoisting, except for plates under the bottom and counter, where a wire rope is used.

Cranes.

At Newport News, in Virginia, the structures are differently arranged, being on the cantilever travelling-crane principle. There are five such structures in the yard; three of them are wood, the last two of steel. The largest is 700 feet long. One trestle structure, or gantry, serves two building berths, and runs longitudinally between the two. On the gantry is mounted a double cantilever crane, having an effective reach of 95 feet on each side of the centre; this outreach is sufficient for a ship 70 feet broad on each side of the trestle. The height of the cantilever above the ground is some

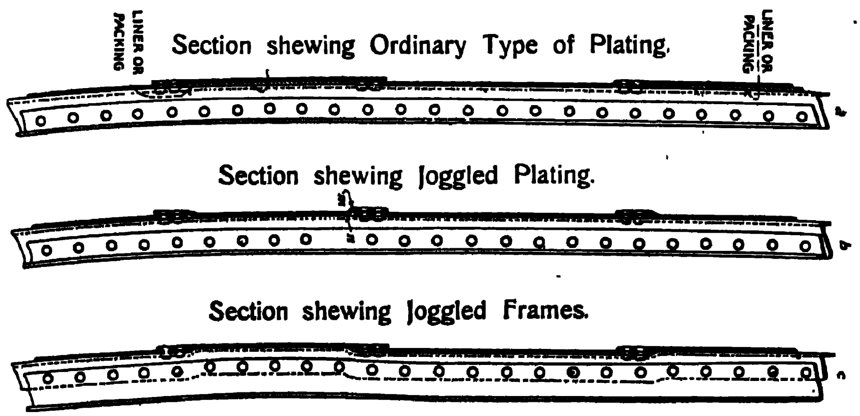

FIG. 15.—Methods of working shell-plating.

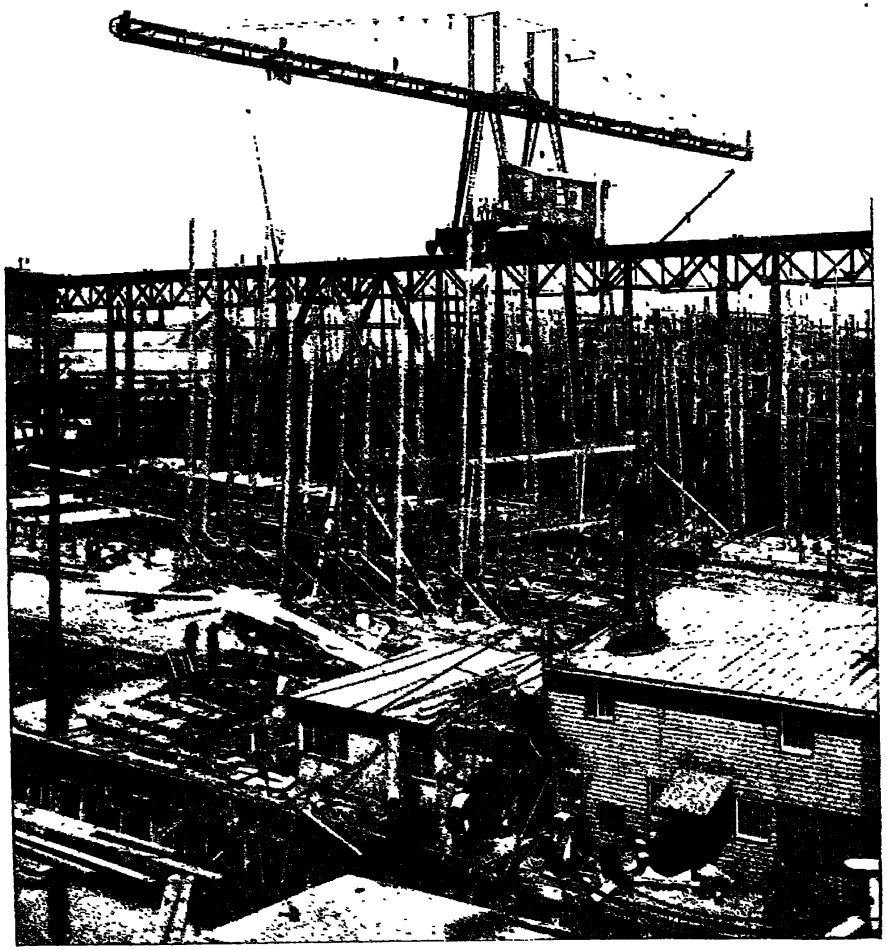

FIG. 16.—Gantry at Messrs Cramp's Shipbuilding Yard, Philadelphia.

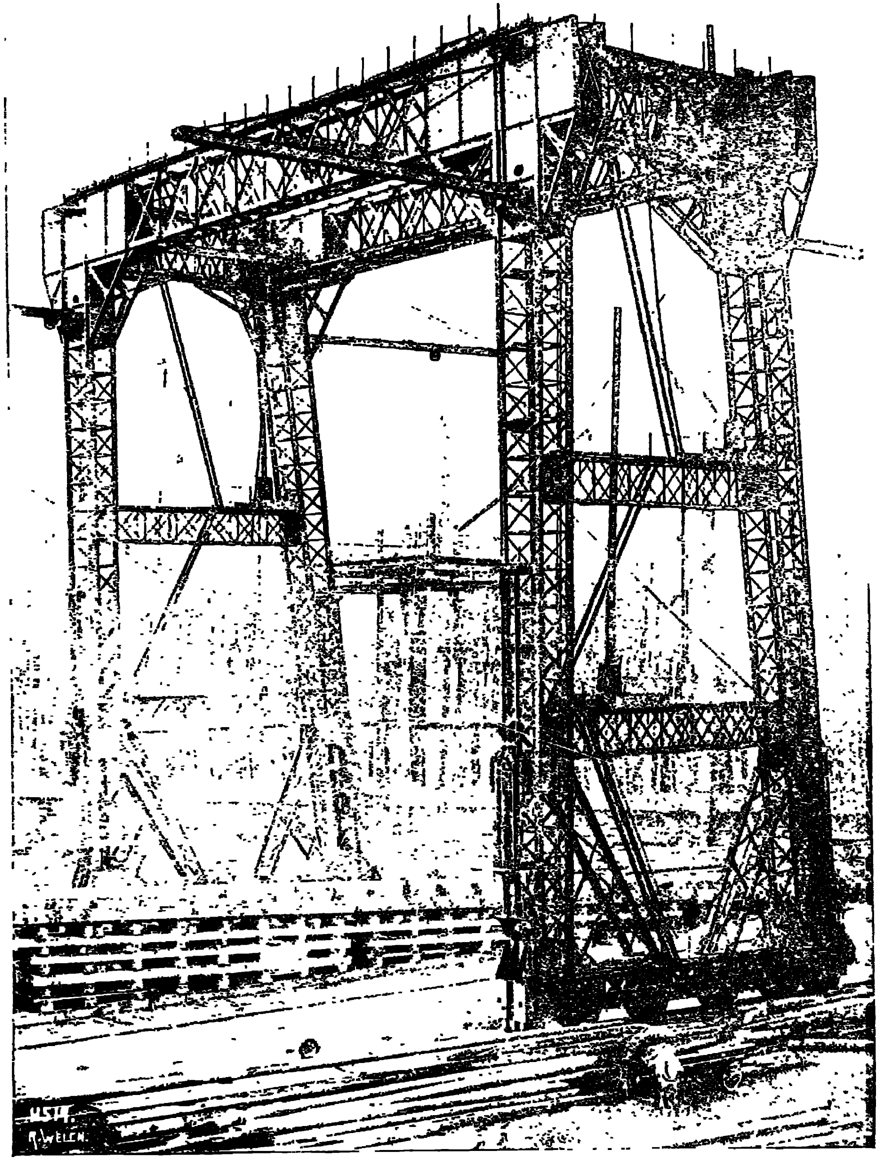

FIG. 17.—Gantry at Messrs Harland and Wolff's Shipbuilding Yard, Belfast.

90 feet, the load that can be raised is 15 tons, and if necessary a bulkhead up to that weight can be lifted bodily into place. The speed of lift for this weight is 100 feet per minute, and for lighter loads 700 feet per minute. The speed of the trolley along the cantilever is 400 to 800 feet per minute, and of the whole crane longitudinally is 400 to 700 feet per minute. All movements are made by electric power. Similar gantries and arrangements are used in other American shipyards. The view shown in Fig. 16 (Plate I.) represents one of these structures as fitted in Messrs Cramp's shipyard in Philadelphia.

At the yard of Messrs C. S. Swan and Hunter, on the Tyne, similar structures have been erected since 1894: besides carrying cranes, these have standards and stiffening girders, from which ships under construction are shored for fairing. Roofs and sides are fitted to protect the ship, and the workmen engaged in building her, from the weather. The side supports are three in number, and serve for two berths; they are formed of steel lattice-work, with standards mostly 20 feet apart. The clear height of roof is 83 feet, and clear breadth of berths 68 feet and 73 feet; a roadway on the ground level is left free on each side of the berths inside the standards. Two revolving 3-ton electric cranes travel along paths suspended from each roof; their jibs have sufficient radius to lift material from the roadways and deposit it at the centre of the ships building. The longitudinal speed of these cranes is 300 feet per minute; speed of lift, 100 feet per minute. A third berth is served by a travelling cantilever crane on top of the adjoining roof. At Messrs Harland and Wolff's yard at Belfast another modification was introduced in 1897 (see Fig. 17, Plate I.). In this case the structure takes the form of a travelling gantry or bridge over the building berth, the legs running on rails at the ground level. The gantry, which is driven by hydraulic power, has three traversing cranes and four 4-ton swing cranes. It was designed to facilitate the lifting of plates and portions of the structure into position, and also to support the hydraulic riveting machines and other appliances for the carrying out of the work. The success of the appliances, first used in the *Oceanic*, has led to a further extension for other ships in hand.

Course of construction. The first steps taken in the construction of a vessel, after the receipt of the design, drawings, and specifications, are with the view of obtaining the necessary particulars for ordering the material, making the moulds, and supplying other information for shaping the various parts of the framing. A half-block model is prepared of the exterior of the vessel, on a quarter-inch or other convenient scale. On this the positions of the frames, deck edges, the edges of the shell plating, and other details are carefully drawn in, and then the butts of all the keel and shell plating are arranged, the sizes of the plates are measured, some allowance is made for cutting to shape, and the plates and many portions of the framing are at once ordered. Another block model is generally made showing the form of the top of the ballast tanks, or in warships the shape of the inner bottom. In the case of a warship a block model will also be made of the protective deck, the plates arranged thereon, and ordered by measurements so obtained.

While the material is being ordered, the laying off the vessel, which consists of enlarging the sheer drawings to full size on the floor of the mould loft, and deducing from it the shapes of the various parts of the framing, is proceeded with. The mould loft is a large room floored with stout boards, planed smooth and carefully painted so as to produce a good hard surface; this is used as a large drawing-board, and on it nearly all parts of the vessel are drawn to full size before the work proceeds. The sheer drawing is transferred to the floor by measuring the ordinates or offsets from the ¼-inch or ½-inch scale, drawing and setting them off full size in their proper relative positions. Battens are bent to the curves passing through the spots thus obtained, and the lines are drawn and *rased* or *scratched* in, after being *faired*. The process of fairing is performed by laying off a series of vertical, horizontal, and oblique sections of the outside surface of the ship. These are modified as necessary to give fair curves, and the ordinates are adjusted accordingly. As soon as the form is faired, moulds or templates are made, to enable the patterns of the stem, stern frame, and shaft brackets (if for a twin-screw vessel) to be completed by the pattern-makers, which, to prevent delay in launching, must be completed and sent to the steel-makers at an early date. For very large vessels the sheer is in some cases partially faired on paper, to save work on the floor, by reproducing the drawing on a large scale, say ½ inch or ¾ inch to the foot, and fairing the lines as already described for the process on the floor. In some yards laying off on a large scale on paper is relied on almost entirely, and very little full-sized work on the floor is considered necessary. Before the lines are rased in, a displacement sheet must be fully worked out from the lines on the floor, to ensure that the correct displacement and position of CB and metacentre are obtained, otherwise the ship may not float at the waterline intended, or with the desired initial stability. Moulds for a great many of the plates and angle bars can now be made, such as the various flat and vertical keel plates and keelsons, intercostals, margin plates, the stringer plates of the decks, the frames, and bulkheads. They are often made separate in thin wood; but it is a common practice to make a copy of a large part of the body plan, showing the shapes of the frames, floors, reverse frames, &c., on a large wood platform prepared for the purpose, called a *scrive-board*, which is placed near the angle-bar furnaces for the use of the angle-smiths; and by its use the frames are set, instead of using separate wooden moulds for each frame. While the work on the scrive-board is proceeding, moulds for other parts are put in hand at the mould loft, such as the beams of each deck, the keelsons, girders, and stringers.

The practice in regard to laying-off and mould-making varies considerably in different places; some prefer making moulds at the ship when possible, some use the mould loft to the fullest extent, and others are content with the scrive board and little else. For instance, in the American Lake shipyards templates are very carefully and ingeniously made for the framing, one set sufficing to mark off all the frames over the greater portion of the ship's length. In a similar way, one template is made for each strake of plating, and used to mark off the whole of the plates of that strake, a slip mould being used when they begin to depart from the parallel midship body.

In the drawing office, arrangements of the plating and angle bars required in all parts of the vessel are worked out, with the view of ordering the materials at the earliest possible date. In many cases the sizes required can be obtained from the model, or, as already stated, from the floor, but in many others they have to be measured from these working drawings. All the drawings of the structure and of the fittings must be pushed on and issued to the shipyard in good time. Very much of the success achieved in actual building will depend upon the efficiency of the drawing office, and the rapidity with which the various detailed working plans can be supplied for guidance. These plans must be accurate and complete, and must be ready as soon as required. The drawing-office staff has the oversight of weights actually worked into the ship, a careful record of which should be kept. Each firm has its own system of work in these departments, but experience shows that the more thorough and systematic the work in the drawing office and its adjunct, the mould loft, the better the general result. Another important record is the cost of materials and labour. In all shipyards careful account is kept of workmen's time, whether employed on piece or by the day. Many different systems are in vogue; but whatever the system, the aim is to record the cost of the labour in each trade, and the detailed cost of various parts of the ship.

Laying keel blocks.

While the work connected with laying-off and obtaining materials, &c., is going on, the shipwrights, assisted by handy labourers, prepare the ground for the keel blocks, lay the *blocks* at the proper height and inclination, and secure them against being floated away by the tide or being accidentally tripped while the ship is building. The blocks consist of several pieces of tough rectangular timber, 4 to 6 feet in length, and laid on each other to the height required. The top block is called the *cap-piece*, and is of oak or other hard wood. The blocks are spaced about 4 feet apart for ships of medium size, and somewhat less for ships of large size. They are usually placed upon a longitudinal bed of timber, which remains embedded in the ground for successive ships: the ground should be hard, or very well piled, otherwise the blocks may sink when weight becomes concentrated over them during building, and difficulty arises from the keel, or the propelling shafts, drooping from a straight line. The upper surface of the blocks must be at such a height from the ground that men, especially riveters, can do their work with facility under the bottom of the vessel, that the launch can be fitted, and that when launched the vessel may move down into the water without striking the ground. The last named is a most important consideration; and thus it comes about that the first thing to be settled, before the blocks are laid, is how the vessel is to be launched. The tops of all the blocks are accurately adjusted to a plane surface sloping about ⅝ inch in a foot from bow to stern. The shipwrights at the same time prepare the uprights for the staging, and erect them around the building berth in suitable position with the first line of staging, which will be required at an early period in the ship's construction. The platers and angle-smiths begin to prepare the keel, framing, bulkheads, &c., as soon as the material is delivered and the laying-off and mould-making are sufficiently advanced for the purpose. The actual building generally dates from the first work of this character.

Keel and frames.

The keels of small vessels usually consist of a stout flat bar placed vertically and attached to the garboard strakes by through rivets. Occasionally the keel consists of a vertical centre through-plate, with side bars at its lower edge. In large merchant ships, and in war vessels, the keel usually consists of a wide horizontal plate running along the centre line of the bottom, the sides being turned up as necessary to follow the shape of the bottom (see Figs. 26 and 27, Plate II.). The framing varies very considerably with the size and type of the ship, as already described. In small vessels a frame usually consists of an angle bar, called a *frame bar*, extending from gunwale to gunwale, to which is riveted a bar, also continuous from gunwale to gunwale, called a *reverse bar*, in such a way as to form a built-up Z bar, and between these floor-plates are introduced across the bottom, to give the required strength when resting on the ground or on the blocks. Sometimes the frame consists of a Z bar, in which case the *reverse bar* is not required in the vicinity of the floor-plate. Sometimes angle bulbs are used for frames, as in the case of oil steamers, where internal ceilings are not required. The process of constructing a complete frame of angle bars and plate is as follows:—From the scrive-boards the shape of the section at the frame is transferred to the bending blocks or slabs, the outline being drawn in with chalk; the necessary preparation is made, and the frame bar is drawn from the furnace, and while hot bent to its shape and given the required bevel. The reverse bar is prepared in the same way, except that the inner edge of the frame and floor must be worked to. The floor-plate has to be cut to shape. In large ships the *frame bars, reverse bars,* and *floor-plates* will be in two, or even in three, pieces; in this case the butts are kept some distance from the middle line, and are *shifted* in alternate frames, so as not all to lie in the same fore-and-aft lines. The butts of both frame and reverse bars, as well as those of the floor-plate, are butt-strapped, to maintain as much as possible the strength of the structure. The frame bar, floor-plate, and reverse frame bar all being set, they are placed together in their respective positions over the outline of the frame on the slabs or scrive-boards, the final adjustments made and rivet holes marked and punched, and the work secured together and riveted up.

When the keel is in place, and as far as possible riveted, the frames, bulkheads, and beams, which have been made ready by the iron-workers, are brought to the building slip and got into position by the shipwrights. They are held in place and faired by means of shores and *ribbands*. The latter are made from straight-grained timber of considerable length, sawn out in long straight pieces of square transverse section. They hold the frames in position until the outside plating is riveted. Upon them are marked the lines at which they must be crossed by each frame, and they are bent round and attached to the frames in a fore-and-aft direction at certain heights, which are marked on the frames at the scrive-boards. Some four or more ribbands are used each side of the ship. As the work proceeds, the positions of the frames and ribbands are checked continuously, their positions being maintained by shores from the ground, or some structure prepared for the purpose. Except in small vessels, the beams are not attached to the frames before they are erected, but are hoisted into place as soon as possible afterwards.

The bulkheads are put together on some convenient flat surface, sometimes on the scrive-board or a similar platform constructed for the purpose. If of large size, they are transferred piece by piece and erected at their proper positions in the ship; but whenever possible, they are riveted up and hoisted into position complete. The stem and sternpost are obtained from the forge or foundry and erected at an early stage of the work. The part of the stern abaft the transom is sometimes framed separately on the ground before being erected in the ship. The centre keelson is generally worked intercostally between the floors, but it has continuous parts, usually angle bars, above the floors. Each intercostal plate is secured by angle bars or flanged edges to the floors and to the flat keel plate. Sometimes it is continuous, especially in large ships and in warships. The frames are then cut by it, and the floor-plates are attached to it by short angle bars. After the centre keelsons, the side keelsons and side and deck stringers are fitted. The steel pillars are substituted for the shores supporting the deck beams, being riveted at their heads to the beams and at their heels to the keelson, inner bottom, or tank top.

While the work is proceeding, the shipwrights make the stages, put up gangways and ladders for carrying on the work, fit extra blocks and shores, or remove and replace them as may be required. They line off all plate edges on the frames, the overlap being usually painted in with white paint, ready for the platers. They also erect the stem, sternpost, rudder, and shaft brackets, or struts in twin-screw vessels.

In a ship fitted with an inner bottom the procedure is somewhat more complicated, as the transverse frames cannot be lifted into place as a whole. There are many varieties in the arrangements in such cases; one frequently adopted is shown in Fig. 21, in which the inner bottom extends out to the turn of the bilge. This figure also shows the general construction of the vessel, including the framing at a bulkhead and elsewhere, the bulkhead itself with all its stiffening bars and attachments to the sides of the vessel, and the inner bottom. At the centre line, immediately over the flat keel plates, there is a vertical girder, the full depth of the double bottom, connected to the flat keel plate and to the centre plate of the inner bottom by continuous double-angle bars. This centre girder may or may not be water-tight, according to the desired tank arrangements. The transverse frames are in four parts: the two lower extending on either side from the centre girder to the margin plate of the double bottom, which is a continuous girder of special construction; and the two upper, from the margin plates to the topsides. The lower parts consist of a floor-plate with angle bars at its edges for attaching it to the outer and inner bottoms, the centre girder, and the margin plate. At the bulkheads these floor-plates are solid, and the angle bars are united and made water-tight; elsewhere they are lightened by holes, and the angle bars at their upper and lower edges and ends are separate pieces. The two upper parts of the transverse framing consist of a frame and a reverse bar, each having a deep and a shallow flange, and are riveted to one another along their deep flanges, with their shallow flanges standing the reverse way to one another. The shell-plating is attached to the shallow flange of the frame bar. Between the centre girder and the margin plate on each side of the ship there are two intercostal girders, the plates of which are connected by short angle bars to the floors and to the shell and inner bottom plating; and between the margin plates and the lower deck on each side there are three stringers, consisting of intercostal plates attached by short bars to the outer plating, and three continuous angle bars riveted to part of the intercostal plates which extend beyond the reverse bars.

In the course of erection, after the flat keel plate is laid upon the blocks, and the centre girder placed upon it, the two lower parts of the frames, which have been constructed alongside, are put into position, their outer ends being carried by ribbands shored from the ground. The intercostal girders and margin plates are then fitted. The lower edge of the margin plate is brought close to the outer edge of the frames, and is connected by a longitudinal angle bar to the shell-plating, while its upper edge is flanged for the purpose of being attached to the inner bottom plating. The ship at this stage gives the impression that a flat pontoon is being constructed.

When the margin plates are up and faired and, as far as desirable, riveted, the upper parts of the frames on each side are erected and the fairing proceeded with as before. The beams are now got into place, also the side and deck stringers. As will be seen, the margin plate cuts completely through the transverse frames, and special brackets are provided to maintain the transverse strength. The chief advantages derived from cutting the frames by the margin plate are the cheapness with which water-tight work is secured, and the rapidity with which this part of the work can be proceeded with.

As soon as the keelsons and stringers are riveted, and the ship by their means sufficiently stiffened, the outside or shell plating is

commenced. The plating squad is supplied with a drawing showing the disposition of the butts in each line of plates; light wooden moulds or templates are then made, giving the exact shape of the edges and butts, and the positions of all the rivet holes in the frames. From these moulds the edges and butts and the holes are marked off, the holes are punched, and the edges and butts sheared and planed. The plates are then rolled to shape, furnacing being resorted to only when the curvature is too extreme to be obtained with the plate cold. The usual arrangement of the plating is that of inside and outside strakes alternately (see *a*, Fig. 15). The inside strakes, which are worked first, are templated off the ship, and lie directly on the flanges of the frame bars. The outside or overlapping plates are then worked, and are templated from the place they are intended to occupy on the ship. They are kept at the proper distance from the frames by liners or slips of the same thickness as the adjacent inside plates. Towards the ends of the ship the number of strakes of plating must be reduced, as the girth along the frames is much less than over the midship portions. Stealers are introduced for this purpose; they are single plates, which at one end receive the butts of two plates, and at the other the butt of only one. By them two strakes are merged into one.

Shell or outside plating.

The number of plates requiring to be furnaced is small in comparison with the whole number, but there are always some at the after end of the ship, especially in the neighbourhood of the boss (for the stern tube) and the counter, and a few at the forward end of most ships. As each plate is got ready, it is taken to the ship, hoisted into position, and temporarily secured by the platers by means of bolts and nuts. As the work of plating proceeds, and the weight of the ship increases, extra shores are put into place, and bilge blocks erected by the shipwrights, to keep the structure to its shape and prevent local and general "unfairness." The shell-plating in way of the intended bilge blocks is completed at as early a period as possible, and painted, so that when once the bilge blocks are in place they need not be disturbed until immediately before launching. While the platers are at work on the shell-plating, other squads of riveters are engaged on the deck-plating and internal work, such as the bunkers, engine and boiler bearers, the shaft tunnel, casings, and, in the later stages, the hatches, houses on deck, &c., and as much as possible of the internal work is done before the shell shuts out the daylight. As the work is completed by the platers, it is ready for the riveters and caulkers; and these trades follow on without delay, except in some parts of the casings and decks in way of the machinery, which are left portable, and taken down after the launch, to allow the machinery to be put in place.

The platers usually work in squads, composed generally of three platers, a marker-boy, and a number of helpers or labourers, the number of whom depend on the size and weight of the plates, and the nature of the work to be done on them, and also on the facilities of the yard for handling such material. On the work of a large vessel many of these squads would be employed. The riveters also work in squads, a squad consisting of two riveters, one holder-up, and one heater-boy, with sometimes a catcher, *i.e.*, a boy to pass on the heated rivets when the distance from the rivet-hearth is great. Pneumatic riveting has not made great progress in Great Britain. Hydraulic riveting to a limited extent is adopted, especially in the case of work that can be taken to the machine, such as frames, beams, and other parts; but in shipbuilding the large proportion of the riveting is done by hand. In the Royal dockyards platers' work is done by shipwrights, and riveting is not considered a trade, though regarded as skilled labour. Shipwrights also lay the blocks, erect the ribbands, shore and fair the ship, but labourers construct the stages. Drillers' work consists in drilling by hand holes which it is not convenient or possible to punch or drill by machine; they also rimer out and countersink punched and drilled holes when this is necessary. Portable electric or pneumatic drills are used when possible in some shipyards, and three-cylinder hydraulic engine drills are employed for some purposes, such

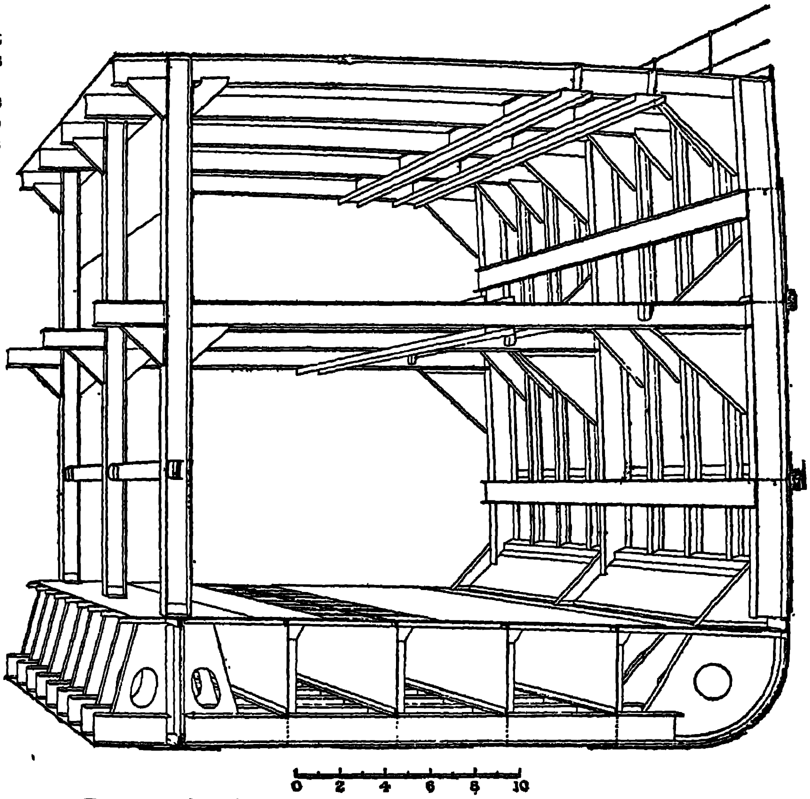

FIG. 18.—Modern Great Lake Cargo Steamer; midship portion, in perspective.

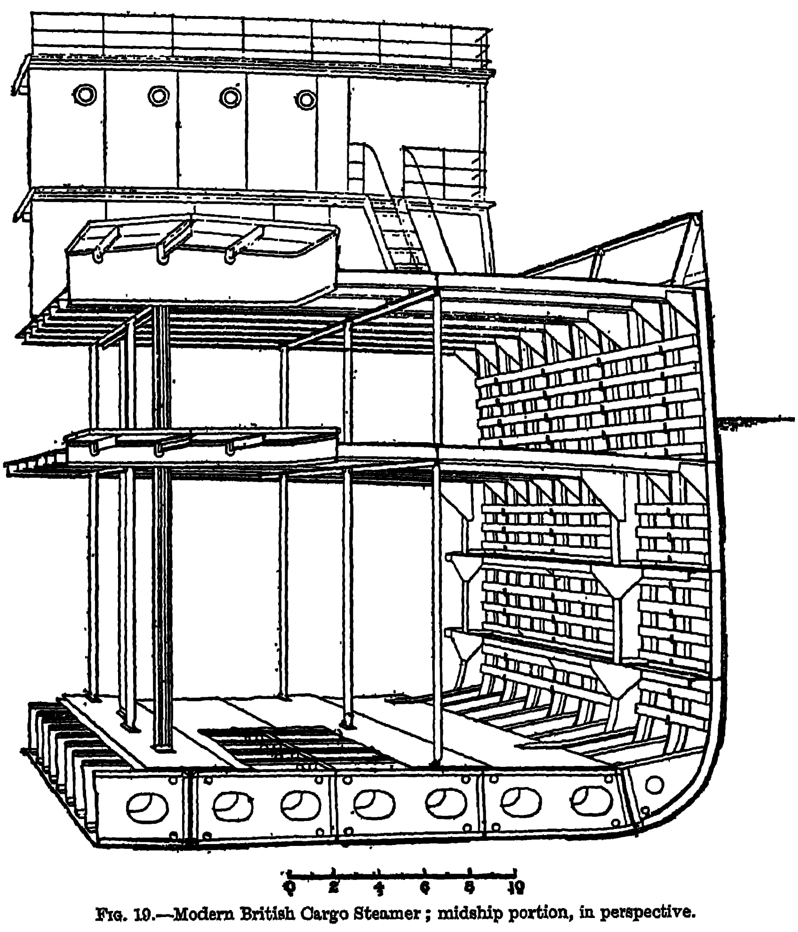

FIG. 19.—Modern British Cargo Steamer; midship portion, in perspective.

as in cutting armour bolt holes in thick plating behind armour. The caulkers follow closely upon the riveters, and generally work singly. A very important part of a caulker's duty is water-testing. In the large oil-tank steamers possibly 8000 tons of water are used for testing one ship alone, and about the same amount for a large war vessel. This water is pumped from the sea or river into the compartment to be tested. In the case of an oil vessel, each compartment is filled right up, and a pressure put on by means of a stand pipe, carried for a considerable height above the highest part of the tank; any leakage found must be made good by the caulker, and the tank re-tested until it is perfectly water-tight. The double bottoms of merchant ships, and the smaller compartments and double bottoms of war vessels, are filled up and tested by a head of water rising a few feet above the load water-line. It is not usual to fill all the larger compartments, such as boiler and engine rooms in war vessels, or the machinery compartments and cargo holds in merchant ships; but water at a high velocity is played on the bulkheads by hose, to test the water-tightness and the strength. An occasional test, however, is made by filling a typical large compartment with water to a height of some feet above the load water-line. Angle-smiths form beam knees where these are welded, and generally all angle bar work where heating in a smith's fire is required. It is usual to defer the painting of certain parts of the steel structure of a ship as long as possible, so that ordinary red rust may form and dislodge the black mill scale which is answerable for a great deal of corrosion in steel ships, as in certain circumstances it forms a galvanic couple with the steel plate. For warships the British Admiralty requires the removal of this scale from these parts by immersing the plates in a weak solution of hydrochloric acid. Red and white lead, oxide of iron, and oxide of zinc form the bases of most of the paints used on steel ships.

Structural Arrangements.

The following are particulars of ships in course of construction at New London (Conn., U.S.A.) on the *longitudinal* system:—"The great centre girder, which in all vessels prior to these has been in the form of an I girder, is formed of a double II or box; that is, these vessels have two vertical keels instead of one. The girder is of the same depth as the double bottom (6 feet). On each side of this girder there are several other vertical longitudinal members, having the plating on the top, forming the tank top, and the shell-plating below, forming the bottom of the tank. This tank or double bottom is 6 feet deep for the greater part of its length, and is increased at the extremities, where it merges into the fore-and-aft peaks at the collision bulkheads. The whole of this space can be filled with water when desired, to sink the ship to a suitable draught when making a voyage without a cargo or with a very light one, at the same time allowing the ship to keep afloat whenever the outer shell or skin has been pierced by rocks or by colliding with other vessels. This bottom girder or double bottom forms the 'backbone' of the ship, from which the great frames spring or extend up to the weather deck, about 60 feet above the keel. The frames are made of channel steel spaced 30 inches apart, but as they near the extreme ends they are spaced closer, and are composed of angle bars riveted together. At certain parts of the structure, where the heave of the sea will tend to strain the ship, the frames are double and made very strong. The outer surface of these frames is covered with a shell of steel plates averaging about 1 inch in thickness. These enormous plates are arranged to give a maximum of strength, and the riveting of them to the frames and to each other is receiving the utmost care.

"These ships have a continuous longitudinal bulkhead on the centre, extending from the inner bottom to the main deck. The side plating of the shell, with this longitudinal bulkhead, form three vertical members of the entire structure. The upper flanges of the girder are formed by the upper and main decks, which are laid with heavy steel plates. This great girder is designed to support a full cargo when suspended by long waves of the sea at either end. The side girders are kept in place by three intermediate decks between the tank and the main deck, making in all five complete decks, each covered with heavy steel plate. The beams supporting all these decks are of channel steel, and fitted to every frame by large bracket plates. One of the many notable features in the construction of these vessels is the distribution of the water ballast. Various conditions of trim and safety can be obtained. The double bottom is divided longitudinally into three water-tight divisions and transversely into about twelve, making in all thirty-six separate tanks. In addition to these there are the fore-and-after peak tanks, and side tanks between the main and 'tween decks, about one quarter of the vessel's length from either end. The latter tanks are really fitted for the purpose of controlling the ship's stability and seaworthiness.

"The vessels are divided transversely into thirteen water-tight compartments, while the longitudinal bulkhead is water-tight in the machinery space, which makes in all fifteen water-tight compartments. The engine-rooms are completely independent of each other; so are the boiler-rooms; but access is had from one to the other by water-tight doors. The coal can gravitate direct to the stokehold floor. The method of pillaring is somewhat novel, and has never been attempted before by any American shipbuilder. . . . Strong girders run under the transverse beams and are supported at wide intervals by built stanchions. By this means the least possible trouble is experienced in stowing the cargo. . . . The building-slips rest upon a solid granite ledge, which at a suitable declivity runs down to the bank of the Thames river. Opposite the yard there is over 60 feet of water, and it is proposed to run the launching-ways about 300 feet from the shore-line into the water. The vessels will be the heaviest ever launched."

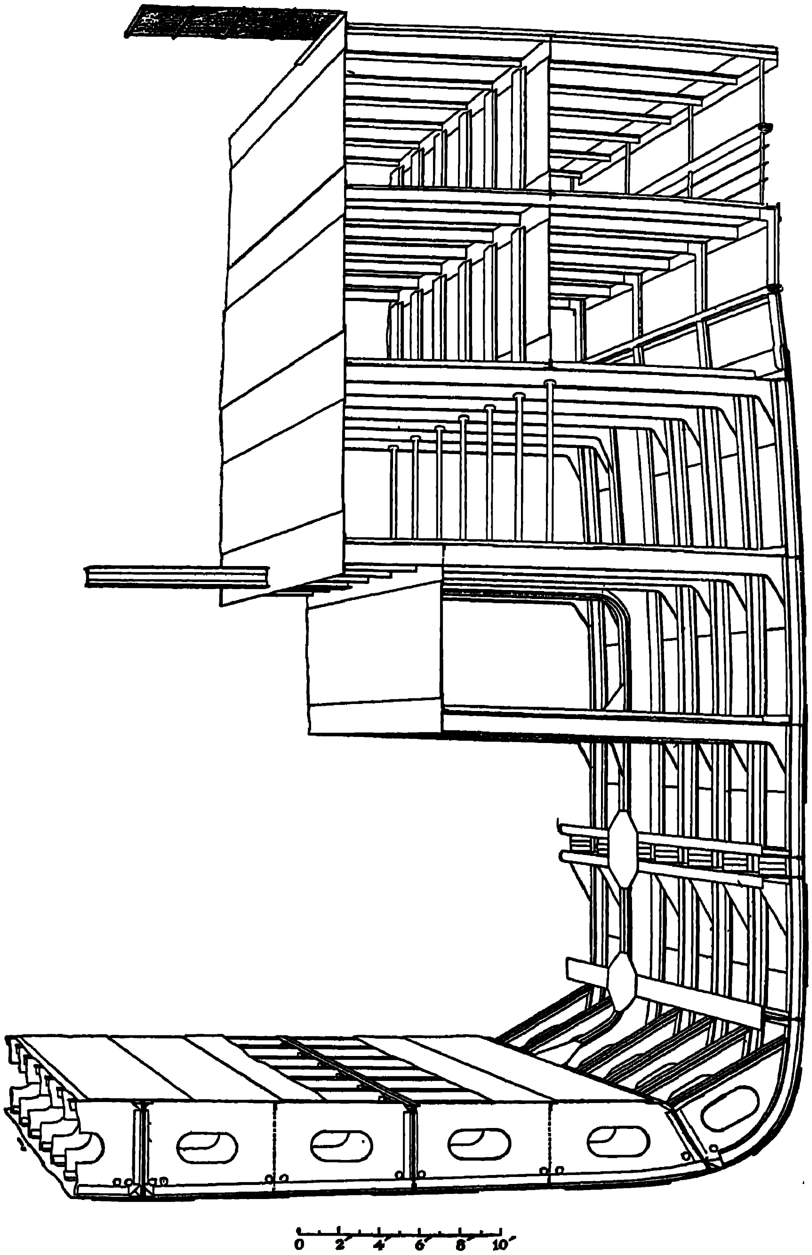

FIG. 20.—Cunard Liner *Campania*; midship portion, in perspective.

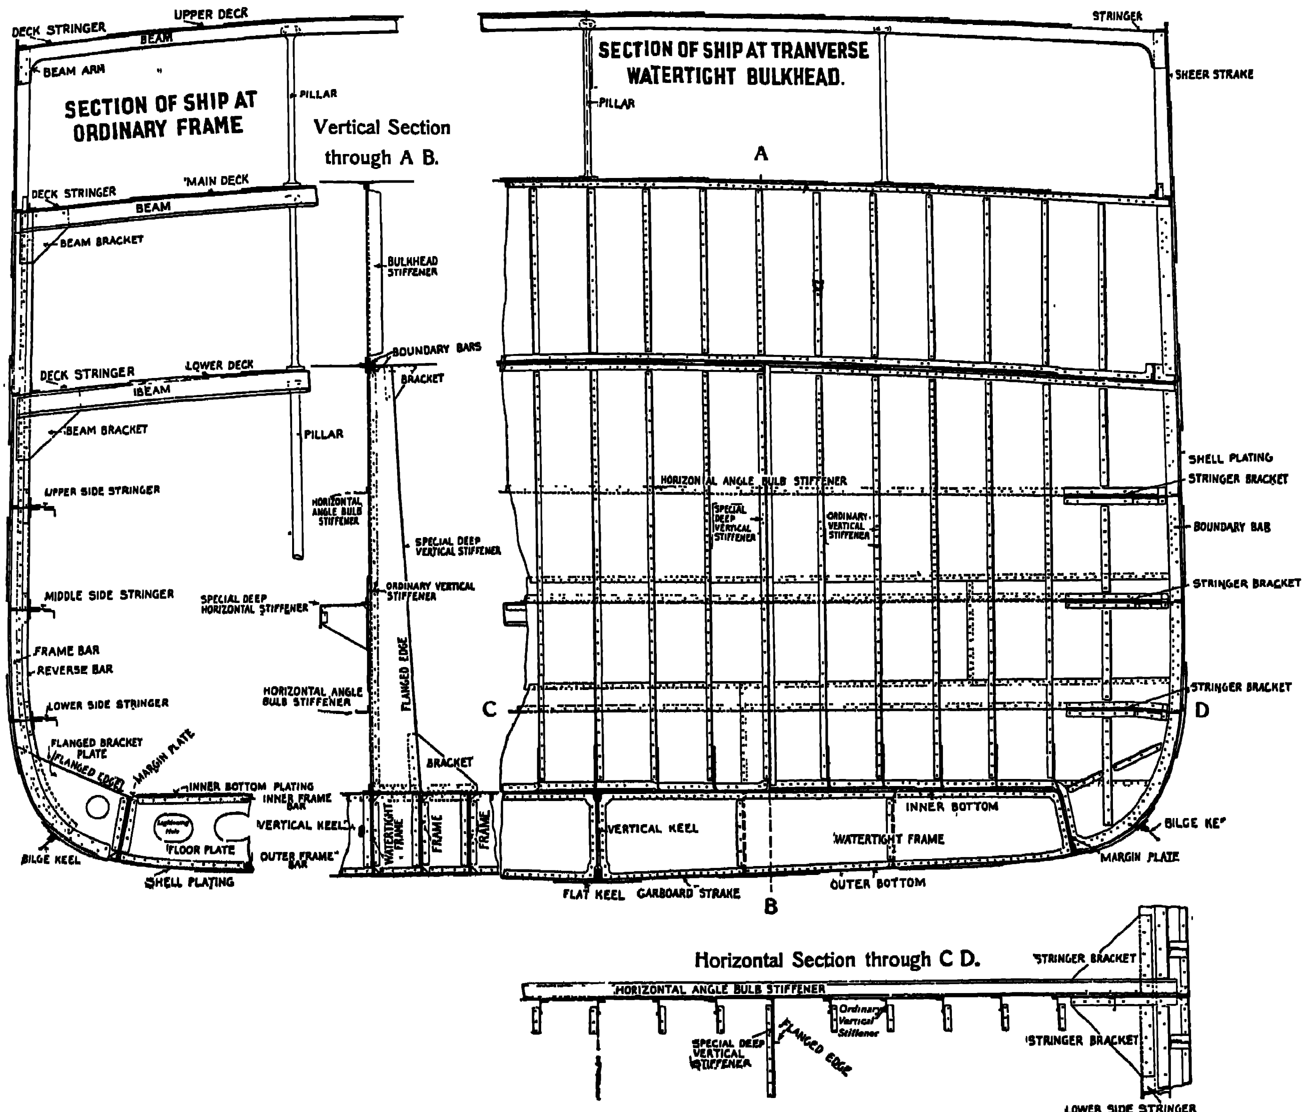

FIG. 21.—Details of framing and bulkheads.

Fig. 18 shows the construction of a typical American Lake steamer. a diagram of which is given in the article SHIP, Fig. 12.

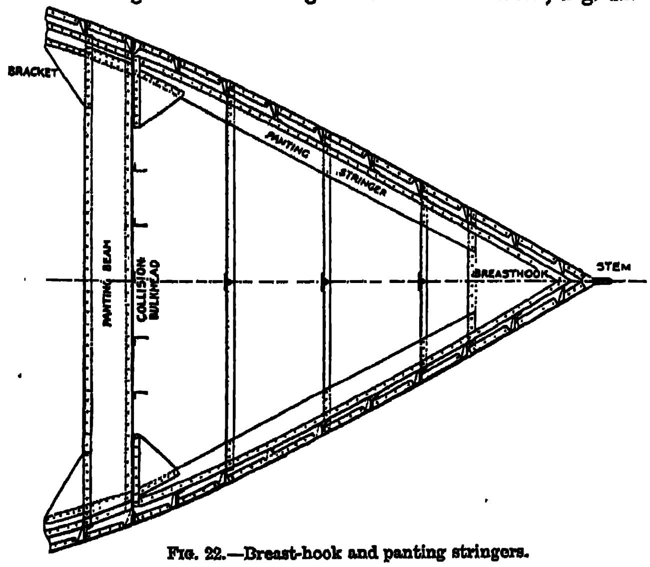

FIG. 22.—Breast-hook and panting stringers.

She is 450 feet over all, 50 feet beam, and 28 feet 6 inches moulded depth; and when loaded to a draught of 18 feet 3 inches can carry about 6000 tons weight of cargo on a total displacement of about 9000 tons. For half the length or more the ship is of the same transverse section, the frames being made identical in form. The outside plating is about $\frac{5}{8}$ inch thick generally, but it is thicker at the garboards, flat keel, and sheer strake, and becomes thinner generally towards the ends of the vessel. The frames are 24 inches apart, and consist of four separate pieces—two across the bottom and one up each side. Those across the bottom consist of a 15-inch channel bar, with deep flanged brackets of $17\frac{1}{2}$ ℔ plating connecting their inner ends to the centre keelson and their outer ends to the bilge and tank top. Extending up each side, the frames consist of 6-inch channel bars of 17 ℔ per foot, worked 24 inches apart in the case of ordinary frames; and 15-inch channel bars of 33 ℔ per foot, worked 8 feet apart, and called belt or special frames. The frames are all connected to the tank top and to the upper deck-plating by flanged bracket plates $17\frac{1}{2}$ ℔ per square foot; and the belt frames are stiffened by hold beams of I section, 12 inches deep and 35 ℔ per foot, attached to each by deep flanged brackets of $17\frac{1}{2}$ ℔ plating as indicated, and supported in the middle by stanchions or pillars of similar section. The stanchions are attached to the tank top by double clips of 6-inch angle bar, and to the upper deck beams by direct riveting and by flanged brackets of 15 ℔ plating. Each belt frame is thus complete in itself, and very readily erected after the tank top is completed. The tank top is of 20 ℔ plating amidships and under the loading hatches, and $17\frac{1}{2}$ ℔ elsewhere. The margin plate is a continuation of the tank top, is made of $17\frac{1}{2}$ ℔ plating, and flanged against the shell. The centre keelson is of about $22\frac{1}{2}$ ℔ plating and about $5\frac{1}{2}$ feet deep; the side keelsons are of $17\frac{1}{2}$ ℔ and slightly less depth, so that with a small rise of floor on the outside, say 3 inches in the half-breadth of the ship, there is a small fall of the tank top towards the bilges, say 6

American Great Lake steamer.

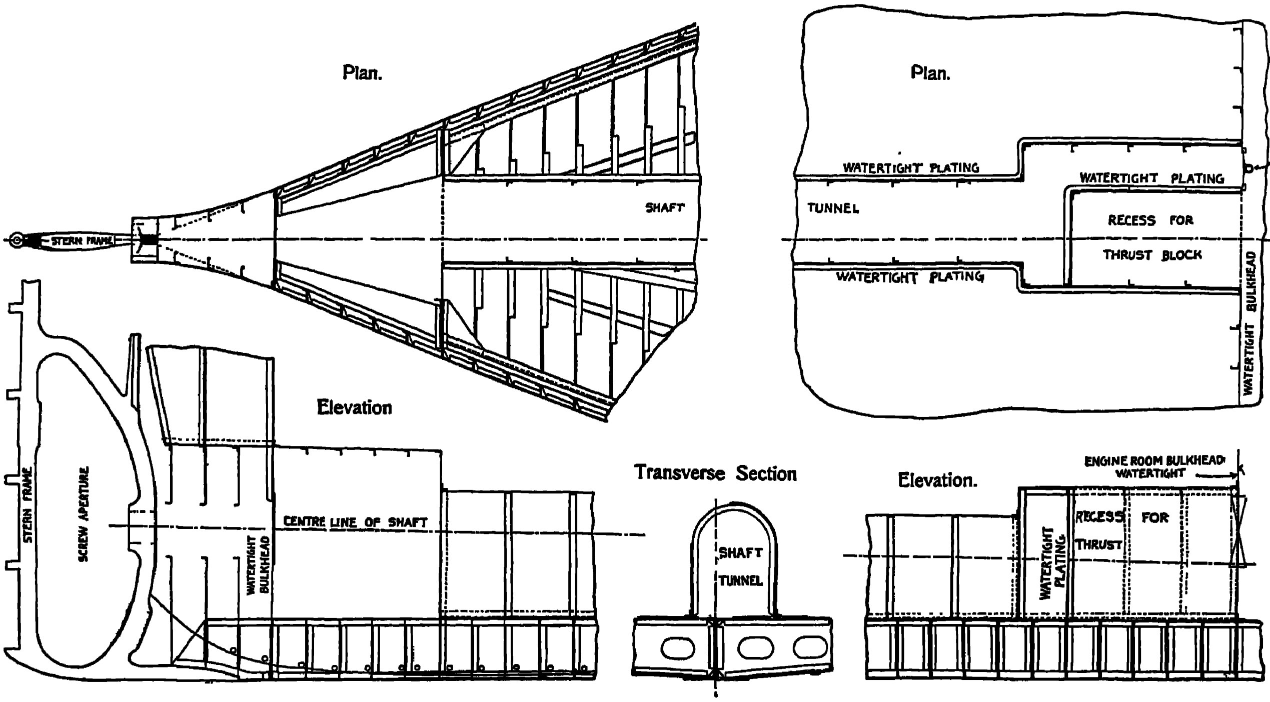

FIG. 23.—Stern framing, shaft tunnel, &c. of single-screw ship.

inches in the half-breadth, so as to drain the hold to the watercourses over the margin plates. The centre keelson extends from the inner to the outer bottom, being attached to the tank top and the flat keel by heavy double angle bars, and well stiffened by the flanged floor brackets, which are connected to it by heavy double angle bars. The side keelsons are connected to the tank top and the floors by fore-and-aft angle bars 3 inches by 3 inches of $7\frac{1}{2}$ lb per foot, and stiffened by vertical 6-inch angle bars at every frame. At the lower edge the keelson plates are connected to fore-and-aft intercostal channel bars 15 inches deep of 33 lb per foot, riveted to the shell-plating, which, with the channel floors, give very great local support to the bottom. This system of framing extends practically throughout the length of the vessel; thus the bottom is very strong, and very large ballast tanks are formed, having a capacity of nearly 3000 tons. The upper deck is plated, and the stringers are made specially heavy, to compensate for the strength lost by cutting wide hatchways.

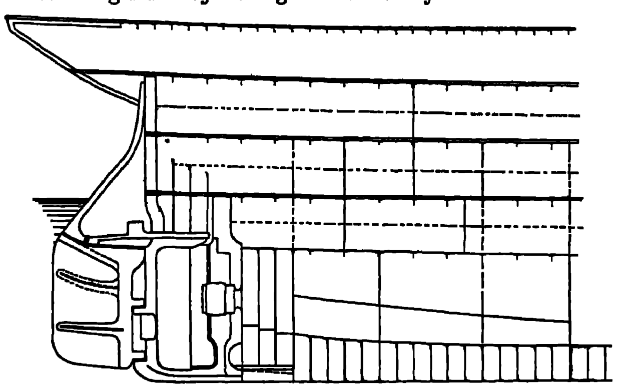

FIG. 24.—Stern framing of the *Campania*.

British cargo steamer.

Fig. 19 represents a modern British cargo steamer of ordinary construction, of about the same breadth and depth as the American Lake steamer just described, and it will be interesting to note the differences between the two vessels. These differences, so far as the outside form is concerned, are chiefly that the British cargo steamer has deck erections, topsides, and a main deck, whereas the Lake steamer has scarcely any deck erections and no topsides, while her hold extends from the top of the inner bottom to the upper deck; they are due to the fact that the latter ship is only required to traverse inland waters, where heavy weather is not met with, whereas the former is an ocean-going vessel, and must be prepared to meet all conditions of wind and sea. As to the differences in the details of construction, they are chiefly that in the American Lake steamer the bottom framing, which is of great depth, consists of deep channel-frame bars, above which the longitudinals are continuous, instead of the usual transverse framing in the British ship, extending between the outer bottom and tank top; and that the margin plate continues the surface of the tank top out to the side, instead of being nearly vertical, as in the British ship. The system adopted in the American steamer conduces to security in case of grounding in the shallow waters through which she has to pass.

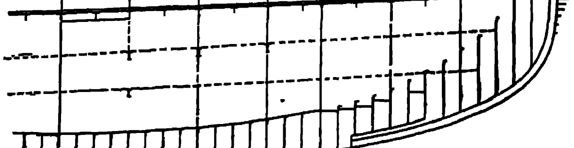

FIG. 25.—Bow framing of the *Campania*.

Atlantic liner.

The general construction of a large passenger vessel is shown by Fig. 20, which gives a perspective sectional view of the framing, &c., of the Cunard liner *Campania*. The transverse frames and the girders or longitudinals extend in depth from the outer bottom plating to the inner bottom plating. The centre keelson, the second longitudinal from the middle line, and the margin plate on each side, are continuous, the transverse frames being fitted between them and attached to them by angle bars. The first and third longitudinals from the middle line are intercostal, being fitted in short pieces between the frames and attached to the floor-plates by short angle bars. The floor-plates have large holes cut in them to lighten them, and to give access to the different spaces for inspection, painting, &c., and smaller holes for watercourses. From the margin plate the transverse frames consist of stout channel bars extending to the upper deck; each tier of beams is securely riveted to them, and their lower ends are connected to the margin plate by strong brackets. At intervals the channel-bar frames are replaced by deep built-up frames, the frequency of which depends on local requirements. Heavy side stringers of the same depth as the deep frames run fore and aft,

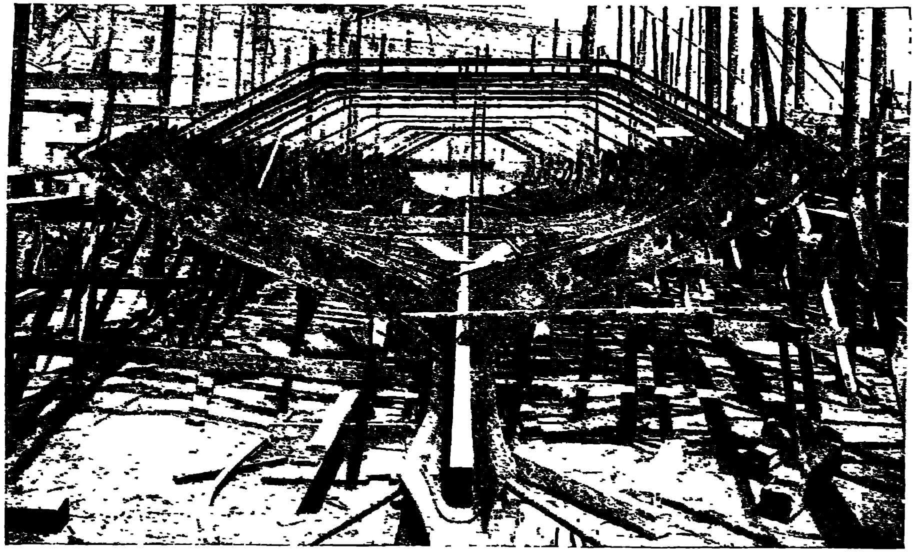

Fig. 26.

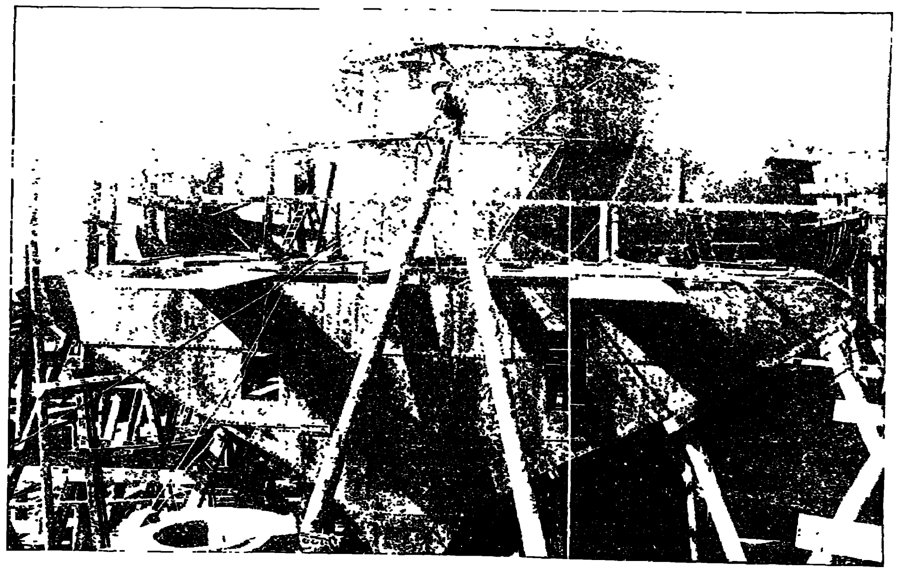

Fig. 29.

Stages in the Construction of a Warship

(*Japanese Cruiser "Idzumo."*)

to stiffen the side between the bilges and the first plated deck. Where the deep frames are cut by these stringers, the strength of the frames is continued by *gusset* plates, as shown.

Some further structural arrangements usually adopted in British ships are shown in Figs. 21 to 23. Fig. 21, to which reference has already been made, shows in detail the construction of a bulkhead, with the framing in wake of it, and the same details at an ordinary frame; also the stringers, beams, pillars, &c. The bulkhead itself stops at the tank top, being secured to it by double angle bars, and the floor immediately beneath it is made water-tight. It would involve very costly work to make the bulkhead water-tight if the side and bilge stringers were made continuous; these have therefore been cut, and the continuity of the longitudinal strength is maintained, as far as possible, by the large brackets shown in the plan. Besides bulb stiffeners, the bulkhead is provided with built-up vertical stiffeners at AB and a built-up horizontal stiffener at CD. Fig. 22 shows the arrangement for special strengthening at the extreme fore end of a vessel, between the collision bulkhead and the stem, and below the main deck, these consisting chiefly of panting stringers, panting beams, and breast hook. Fig. 23 shows the general arrangement of stern framing of a single-screw ship, including the shaft tunnel. A water-tight door, which can be closed when necessary from above the level of the outside water, shuts off communication between the engine-room and tunnel; the form of the stern post and aperture frame casting is shown, with its attachment to the centre keelson and other details.

Figs. 24 and 25 show the arrangements of the stern and bow framing of the *Campania*, which may be taken as those usually adopted in large passenger steamers of this class.[1] In both the transverse framing becomes deeper and stronger as the extremities are approached, while the decks and side stringers are all continued to the extremities, finishing in strong breast-hooks, and additional stringers, breast-hooks, and panting beams are introduced. It is worthy of note that the rudder and steering gear are in this vessel entirely under water, so that she may be used for war purposes without running the risk of disablement by the rudder or steering gear being struck by projectiles. Above the water the stern is finished off so as to have the appearance of being fitted with an ordinary rudder. This important departure from the usual practice was first introduced by Professor Biles in the *City of Paris*, and the *Campania* and her sister the *Lucania* were in 1902 the only British ships so fitted.

Fig. 30 gives in perspective the general structural arrangements of the Japanese cruiser *Idzumo*, and Figs. 26–29 (Plate II.) are from photographs of the vessel in course of construction. It will be seen that the departures from the structural arrangements of a merchant ship are very considerable. As already pointed out, lighter scantlings are used in warships than in ordinary merchant ships. This is effected by more carefully devised and more costly arrangements of framing and plating, and by making the structural features necessary in a warship for protection, &c., serve also for local and general strength. In warships, frames are placed at greater distances apart, 4 feet amidships and 3 feet at the extremities being the usual spacing, as compared with some 2 feet in a merchant ship. On the other hand, there are more continuous longitudinals in the framing of a warship, which extend in depth from the inner bottom to the shell-plating, and give local support to the bottom as well as general strength to the vessel. There are in a warship so many structural features, such as water-tight bulkheads and flats or platforms, required for the necessary subdivision, armour decks, plating and framing behind armour, &c., which are made to contribute to the strength of the structure as a whole, that the strength of the shell-plating and the transverse framing can be proportionately reduced.

Differences between war and merchant ships.

In a merchant ship there are many considerations which require the structure to be stronger and heavier than would be necessary to withstand the wind and waves which she may encounter. The continual change of cargo and of disposition of cargo necessitates special local strength throughout. The custom, often pursued, of grounding vessels to discharge cargo, and their liability to touch the ground in the ports they frequent, make the provision of great strength in the floors and the shell-plating essential. Other considerations affect the decks, and call for local strength in them with corresponding increase of weight.

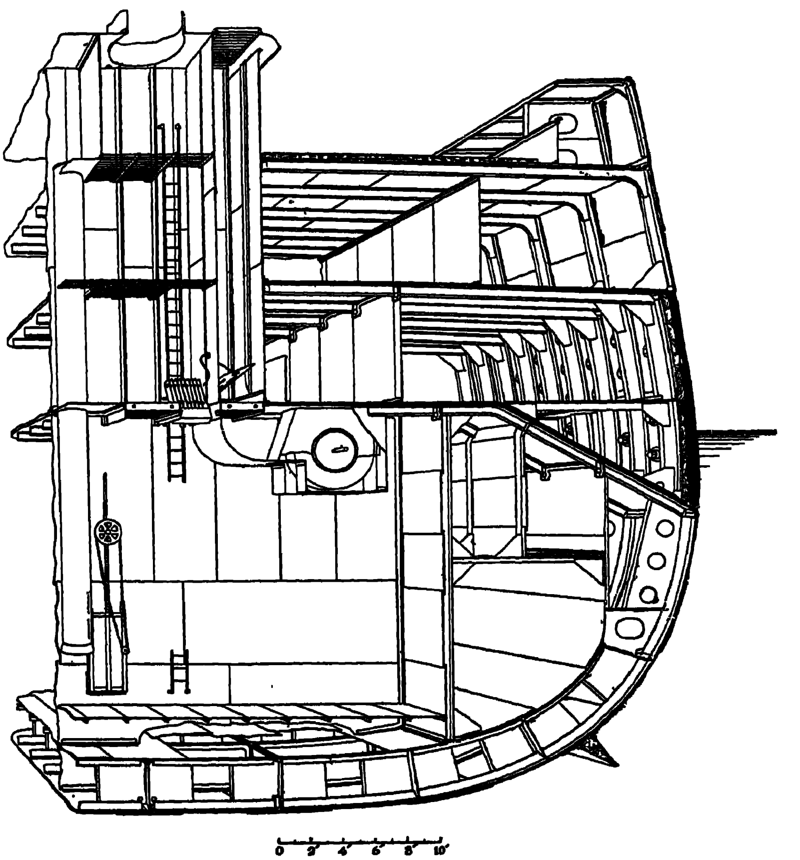

FIG. 30.—Japanese cruiser *Idzumo*; midship portion, in perspective.

Most warships, except gunboat, torpedo, and other small craft, have double bottoms, chiefly for protection against damage in action, but also against accidental grounding. The space between the bottoms is divided into a large number of compartments by making some of the frames and longitudinals water-tight. The inner bottom extends on each side to the turn of the bilge, and from that point is carried up vertically as a wing bulkhead, as shown in Fig. 28, the wing spaces thus formed being occasionally utilized for coal-bunkers. The framing, consisting of frame bars, reverse frame bars, and frame plates or brackets, is usually carried up in a fair curve to the armour shelf, supposing the vessel to be an armour-clad, as in Fig. 30. From the edge of the armour, which is generally about 5 feet below the load water-line, a change in structure is made, and the framing behind the armour is set back from the outside of the ship sufficiently to admit of an internal

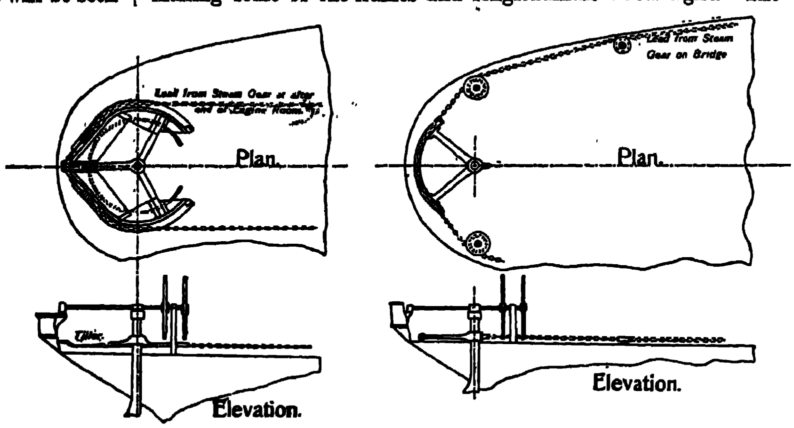

FIG. 31.—Steering-gear of merchant ship.

[1] We are indebted to Dr Elgar, F.R.S., for these and other plans of the *Campania*.

skin of steel plating (often worked in two thicknesses), teak backing, upon which the armour is embedded, and the armour itself, to be carried with the surface of the armour flush with the shell-plating. The vertical frames behind armour are spaced 2 feet apart, and the longitudinals are made intercostal, the whole having exceptional strength, to support the armour. Above the armour another change is made, the frames being brought again to the outside of the ship, and the topside plating directly attached to them becoming flush with the outside of the armour. There is generally a strong deck, called the protective deck, extending from stem to stern in the form of a turtle back, the lower edges being at the armour shelf on each side of the ship, and the top of the arch forming the first deck above water, as indicated in Fig. 28. With a view to maintaining its defensive power where it has to be perforated for funnels and air shafts, armour gratings, or armour bars as they are called, are fitted in the openings. As much water-tight subdivision as possible is introduced throughout the ship, but for communication between the various compartments openings are provided in the bulkheads, having water-tight doors which can be closed either from a position close to the door or from a deck above water, or from both. Below the protective deck are the engine and boiler spaces, magazines, shell-rooms, submerged torpedo rooms, and steering-gear. A passage is provided on each side of the ship just below the protective deck, for the supply of ammunition to the secondary armament.

Fig. 26 shows the *Idzumo* partially in frame, looking forward from the after extremity: the frames below the armour deck over a considerable length of the ship are complete, and a number of the beams which carry the armour deck are in place. Fig. 27 shows the ram stem, which has just been placed in position. The collision bulkhead and the framing below the armour deck are for the most part in place. Fig. 28 gives the top of the armour deck, which is nearly completed, as seen from the fore end, with the forward citadel bulkhead in course of construction. Fig. 29 shows the after part of the vessel, which is not so far advanced as the forward portion shown in Fig. 28. In Fig. 29 the framing has been carried to a bulkhead near the after extremity, the rudder post is in place, and the bearing for the rudder head can be seen in the foreground. The construction of the armour deck is proceeding, and the after citadel bulkhead is also well advanced, though no backing is yet upon it, as in the case of the forward bulkhead, but the base of the redoubt which carries the after turret is erected.

Internal fittings.

The whole of a ship's fittings are prepared during the building. The various plans are carefully worked out in the drawing-office, sketches being prepared to show the accommodation for passengers and crew, the rigging, bridges, and wheelhouse, the pumping and draining arrangements, steam piping and heating, details of steering-gear, anchor and cable gear and electric lighting, and of all blacksmiths', joiners', and shipwrights' work, upholstery, &c. Such drawings as are necessary are issued to all the various trades for guidance in performing their parts of the work; others are issued to manufacturers for the supply of completed fittings and special appliances, so that all may be ready at the proper moment for installation in place on board the vessel. In war vessels similar but more elaborate plans are required than in merchant ships, and, in addition, plans of magazine and shell room arrangements, gun foundations, torpedo installation, armour plates and bolts, transport of ammunition, and many others. The shares contributed by the various trades in completing the vessel are briefly as follows:—The shipwrights do all the heavier woodwork, such as laying decks, fitting ceilings, erecting and fitting storerooms, and completing all weather work. In the Royal dockyards their work embraces the fitting of the pumping, flooding, draining, and ventilating arrangements throughout the ship, part of the steering-gear, the greater part of the hydraulic mechanism, the supporting structures of the heavy guns, and much other work which is usually performed by fitters in private yards. The joiners do the more highly finished woodwork, such as cabin and saloon fittings and the lighter store-room fittings. Blacksmiths complete all the forged work, pillars, handrails, davits, mast fittings, awning stanchions, and a large variety of deck fittings. Fitters make and fit the water-tight doors, sluice, drain, and flood valves, gun-mountings and torpedo gear, and fit the steam windlass, winches, parts of the steering-gear, &c.

The fittings in a ship cannot be fully described in the present article, but we shall conclude with some account of the auxiliary machinery. Two ordinary arrangements of steering-gear fitted in merchant steamers are shown in Fig. 31. In the first example a three-quarter circular grooved rim, keyed to the rudder head, carries the steering-chains, which are led forward one on each side of the hatches to the steam engine, placed in this case in the engine-room casing, and controlled by shafting from the bridge. The usual steering-wheel is fitted on the bridge, and actuates the controlling valve of the steam engine by means of the shafting. The second example is very similar to the first: a quadrant is keyed on the rudder head, and worked by chains led over pulleys one on each side of the ship to the steam gear, which in this case is placed on the bridge, close to the wheel. In all such cases gear is also provided by which in an emergency the ship can be steered by hand, by steering-wheels placed close to the rudder head, as indicated in the figures.

Auxiliary machinery.

In a warship the arrangement is different, as it is necessary to keep the steering-gear below the water-line for protection. The breadth available at the rudder head is as a rule not sufficient for a tiller or quadrant to be fitted. Fig. 32 illustrates an arrangement frequently adopted. A crosshead of sufficient size is keyed on to the rudder head, and is worked by connecting rods from a similar crosshead placed a little farther forward, where the breadth of the ship is sufficient to allow a tiller to be worked. The tiller is worked

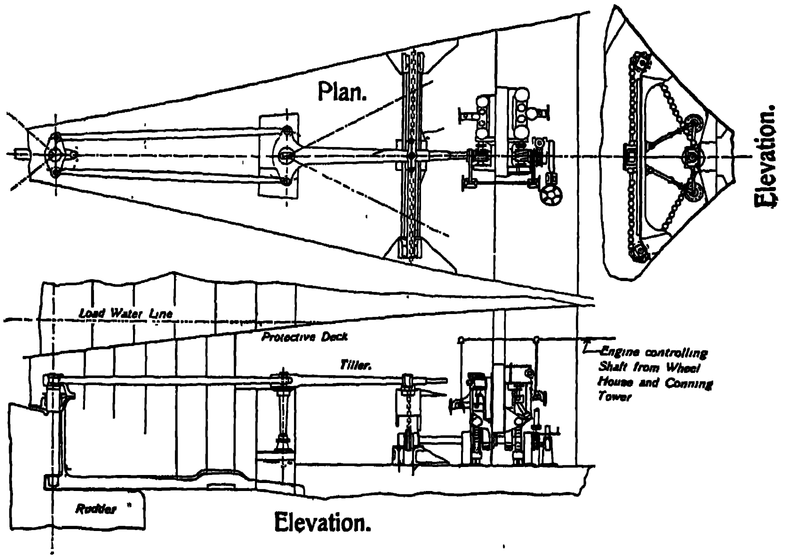

FIG. 32.—Steering-gear of warship.

by a block or carriage, which is drawn across the ship on a guide, at the same time sliding upon the tiller, which is machined for the purpose. The block-and-guide arrangement is known as Rapson's slide. The block is hauled to and fro across the ship by a chain which passes round a sprocket wheel upon a shaft, which is driven in either direction, as required, by the steering-engine. In many cases the steam steering-engine is placed in the engine-room, to avoid heating the after compartments by the steam pipes, and for the sake of easier control by the engineers.

Amongst the auxiliary machinery usually fitted in passenger and other well-found vessels may be mentioned the windlass for working the cables and weighing the anchors; a warping capstan forward in connexion with the windlass, and another aft with its own engine; steam winches for handling the cargo and baggage, and for hoisting coals on board; and occasionally steam cranes, fitted either in addition to or in place of the winches. Then there are the electric light, pumping, ventilating, and refrigerating installations. Hydraulic power is employed in many cases, especially for cranes, but here the source of the power is necessarily a steam engine, which is usually placed in the main engine-room. Electric power sometimes replaces steam for operating some of the machines enumerated above; for instance, ventilating fans are now generally driven by electric motors in passenger and war ships. A large number of comparatively small fans are used, each supplying air to a particular part of the ship. In warships the amount of auxiliary machinery has been very much increased in recent years. On each side of the deck amidships there is generally a steam winch for raising and lowering the boats, one of the principal functions of the mast in the modern warship being to carry the derrick used for this purpose. Electric motors are fitted for working the after-capstans, ash hoists, sometimes the winches, and the workshop machinery; also to traverse, elevate, and work the guns, and bring the powder and projectiles up from the magazines to the guns. But for the heavier guns, the steering-gear, and certain other purposes, hydraulic power or steam is still preferred. (P. WA.)

Ship Canals. See CANALS.

Shipley, a township in the Shipley parliamentary division of Yorkshire, England, on the Aire, 3 miles north by west of Bradford by rail. The parish includes the village of Saltaire, so named after its founder, Sir Titus Salt, who here established large alpaca manufactures. Area of urban district, 2179 acres. Population (1891), 23,387; (1901), 25,570.

Shippard, Sir Sidney Godolphin Alexander (1838–1902), British colonial administrator, was born in 1838, being the eldest son of Captain William Shippard, 29th Regiment. He was educated at King's College School, and went thence to Oxford, where he obtained an exhibition at Oriel College, and subsequently a scholarship at Hertford College. Taking his degree in 1863, he was called to the bar as a member of the Inner Temple in 1867. He then entered upon a long and honourable career in South Africa. In 1873 he was appointed Attorney-General of Griqualand West, a post which he continued to hold until 1877, when he was made Acting Recorder of the High Court of Griqualand. From 1880 to 1885 he sat as a judge of the Supreme Court of Cape Colony; and he was British Commissioner on the Anglo-German Commission in 1884–85 for settling the Angra Pequena and West Coast claims. It is, however, with Bechuanaland that his name is chiefly associated. He held the chief official position there from 1885 to 1895, being administrator, chief magistrate, and president of the Land Commission for British Bechuanaland, and resident commissioner for the Bechuanaland Protectorate and the Kalahari. In 1887 he was made K.C.M.G. In Bechuanaland the crucial problem of native administration was the liquor question. Khama, the great chief of the Bamangwato, addressed to Shippard in 1888 an appeal in which he said: "To fight against drink is to fight against demons, and not against men. I dread the white man's drink more than all the assegais of the Matabele, which kill men's bodies, and it is quickly over; but drink puts evil into men, and destroys both their souls and their bodies for ever. Its wounds never heal." Shippard took the same view, and the law prohibiting the supply of liquor to the natives was most strictly enforced by him, the result being that the natives became prosperous, happy, and peaceable. In 1896 Sir Sidney Shippard played a not inconsiderable, though unofficial, part in the negotiations between Sir Hercules Robinson, the High Commissioner, and the Johannesburg reformers after the Jameson Raid. On 7th January, in company with Sir Jacobus de Wet, the British Agent, Shippard made a most effective speech at the Johannesburg Club, which had considerable influence in inducing the Johannesburgers to lay down their arms. Sir Sidney Shippard was twice married, first to Maria, daughter of Sir Andries Stockenström, who died in 1870, secondly to Rosalind, daughter of Mr W. A. Sanford, of Nynehead Court, Wellington. He died on 29th March 1902.

Shipping Companies. See Steam-ship Lines.

Shirley. See Southampton.

Shirwa, Chirwa, or more properly Chilwa, a shallow lake in British East Africa, cut by 35° 20′ E. and lying between 15° and 15° 35′ S. The lake has greatly diminished in area within recent years, the open water filling less than half its former bed except in the rainy season, when the level plain round its margin is flooded. Formerly the water seems to have found an outlet northwards to the Lujenda branch of the Rovuma, but with the sinking of its level it is now separated from the latter by a wooded ridge some 30 to 40 feet above the surrounding plains. The permanent water, which is often almost unapproachable by reason of the swampy nature of its shores, measures only some 38 miles by 14, the width between the former elevated banks being about 20. There are four islands, the largest rising 500 feet above the water.

Shklov (Polish, *Szkłow*), a district town of Russia, in the government of Moghilev, on the highway to St Petersburg, and on the left bank of the Dnieper, 38 miles from Orsha railway station. It carries on an active trade in agricultural produce and manufactured goods imported from Austria. Population (1897), 10,630.

Shoa. See Abyssinia.

Sholapur, a city and district of British India, in the Deccan division of Bombay. The city is 164 miles south-east from Poona by rail. Municipal area, about 8 square miles; population (1881), 61,281; (1891), 61,915; (1901), 74,521. Since 1877 it has ceased to be a military cantonment. The large bazaar is divided into seven sections, one of which is used on each day of the week. There are two municipal gardens, with fine tanks and temples. A cotton mill, with 400 looms and 36,000 spindles, employs 1500 hands. The high school had 339 pupils in 1896–97. There are six printing-presses, each issuing a vernacular newspaper.

The district of Sholapur has an area of 4542 square miles; population (1881), 583,411; (1891), 750,689, showing an increase of 29 per cent. after the famine of 1876–77; average density, 165 persons per square mile. In 1901 the population was 720,978, showing a decrease of 4 per cent. The land revenue and rates are Rs.13,49,501, the incidence of assessment being just over 8 annas per acre; cultivated area (1897–98), 1,948,084 acres, of which 105,677 were irrigated from wells, &c., including 9145 from Government canals; number of police, 588; children at school (1897–98), 9710, being 1·3 per cent. of the total population; registered death-rate (1897), 44·81 per thousand. The principal crops are millet, oil seeds, and pulse. The Ekruk tank, near Sholapur city, is the second largest irrigation work in the Deccan. The capital outlay has been Rs.13,40,000. In 1897–98 the gross receipts were Rs.16,883, and the expenditure Rs.33,730, showing a loss of Rs.16,847. There are manufactures of silk and cotton cloth, and blankets. The chief trading mart is Barsi, in a tract surrounded by the Nizam's dominions, with 8 factories for ginning and pressing cotton. Pandharpur is a popular place of pilgrimage. The Great Indian Peninsula Railway runs through the district for 115 miles, with a junction for the Southern Mahratta railway (8 miles), and another junction for the Barsi light railway (22 miles), now being extended to Pandharpur (30 miles).

Shooting.—The taste for sport of all descriptions has developed so rapidly in modern times that, as regards shooting alone, for one person who handled a gun fifty years ago, probably twenty do so now, while the head of game reared and preserved for sporting in the United Kingdom had increased at least 50 per cent. during the same period. As a consequence, the art of gunmaking has improved in proportion, and in view of the modern hammerless ejector gun, with its choke-bore, single-trigger, snap-action, and nitro-powder cartridges, it seems impossible to believe that in the middle of the 19th century sportsmen were still using muzzle-loaders and black powder. None the less it is open to discussion whether modern guns and powders can claim any extraordinary superiority of killing power: their supremacy lies in the case with which they can be loaded and fired, and, in the case of powders, in the absence of recoil and smoke.

For all practical purposes a 12-bore gun, weighing about 6¾ lb with 30-inch barrels, is the most useful for sportsmen of average physical capacity; lesser gauges can only be recommended for the aged or constitutionally infirm. Too great care cannot be exercised in the choice of such a weapon, and, despite the considerable initial expense, it will eventually prove an economy for the intending purchaser to place himself in the hands of a firm of London gunmakers of repute, and pay a good price for a good

article. Such a gun will practically last a lifetime, while the care bestowed on its "fit" and finish proves a source of increased skill in shooting, and of consequent satisfaction to its owner. From this, however, it must not be supposed that there are not many excellent provincial gunmakers, nor that the price of a gun is an invariable proof of its excellence. A really first-class London-made, fitted, and proved gun should be obtained for £40 or £45, and a pair for from 90 to 100 guineas; though these prices are of course susceptible of considerable modification or increase. Single-trigger guns, the latest fashion, are not specially desirable, nor is excessive choking to be recommended. A pattern of 140 for the right and of 160 for the left barrel is ample for ordinary game shooting, while a load of 40 to 42 grains of nitro-powder, with 1 or $1\frac{1}{4}$ oz. of No. 5 or 6 shot, is sufficient for general purposes.

Although many varieties of game and wild-fowl exist in the United Kingdom, it is not within the scope of the present article to do more than merely touch on the shooting of those most commonly met with. Foremost among them must be placed the grouse, and it is hard to say whether grouse-shooting over dogs or grouse-driving be the more enjoyable form of sport. Until recent years the latter form of grouse-shooting was almost entirely confined to the English moors, but it is now very generally practised in Scotland as well; though here, in the writer's opinion, it has not proved an unqualified success, at all events in the Highlands. The main advantage claimed for grouse-driving is that, by killing off the old birds which usually come first to the guns, the younger and healthier birds are left as a breeding stock, and on the English and Lowland Scottish moors, which are naturally adapted to driving, this has produced the most astonishing results. But in the rugged and mountainous Highland districts it is not possible properly to work the "tops" and summits, which are the strongholds of the noxious old cocks it is so desirable to exterminate, and consequently—with some notable exceptions—driving has but too often had a retrogressive effect. The best proof of this is a comparison of the bags obtained in the Highlands a generation ago, when driving was not practised, with those of the present day. In laying out a moor for grouse-driving, special attention should be paid to its configuration, and to the probable flight of the birds, which as a rule always follow the depressions and "slacks" in its surface. Where possible, the "butts" should always be placed in a hollow of the ground; this not only helps to conceal them from the birds, but also produces higher and prettier shots. Very long drives are to be deprecated; moderately short ones, where the birds can be kept constantly moving, and sent backwards and forwards over the same line of butts, will be found the most effective, as by this means the coveys get broken up. In grouse-driving, where birds are fairly plentiful, the sportsman should never turn to fire at those which have passed him; he will kill four birds in front of his butt for every one behind it. He should not crouch in his butt nor seek to conceal himself by stooping, but remain perfectly motionless, until the moment when he throws his gun up to his shoulder to fire. Above all, he should not reserve his fire until the birds are close upon him—a very common mistake among tyros in grouse driving, which considerably lessens the probability of killing the grouse, and which moreover leads to a cramped and "poking" style of shooting. It is a good plan before the beginning of a drive to mark some object about 40 yards in front of one's butt—a white stone or a prominent tuft of heather—and to open fire as soon as the grouse have come within that range. Grouse-shooting over dogs is a fine sport where grouse can be found to lie to them, but its main features are so well known and its methods so simple that it hardly merits further description. Two rules, obvious, but frequently ignored, should be borne in mind—during the heat of the day grouse will generally be found near water, and in wild stormy weather they should be sought on the lower slopes, and not on high ground. Large, big-boned setters are the best dogs for grouse-shooting; small, light-framed animals are unable to bear the heavy work, and pointers are more easily affected by the cold, damp climate of the Highlands.

It is commonly but erroneously presumed that partridge-shooting over dogs is a thing of the past, but there are still many parts of Great Britain where the use of dogs—preferably pointers—is not only customary, but essential to success. Nor can the present wildness of partridges be ascribed, as it so often is, to the short stubbles left by the modern reaping-machine; grouse have become equally wild of late years, and the reaping-machine argument, which is quoted *ad nauseam*, can hardly be applied to them. Moreover, even if knee-deep stubbles—presuming them to have ever existed—have disappeared within the last half-century, root and clover crops, which afford far better cover, have increased in the proportion of two to one in the same period. The wariness of modern game must be attributed to its real cause—the enormous increase in shooters, and the corresponding improvements in firearms. The most general method of shooting partridges nowadays is to drive them off the stubble and grass fields into the root crops, and then walk them up in line—a rather uninteresting form of sport. Care should always be taken to walk across the drills; and when, as must frequently happen, a dead or wounded bird cannot be found at once, it is advisable not to waste time in looking for it at the moment, but to beat the field out, as otherwise any game still in front of the guns will run down the furrows and rise out of shot. A stick should be thrust into the ground where the bird was seen to fall, and it can be looked for afterwards; but the best plan, where practicable, is to have an attendant keeper with a couple of steady retrievers, whose sole business is to stay behind the line of guns to look for such lost or running birds. As with grouse so with partridges, the tendency of the age is to drive them where practicable, and of all forms of what may be termed "artificial" shooting, not one is so difficult of consummation as partridge-driving. To attempt it in an unsuitable locality without careful attention to the usual line of flight of the birds, or above all, under the direction of a keeper who does not understand the art of driving—and how many are there who do?—is merely to court disaster, and to spoil what otherwise might have been an excellent day's shooting "in line" or over dogs. But, given the necessary essentials to success, partridge-driving is a delightful sport, which, moreover, tends enormously to increase the stock of birds. To kill driven partridges neatly and consistently is the highest test of skill in shooting, requiring great quickness of hand and eye, and, it is needless to remark, considerable experience. Space only permits of mention of one axiom for success. The shooter should stand as far back as possible from the hedge behind which he is placed, and as the covey tops it, concentrate his attention on the bird which first catches his eye, and not allow it to be diverted to another. Wherever possible, the guns should stand in a grass field—where running or wounded birds are more easily retrieved—equidistant between two fields of roots, so that the birds, being gradually collected into the one, can be sent out of it over the guns into the other, and unless the ground or the wind be unfavourable, brought back again in a return drive; the more partridges are broken up and kept on the move, the better. Frequent change of blood is essential

where it is intended to maintain a large stock of partridges, and all superfluous cocks should be killed off before the commencement of the breeding season; this is easily done by an experienced keeper.

In dealing with pheasant-shooting, or, to give it its modern title, "covert-shooting," it is essential to point out that, except when treated as a "rocketer," the pheasant is an uninteresting bird of sport, which, unless forced to the contrary, invariably seeks to escape by running instead of flying. A rocketer is therefore an artificial production; it is made, not born, and it has been rightly described as a bird flying high and fast towards the shooter; but as such, if only it be high and fast enough, the pheasant has no superior from a shooting point of view. In order to ensure "rocketers," pheasants, if possible, should always be driven down hill; on flat ground, where this is not practicable, the guns should be placed at such a distance from the covert as enables the birds to rise high and get well on the wing before coming over them. In such localities, too, it will be found a good plan to cut away the undergrowth for a yard or two at the end of the covert to which the pheasants are driven; this generally has the effect of making them fly high. Where pheasants exist in any number, a "false covert" of spruce and fir loppings should be made at the point to which it is desirable to force the birds; they will collect in this, and can then be sent over the guns in small lots at a time. As in grouse and partridge driving, much of the success of a day's covert-shooting depends on the organizing skill of the head keeper and the manner in which he beats his coverts and places his "stops." With regard to ground game, owing to legislation, the days have long since passed when hares would form one of the chief accessories to a day's shooting. Whether this be advantageous from a national point of view it is not within the province of this article to discuss, but from a sportsman's point of view it is regrettable. Not, it must be confessed, that hares either afford great sport or demand much skill in shooting, but they form an agreeable addition to a bag, and supply an excellent article of food for the table. Rabbits, on the other hand, which are far more injurious animals to vegetation of every description, show no signs of extinction. Where they are found in large quantities, the most generally practised method of shooting is to ferret them out of their burrows, which are then filled in with soil or drenched with paraffin, to induce the rabbits to remain above ground, when they are walked up in line, affording most excellent sport. Where cover is scarce, brushwood and fir-loppings should be strewn about for them to shelter under. Rabbits will readily lie out under such conditions for two, or even three, nights, provided only the weather be dry, but in the event of snow or rain nothing will prevent them from going to ground again. First-rate sport is obtained during the summer months by stalking rabbits with a pea-rifle, but this should only be practised where there is no danger to live-stock or human beings from a stray or deflected bullet. Similar, but far finer, sport may be enjoyed by stalking black-cock, in districts where these beautiful birds are to be found.

Finally, with regard to the art of shooting. It is hardly necessary to point out that no amount of theoretical instruction can produce proficiency in this, and that only experience and constant practice can ensure success. But the young or inexperienced shooter should bear one golden rule in mind—that in firing at a moving object his purpose should be to place his charge of shot not where such object actually is at the moment of pulling the trigger, but where it will be by the time the shot reaches it; in other words, the game should fly, or run, into the shot. Moreover, he should train himself to effect this not by dwelling on his game with his gun at his shoulder—a clumsy and dangerous style of shooting—but by firing at an imaginary point in front of it. This of course is a knack only to be acquired by practice; but, paradoxical as it may seem, the man who wishes to acquire a quick and good style of shooting should refrain from aiming at—and consequently dwelling on—what he is trying to kill. Brain, eye, and hand must all operate in instantaneous sympathy, and the actions of throwing the gun up to the shoulder and discharging it should be almost simultaneous.

Rifle Shooting.—Of late years there has been a remarkable tendency towards the use of small-bore rifles both for military and sporting purposes, on account of their low trajectory, extraordinary velocity, and absence of recoil and report. For thin-skinned animals, such as antelope or deer, the ·256 Mannlicher, with a bullet specially prepared to expand on impact, is probably the most perfect weapon extant. But it must be borne in mind that small-bore rifles do not inflict the "shock" of the larger gauges and heavier loads; and although the largest and most dangerous game may be, and often is, killed by one of these tiny bullets, yet they are not to be relied on in those situations, occasionally inevitable in big game shooting, where the sportsman has to stop the charge of a dangerous and infuriated animal. Where such a possibility may occur, the use of a heavy rifle, a 10 or 12 bore, or a ·577 Express, is to be preferred; but gunmakers are now beginning to produce sporting rifles of moderate weight and gauge, ·400 and ·450 bores, for use on dangerous game, which fire cordite instead of black powder, the "smashing" powers of which are claimed to far exceed those of the old-fashioned large-bore rifles.

Among a score of useful works on shooting may be cited the volumes of the "Badminton Library" dealing with this subject; *Hints to Young Shooters*, by Sir R. PAYNE-GALLWEY; *The Fur and Feather* series, published by Messrs Longmans, Green and Company; and *Wild Beasts and their Ways*, by Sir SAMUEL BAKER. (P. ST.)

Shoreham, a town and urban district, England, Sussex, in the Lewes parliamentary division of the county, at the mouth of the river Adur, 5 miles east of Worthing, with a station at the junction of the Horsham branch of the London, Brighton, and South Coast Railway with its coast line. Formerly it returned two members to Parliament, but in 1885 its representation was merged in that of the county. The trade of the small port is chiefly in coals, corn, and timber. Shipbuilding is also carried on. It was from Shoreham that Charles II. escaped to Fécamp after the battle of Worcester, 1651. The population of the parish and urban district of New Shoreham was in 1891, 3393; in 1901, 3837.

Shorncliffe, a military station, Kent, England. See SANDGATE.

Shorthand.—The distinctive features in recent shorthand history have been the widely-extended employment of the art, the increased attention paid to instruction, and the growth of stenographic societies. Throughout the civilized world the systems employed are those of the leading authors of the 19th century; earlier systems have now a numerically small number of practitioners. Shorthand has become an almost indispensable qualification for the amanuensis, and practical stenographic ability is a necessary equipment of the typewriter operator. In professional and commercial offices, and more recently in the services, dictation to shorthand writers has become general. Shorthand has been included among examination subjects for the army, navy, civil service, and medicine in the United Kingdom, and to a certain extent in other countries. Its inclusion in the Technical Instruction Act of 1889 was the first recognition of shorthand by the British Parliament,

and it was subsequently comprised in the codes of elementary day and evening continuation schools. It first became an examination subject for secondary schools in the Oxford Local Examination in 1888, but the Society of Arts has examined students of polytechnics, &c., in shorthand since 1876. Examinations in connexion with the phonographic system of Isaac Pitman date from 1845.

In 1887 the tercentenary of the origination of modern shorthand by Timothy Bright and the jubilee of Isaac Pitman's phonography were celebrated by the holding of the first International Shorthand Congress in London. Subsequent congresses were held at Paris (1889), Munich (1890), when a statue of Gabelsberger was unveiled; Berlin (1891), Chicago (1893), Stockholm (1897), and Paris (1900). These gatherings have promoted the improved organization of stenographic practitioners in the respective countries. After the first congress, three national organizations were established in Great Britain by Pitman writers, which take the place of the Phonetic Society (established in 1843 and dissolved in 1895). In America the formation of national associations for reporters and teachers followed the fifth congress. The inventor of phonography, Sir Isaac Pitman (1813–97), was knighted three years before his death for his "great services to stenography." An enumeration made in 1894 showed that 95 per cent. of British newspaper reporters write Pitman's system. Recent essays in English shorthand authorship are almost entirely in the direction of script characters with connected vowels, as contrasted with the geometric forms and disjoined vowels of Pitman's phonography. The majority are founded on the French system of the brothers Duployé, but *Cursive Shorthand* (Cambridge, 1889), by Professor H. L. Callendar, and *Current Shorthand* (Oxford, 1892), by H. Sweet, LL.D., may be noted as original methods, the first having a phonetic, and the second both an orthographic and a phonetic, basis.

The earlier article on SHORTHAND in the *Encyclopædia Britannica* (xxi. 836) contains a full account of the subject. Among the later publications dealing fully with the history and practice of shorthand are the *Transactions* of the London Congress in 1887, and similar publications in connexion with later congresses; *Bibliography of Shorthand*, by J. WESTBY-GIBSON, LL.D. (London, 1887), treating of English, colonial, and American authors; *Shorthand Instruction and Practice*, by J. E. ROCKWELL, of the United States Bureau of Education (Washington, 1893), dealing with shorthand work throughout the world; and *Examen Critique des Sténographies Françaises et Étrangères*, by Dr THIERRY-MIEG (Versailles, 1900). For Sir Isaac Pitman see *Biography*, by T. A. REED (London, 1890); *History of Our Own Times*, vol. v., by JUSTIN M'CARTHY (1897); and *Dictionary of National Biography*, third supplementary volume (1901). An interesting discovery in shorthand biography may be noted, namely, that Samuel Taylor, the author of the system bearing his name, died in 1811; see M. LEVY in *The Times*, 10th April 1902, and *Notes and Queries*, 24th May 1902. (E. PI.)

Shorthouse, Joseph Henry (1834– ——), novelist, was born in Great Charles Street, Birmingham, 9th September 1834, eldest son of Joseph Shorthouse, chemical manufacturer, and Mary Ann, daughter of John Hawker, of the same town. He was educated at Grove House, Tottenham, where he proved a promising and industrious pupil, and upon leaving school entered his father's business, in which he was all his life actively engaged. He married, in 1857, Sarah, daughter of John Scott, of Birmingham. His literary interest was fostered by a local essay club, to which he contributed many papers. It was not until he was nearly fifty years old that Shorthouse made his public appearance as an author, and even then his remarkable story, *John Inglesant*, had undergone vicissitudes. It was kept for over three years in MS., and the author eventually printed one hundred copies for private circulation. One of these found its way into the hands of Mrs Humphry Ward, who recommended it to a publishing house. Its first appearance was a quiet one; but Gladstone was at once struck by its quality, and made its reputation by his praise. It became the most discussed book of the day, and its author was suddenly famous. Besides *John Inglesant* (1881), Mr Shorthouse published *The Little Schoolmaster Mark* (1883), *Sir Percival* (1886), *The Countess Eve* and *A Teacher of the Violin* (1888), and *Blanche, Lady Falaise* (1891); but none of these has been so popular as his first novel. He will always remain known to fame as "the author of *John Inglesant*." Mr Shorthouse was originally a Quaker, but the appeal of the Anglican Church was insistent with him, and he was baptized into its body before the appearance of his story. Something of his own stress of religious transition appears in the character of his hero, who is pictured as living in the time of the Civil War, a pupil of the Jesuits, a philosopher and a Platonist, who is yet true to the National Church. The story, which is deeply mystical and imaginative, has for its central idea the dangers of bigotry and superstition, and the necessity of intuitive religion to progress and culture. It is a work full of opulent colour and crowded life, no less than of philosophy and spiritual beauty. Mr Shorthouse's work is always marked by high earnestness of purpose, a rich and luxuriant manner, and a naturally religious spirituality. He lacks dramatic faculty and the workmanlike conduct of narrative, but he has almost every other quality of the born novelist.

Shoshong. See BECHUANALAND.

Shotts, a mining and manufacturing parish of Lanarkshire, Scotland, comprising five villages and parts of two others, and two stations on the North British and three on the Caledonian Railway. The parish contains large iron works, tile, fire-clay, and brick works, and quarries. There are four Established churches, three United Free, an Original Secession, a Congregational Union, and a Roman Catholic. Seven public schools had in 1898–99 an average attendance of 1399, and a Roman Catholic school 755. Population (1891), 11,957; (1901), 15,561.

Shreveport, a city of Louisiana, U.S.A., the capital of Caddo county. It is situated in 32° 30′ N. and 93° 45′ W., in the north-western part of the state, at an altitude of 180 feet. It has seven railways, the Queen and Crescent, the Houston and Shreveport, the Port Arthur Route, the St Louis South-Western, the Shreveport and Red River Valley, the Texas and Pacific, and the Sherman, Shreveport, and Southern. These, with boats on the river, which is navigable, give the city a large trade. The surrounding country is a rich agricultural region, mainly devoted to the production of cotton, for which Shreveport serves as the principal shipping point. It contains cotton gins, compresses, and oil mills. Population (1890), 11,979; (1900), 16,013, of whom 726 were foreign-born and 8542, or 53 per cent., were negroes.

Shrewsbury, a municipal and parliamentary borough, capital of Shropshire, England, in the Newport parliamentary division of the county, 30 miles south of Chester by rail. The wards of the municipal borough were rearranged in 1891. The church of St Mary's, much injured in 1894 by the fall of 50 feet of its spire, has been restored, and also the church of the Holy Cross, while that of Holy Trinity has been rebuilt with the exception of the chancel. The Shire Hall and Guildhall, burned down in 1881, were rebuilt in 1884 at a cost of over £30,000. The free library and museum installed in the old building of the grammar school were opened in 1885, and a new theatre was built in 1898. The Royal Grammar School

was removed in 1882 to Kingsland, on the Hereford side of the river, where a tract of 27 acres, formerly the scene of the Shrewsbury Show, had been acquired. The buildings of the old foundling hospital, originally costing £12,000, were adapted to the purposes of the school; other buildings were erected, including residences for masters; and a handsome school chapel, part of which forms a memorial to Dr Kennedy, headmaster, 1836–1866, was dedicated in 1883. In 1894 the Jubilee Baths were built. Population (1891), 26,967; (1901), 28,396.

Shropshire, or SALOP, a north-western county of England, on the borders of Wales, bounded on the N. by Cheshire and an interpolated portion of Flint, on the E. by Stafford, on the S.E. by Worcester, on the S. by Hereford, on the S.W. by Radnor, on the W. by Montgomery, and on the N.W. by Derby.

Area and Population.—The area of the ancient and administrative county, as given in the census returns of 1891, is 859,576 acres, or 1343 square miles, with a population in 1881 of 248,022, in 1891 of 236,339, of whom 116,736 were males and 119,603 females; and in 1901 of 239,321; the number of persons per square mile being 178, and of acres to a person 3·5. In 1895 the following changes were made in the area of the administrative county:—To Hereford was transferred the part of the parish of Lantwardine in Shropshire, to Stafford the part of the parish of Bobbington in Shropshire, to Worcester the parish of Dowles, and to Shropshire the parish of Tittenley from Cheshire, the part of the parish of Ludford in Hereford, and the part of the parish of Sheriff Hales in Stafford. The area of the registration county is 952,842 acres, with a population in 1891 of 254,765, of whom 84,549 were urban and 170,216 rural; and in 1901 of 259,093. Within the registration area there was between 1881 and 1891 a decrease in the population of 4·18 per cent. The excess of births over deaths between 1871 and 1881 was 29,072, but the decrease in population was 11,112. The following table gives the numbers of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1898:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Males.	Females.
1880	1500	7750	4619	339	281
1890	1612	6858	4442	283	235
1898	1772	6898	4055	254	240

The number of marriages in 1899 was 1779, of births 6718, and of deaths 4366.

The following table gives the marriage-, birth-, and death-rates per 1000 of the population, with the percentage of illegitimate births, for a series of years:—

	1870-79.	1880.	1880-89.	1890.	1888-97.	1898.
Marriage-rate	12·6	11·3	11·9	12·6	13·1	14·4
Birth-rate	31·8	29·1	28·7	26·8	27·6	28·0
Death-rate	19·1	17·3	17·4	17·4	17·2	16·5
Percentage of illegitimacy	8·6	8·0	8·2	7·6	7·4	7·2

The percentage of illegitimacy is exceptionally high for an English county. In 1891 there were in the county 797 natives of Scotland, 1284 natives of Ireland, and 2118 foreigners.

Constitution and Government.—Neither the parliamentary nor the judicial arrangements have undergone any change since 1886. There are six municipal boroughs: Bishop's Castle (1378), Bridgenorth (6049), Ludlow (4552), Oswestry (9579), Shrewsbury (28,396), and Wenlock (15,866). The following are urban districts: Church Stretton (816), Dawley (7522), Ellesmere (1945), Newport (3241), Oakengates (10,837), Wellington (6273), and Whitchurch (5219). The ancient county, which is in the dioceses of Hereford, Lichfield, and St Asaph, contains 261 ecclesiastical parishes and districts, and parts of 24 others.

Education.—Shrewsbury is the seat of a famous public school. The number of elementary schools in the county on 31st August 1899 was 310, of which 36 were board and 274 voluntary schools, the latter including 254 National Church of England schools, 5 Wesleyan, 7 Roman Catholic, and 8 "British and other." The average attendance at board schools was 6732, and at voluntary schools 28,030. The total school board receipts for the year ended 29th September 1899 were £23,806. The income under the Agricultural Rates Act was over £1010.

Agriculture.—About five-sixths of the total area is under cultivation, and of this area about five-eighths is in permanent pasture. There are also about 35,000 acres in hill pasturage, 4800 under orchards, and 50,000 under woods. The acreage under corn crops has been diminishing, the diminution being chiefly in the acreages under wheat and barley, oats tending rather to increase. About five-sixths of the acreage under green crops is occupied by turnips, cattle being largely kept specially for dairy purposes. The following table gives the acreages of the main divisions of the cultivated area at intervals from 1885:—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1885	716,599	150,085	61,101	71,470	426,859	6978
1890	720,431	143,678	58,696	70,946	441,553	5296
1895	717,963	131,809	57,076	69,526	455,521	3577
1900	719,080	132,590	55,044	71,149	458,027	1873

The following table gives the numbers of the principal live stock for the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1885	32,323	162,932	60,976	438,664	61,067
1890	32,683	166,660	60,669	479,880	74,025
1895	35,205	164,928	59,406	437,987	81,560
1900	33,736	180,113	63,604	470,577	66,594

Industries and Trade.—According to the report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 14,318, as compared with 13,706 in 1896. Woollen goods are manufactured. Non-textile factories employed 10,644 persons, there being an increase between 1895 and 1896 of 18·2 per cent., and between 1896 and 1897 of 1·2. Of these, 3201 were employed in the manufacture of machines, appliances, conveyances, tools, &c. (chiefly agricultural implements at Ludlow, Oswestry, Shrewsbury, Wellington, &c.), 2130 in the founding and conversion of metals, 2064 in the clay and stone industries (including earthen and china ware, bricks and tiles, encaustic tiles, and tobacco pipes in the Broseley district). Workshops employed 3014 persons, 1447 being employed in clothing industries. The total number of persons employed in connexion with mines and quarries in 1899 was 5487. The same year 272,037 tons of igneous rocks were raised, 172,651 tons of limestone, 131,748 tons of clay, and 36,757 tons of sandstone. There is a general decline in the output of the more valuable minerals, but a considerable quantity of pig-iron is produced by the blast furnaces at Ironbridge and Shifnal, the quantity in 1885 amounting to 44,732 tons, in 1890 to 43,084 tons, in 1895 to 49,010 tons, and in 1899 to 40,597 tons. Lead is obtained at Minsterley, and barytes at Minsterley, Pontesbury, Stiperstones, and Chirbury. The following table gives particulars regarding some of the more valuable minerals in 1890 and 1899:—

Year.	Barytes.		Coal.		Iron.		Lead.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.	Tons.	Value.
1890	4838	£6088	766,629	£229,988	44,680	£17,852	1972	£18,927
1899	5080	4567	766,219	287,832	28,571	16,394	1468	14,414

Shusha, a district town of Transcaucasia, Russia, in the government and 87 miles south-south-east of the town of Elizabethpol, situated at an altitude of 1380 feet. Various domestic industries, the chief of which are silk-weaving and the manufacture of leather, are carried on by its inhabitants. In 1897 its population was 25,656.

Shustav. See ARABISTAN.

Shuválof (sometimes written SCHOUVALOFF), **Peter Andreivitch,** COUNT (1827–1889), was born in 1827 of an old Russian family which rose to distinction

and imperial favour about the middle of the 18th century. Several of its members attained high rank in the army and the civil administration, and one of them may be regarded as the founder of the Moscow University and the St Petersburg Academy of the Fine Arts. As a youth Count Peter Andreivitch showed no desire to emulate his distinguished ancestors. He studied just enough to qualify for the army, and for nearly twenty years he led the agreeable, commonplace life of a fashionable officer of the Guards. In 1864 Court influence secured for him the appointment of Governor-General of the Baltic Provinces, and in that position he gave evidence of so much natural ability and tact that in 1866, when the revolutionary fermentation in the younger section of the educated classes made it advisable to place at the head of the political police a man of exceptional intelligence and energy, he was selected by the Emperor for the post. In addition to his regular functions, he was entrusted by his Majesty with much work of a confidential, delicate nature, including a mission to London in 1873. The ostensible object of this mission was to arrange amicably certain diplomatic difficulties created by the advance of Russia in Central Asia, but he was instructed at the same time to prepare the way for the marriage of the Grand Duchess Marie Alexandrovna with the duke of Edinburgh, which took place in January of the following year. At that time the Emperor Alexander II. was anxious to establish cordial relations with Great Britain, and he thought this object might best be attained by appointing as his diplomatic representative at the British Court the man who had conducted successfully the recent matrimonial negotiations. Count Shuválof was accordingly appointed ambassador in London; and he justified his selection by the extraordinary diplomatic ability he displayed during the Russo-Turkish war of 1877–78 and the subsequent negotiations, when the relations between Russia and Great Britain were strained almost to the point of rupture. After the publication of the Treaty of San Stefano, which astonished Europe and seemed to render a conflict inevitable, he concluded with Lord Salisbury a secret convention which enabled the two Powers to meet in congress and find a pacific solution for all the questions at issue. In the deliberations and discussions of the congress he played a leading part, and defended the interests of his country with a dexterity which excited the admiration of his colleagues; but when it became known that the San Stefano arrangements were profoundly modified by the Treaty of Berlin, public opinion in Russia condemned him as too conciliatory, and reproached him with having needlessly given up many of the advantages secured by the war. For a time Alexander II. resisted the popular clamour, but in the autumn of 1879, when Prince Bismarck assumed an attitude of hostility towards Russia, Count Shuválof, who had been long regarded as too amenable to Bismarckian influence, was recalled from his post as ambassador in London; and after living for nearly ten years in retirement, he died at St Petersburg in 1889. (D. M. W.)

Shwebo, a district in the Sagaing division of Upper Burma; area, 8376 square miles; population (1891), 230,779; (1901), 287,049, an increase of 24·4 per cent. It lies between the Katha, Upper and Lower Chindwin, and Mandalay districts. The Irrawaddy forms the dividing line on the east. The physical features of the district vary considerably. The Minwun range runs down the whole eastern side, skirting the Irrawaddy. In the north it is a defined range, but at Sheinmaga, in the south, it sinks to an undulation. West of the Mu river, in the centre of the district, there is a gradual ascent to the hills which divide Sagaing from the Upper Chindwin. Between these ranges and on both sides of the Mu is a plain, unbroken except for some isolated hills in the north and north-east and the low Sadaung-gyi range in the south-east. The greater part of this plain is a rice-growing tract, but on the sloping ground maize, millets, sesamum, cotton, and peas are raised. A good deal of sugar is also produced from groves of the Tari palm. The Mu river is navigable for three months in the year, from June to August, but in the dry weather it can be forded almost anywhere. A good deal of salt is produced in a line which closely follows the railway. Coal is worked at Kabwet.

There are about 1050 square miles of protected forest east of the Mu, and in the Ye-u subdivision, to the west of the river, there are 800 square miles reserved. The Ye-u forests are much more valuable than those to the east on the Minwun and the Mudein. Extensive irrigation works existed in the Shwebo district, but they fell into disrepair in King Thebaw's time. Chief of these was the Mahananda Lake. A scheme to restore the old works has been prepared. The rainfall follows the valleys of the Mu and the Irrawaddy, and leaves the rest of the district comparatively dry. It varies from an average of 31 to 34 inches in Shwebo. The average temperature is 90° in the hot weather, and falls to 60° or 61° in the cold season, the maximum and minimum readings being 104° and 56°. There were in 1898–99, 1200 villages, paying Rs.5,29,292. The amount of cultivated land in the same year was 217,654 acres, and there remained 653,421 acres available.

Sialkot, a town and district of British India, in the Rawalpindi division of the Punjab. The town is 72 miles north-east of Lahore. Population (1881), 45,762; (1891), 65,087; municipal income (1897–98), Rs.1,01,032; death-rate (1897), 33 per thousand. It is a military cantonment. It has manufactures of paper, cotton cloth, and shawl-edging. There are Scottish and American missions and a Scottish mission college, with 14 students in 1896–97, four high schools, a Christian training institute, and 4 secondary schools for girls.

The district of SIALKOT has an area of 1991 square miles; population (1881), 1,012,148; (1891), 1,119,817, showing an increase of 11 per cent.; average density, 562 persons per square mile. In 1901 the population was 1,084,515, showing a decrease of 3 per cent. The land revenue and rates in 1897–98 were Rs.16,91,323, the incidence of assessment being R.1:2:9 per acre; cultivated area, 820,056 acres, of which 504,363 were irrigated, almost all from wells; number of police, 563; number of schools, 411, attended by 13,875 boys, being 14 per cent. of the boys of school-going age; death-rate (1897), 24·9 per thousand. The principal crops are wheat, barley, maize, millet, sugar-cane, and cotton. There are no Government canals. The district is crossed by a branch of the North-Western Railway from Wazirabad to Jamu.

Siam, known to its inhabitants as Muang Tai, the last independent kingdom of Indo-China, consists geographically of two distinct portions. 1. Upper Siam, constituting the heart of the Indo-Chinese peninsula, is bounded, to the east of Chieng Sen (20° 15′ N. and 100° 5′ E.), by the Me Kong or Cambodia river, which, after the Franco-Siamese treaty of 1893, formed the western frontier of the French Indo-Chinese possessions down to 13° 13′ N. By the Franco-Siamese Convention of October 1902, the frontier between Siam and Cambodia starts on the left bank of the Great Lake from the mouth of the Stang Rolnos river, and follows the parallel of latitude eastwards until it meets the Prek Kompong Tiam river. Then, turning northwards, it coincides with the meridian from this point of meeting up to the Pnom Dang Rek mountains. Thence it follows the watershed between the Nam Sen and Me Kong basins on the one hand, and meets the Pnom Padang chain, the summit of which it follows eastwards to the Me Kong, leaving to France the old Cambodian province of Meluprey and the Laos province of Bassac. The northern frontier between Luang Prabang (right bank) and the provinces of Muang Phichaï and Muang Nan was also rectified. Westwards from Chieng Sen and southwards to Kra (10° 30′ N.), the frontier dividing Siam from British Burma is formed by the high forested ranges which make the water-parting between the Bay of

Physical geography.

Bengal and the Gulf of Siam with the exception of an interval between the 15th and 19th parallels, where the Salween and the Taung-yin rivers form a portion of the frontier line. 2. Lower Siam comprises the portion of the Malay Peninsula under Siamese rule, which, from the 10th parallel southwards until Province Wellesley is reached in 5° 33′ N., stretches from sea to sea. It includes the protected Malay states of Keda on the west and of Kelantan and Trengkanu on the east, the frontier between the Siamese possessions and the British protected states of Perak and Pahang running in a general east-south-east direction to the coast in about 4° 20′ N., which is the southernmost point of Siam.

The two important geographical features of Upper Siam are the basin of the Me Nam and the Korat plateau, which lies at a mean elevation of about 600 feet above sea-level and occupies a rectangular area of over 70,000 square miles. It is characterized by tracts of open shadeless jungle, alternating with wide swamps and salt wastes. It is drained by a number of unimportant streams flowing to the Me Kong; the only river of importance is the Nam Mụn, which drains the whole of the southern portion of the plateau. The Lao population is sparsely scattered in small villages, usually along the river banks, there being only four towns of any importance—Korat, Ubon, Bassac, and Nawng Kai. But it is the Me Nam basin which constitutes in more senses than one the heart of Siam. Geographically, the tributaries of the river form trenches cut from north to south through the rough hill country of the Lao states. The successive capitals of the Siamese were planted by the banks of the Me Nam, and the greater part of the population of the country is to this day settled upon it and its many creeks. At the north-east and north-western corners of the gulf the two rivers, the Bang Pa Kong and the Me Kong, flow to the sea, draining—the one the southern slopes of the Dawng Praya Yen and the rich rice districts of Pachim, Nakawn-Nayok, and Petriu; the other, the steep eastern valleys of the Tenasserim frontier range and the garden lands of Kanburi and Ratburi. Both these rivers are connected by an admirable series of navigable canals with the Me Nam and Tachin channels.

The mountain districts encircling the head-waters of the Me Nam, which deflect the Me Kong eastwards along the 20th parallel, do not rise to any considerable height. On the west the watershed between the Salween and the Me Nam is more marked, and develops as it stretches southwards into the well-defined granite wall which, with a slight interruption at Kra, forms the backbone of the Malay Peninsula as far as Junk Ceylon, in 8° N., from which point a fresh range, rising to the eastwards in the province of Nakawn Si Tamarat, takes up its functions.

On the eastern side of the gulf, between the 11th and 13th parallels, the hill system of the Patat range and of Chantabun occurs, cutting off the Cambodian plains from the sea, and itself quite isolated from the hill districts of Indo-China by the plains of the Kabin and Sisopon rivers on the north and east. At the same time the geological conditions may be compared with those of the Me Kong valley of the 20th parallel. The basaltic outcrops, in the neighbourhood of which the gem deposits of both districts occur, although of different ages, are similar in their mode of occurrence; the metamorphic schists of the Me Kong are represented in the Chantabun area by hard quartz grits. The limestones of the Kaw Chang group of islands show much the same symptoms of dislocation as those which form the prominent peaks of the Me Kong region. The general geological structure of both areas, however, in contradistinction to that of the Malay Peninsula, is of a very complicated nature, and needs a more careful and detailed examination than has yet been possible. The limestones referred to are a most striking feature of Indo-China, and appear to be of Carboniferous age. The fragments of this once vast formation are found tilted, contorted, and weathered in inaccessible peaks and precipices from Perak to Tongking, their caves affording protection to many Buddhist shrines and to colonies of nesting swiftlets (chiefly Peate's *Collocalia spodiopygia*), from which Chinese epicures derive their birds'-nest soup. In many parts of Siam, on the other hand, dolomitization has taken place on a large scale.

Climate.

Although enervating, the climate of Siam, as is natural from the position of the country, is not one of extremes. The wet season—May to October—corresponds with the prevalence of the south-west monsoon in the Bay of Bengal. The full force of the monsoon is, however, broken by the western frontier hills; and while the rainfall at Mergui is over 180, and at Moulmein 240 inches, that of Bangkok seldom exceeds 54, and Chiengmai records an average of about 42 inches. Puket and Chantabun, being both on a lee shore, in this season experience rough weather and a heavy rainfall; the latter, being farther from the equator, is the worst off in this respect. At this period the temperature is generally moderate, 65° to 75° F. at night and 75° to 85° by day; but breaks in the rains occur which are hot and steamy. The cool season begins with the commencement of the north-east monsoon in the China Sea in November. While Upper Siam enjoys a dry climate with cool nights (the thermometer at night often falling to 40°–50° F., and seldom being over 90° in the shade by day), the eastern coast of the Malay Peninsula receives the full force of the north-easterly gales from the sea. This lasts into February, when the northerly current begins to lose strength, and the gradual heating of the land produces local sea breezes from the gulf along the coast-line. Inland, the thermometer rises during the day to over 100° F., but the extreme continental heats of India are not known. The comparative humidity of the atmosphere, however, makes the climate a trying one for Europeans.

The rainy season is generally the most unhealthy, various forms of malarial fever, especially violent in the hill districts, being then prevalent. By far the largest percentage of deaths among the people are due to this cause. Dysentery and cholera, which are endemic, are most frequent in the plains at the conclusion of the dry season and during the first rains. Cholera is for the most part confined to the natives, and in Bangkok is principally due to the want of a proper water-supply, the people drinking the water of the river and canals.

Flora.

In its flora and fauna Siam combines the forms of Burma and the Shân States with those of Malaya, farther south, and of Cambodia to the south-east. The teak tree grows all over the hill districts north of latitude 15°, but seems to attain its best development on the west, and on the east does not appear to be found south of 17°. Most of the so-called Burma teak exported from Moulmein is floated down from Siamese territory. Among other valuable forest products are thingan wood (*Hopea adorata*), largely used for boat-building; damar oil, taken throughout Indo-China from the *Dipterocarpus levis*; agilla wood, sapan, rosewood, iron-wood, ebony, rattan, and a number of finely-grained woods, which, with cotton, silk, tobacco, and many spices, will become accessible to the market as communications improve. Among the chief productions of the plains are rice (the staple export of the country); pepper (chiefly from Chantabun); sirih, sago, sugar-cane, cocoa-nut and betel, Palmyra or sugar and attap palms; many forms of banana and other fruit, such as durian, orange-pommelo, guava, bread-fruit, mango, jack fruit, pine-apple, custard-apple, mangosteen. In the hill country of the northern Lao States more temperate forms, such as oak, pine, and chestnut, are found.

Fauna.

Few countries are so well stocked with big game as is Siam. Chief of animals is the elephant, which roams wild in large numbers, and is extensively caught and tamed by the people for transport. The tiger, leopard, fishing-cat, leopard-cat, and other species of wild-cat, as well as the honey-bear, large sloth-bear, and one- and two-horned rhinoceros, occur. Among the great wild cattle are the formidable gaur, or seladang, the banting, and the water-buffalo. The goat antelope is found, and several varieties of deer. Wild pig, several species of rats, and many bats—one of the commonest being the flying-fox, and many species of monkey—especially the gibbon—are also met with. Of snakes, 56 species are known, but only 12 are poisonous, and of these 4 are sea-snakes. The waters of Siam are particularly rich in fish. The crocodile is common in many of the rivers and estuaries of Siam, and there are many lizards—the largest, the water monitor, growing to a length of over 7 feet. The country is rich in birds, a large number of which appear to be common to Burma and Cambodia.

The mineral products of Siam include tin; gold, which is dis-

seminated in small quantities in nearly all the important river deposits; isolated reef workings have not as yet met with very great success; iron (limonite and hematite), which is locally worked; and other ores which, owing to the inaccessibility of the most mineralized zones, cannot in present circumstances pay commercially, and have not as yet been adequately prospected. Salt is also produced in some quantities for local consumption. Sapphires are worked by Shân diggers at Pailin on the eastern slopes of the Patat range, and have been found at Chieng Kawng and elsewhere. The Siam rubies, mostly from Chantabun, are generally inferior in colour to the Burma stones.

Minerals.

The total population is roughly estimated at 9,000,000, of whom a third are Siamese, a quarter Chinese or of Chinese descent, and the remainder mainly Lao, with about 500,000 of Cambodian and the same number of Malay origin. There are about 600 Europeans in Bangkok, of whom a third are British, about a quarter are American, and the rest principally German, Danish, and Belgian. There are over 10,000 British Asiatic subjects registered at the consulate. There are, however, no accurate statistics of the population; owing to the high death-rate, it does not multiply at the rate which might be expected. The Siamese race has intermarried so largely with the Chinese and the surrounding peoples that, except in Rayong and some places on the Malay Peninsula, very few undoubtedly pure-blooded Siamese can now be found. The immigration of the Chinese, which dates from very ancient times, continues uninterruptedly; a regular supply is also kept up to all the mining districts of the Malay Peninsula. As has occurred wherever immigrant Chinese have come into contact with the easy-going natives of the neighbouring tropical countries, the Chinese in Siam have acquired the most important share in the trade and industries of the country. There are practically no Chinese women in the country, but the men freely intermarry with Siamese women, and there is growing up a considerable mixed population, especially in the neighbourhood of the capital, who are called *Lukchins*. The Chinese are not loved by the Siamese, but they are tolerated. In fact, they are indispensable, and every form of work and business would be at a standstill without them.

Population.

Another immigration from the north-east has been constant since 1882: that of the Ka Muk and other hill peoples coming from the highlands of south-western China; but the acquisition by France of Luang Prabang and the neighbourhood of the Nam U valley will have the tendency in all probability of checking this movement. While the plain dwellers of Upper Siam consist mainly of the Tai (Siamese in the south and Lao in the north), the population which has been thrust by the Tai immigration into the hill country presents many different types. The Karens of the western frontier range extend northwards from latitude 13°. In the Lao country the Ka peoples, variously named Lawa, Lamet, Ka Hok, Ka Yuen, and Ka Mu, are met with; and in the Me Kong valley and farther east come the Lu, Yao, Yao Yin, Lanten, Meo, and Musur, all of whom have many distinct Yunanese characteristics, and are fine, hardy mountaineers. Around the forest edges of the Korat plateau are found small numbers of Suey, aboriginal tribes answering to the Chong people of the Chantabun and Battambang Chongs hill districts farther south. In the Malay Peninsula, below the southernmost Karen settlements, Malays begin to be met with near the sea, and inland small roving bands of the Sakei and Samang inhabit the higher ranges.

There are very few towns with a population of over 10,000 inhabitants in Siam, the majority being merely scattered townships or clusters of villages, the *muang*, which gives its name to the province, being often merely a few houses round the governor's residence. The more important towns of the delta include Petriu, Pechim, and Kabin on the Bang Pa Kong; Kanburi, Ratburi, and Petchaburi on the west; Ayuthia, the old capital of Siam, Lophaburi, Angtong, Chainat, and Paknam Po on the Me Nam; Saraburi and Lom Sak on the Nam Sak; Pitsunalok, Pichai, and Utaradit on the upper Me Nam, and Raheng on the western branch; while Korat, Ubon, Bassac, and Nawngkai are the only places of importance on the Korat plateau. In the Malay Peninsula, besides Singora on the east coast and Puket on the west, the important points are Bangtapan, Champawn, Chaiya, Nakawn Si Tamaraj, Tani, Kelantan, and Treng Kanu on the east, and Renawng Takua Pa, Trang, and Keda on the west. The principal towns on the Cambodian side are Chantabun, Battambang, Siemrap, and Sicopon. (For the principal centres of population in the Lao States, see under LAO.) The majority of these places are little more than jungle settlements, forming administrative and commercial centres of merely local importance. The capital, Bangkok, has a population of about half a million, and is the seat of a highly centralized system of government; it also contains the residences of all the chief nobles and officials. The town next to Bangkok in importance is Chiengmai, the so-called capital of the north, with a population of at least over 50,000.

The Government of Siam is an absolute monarchy, and the succession to the throne is now limited to the oldest princes of the blood, who are sons of the king. The old office of second king was abolished on the death of its last occupant. There is a council consisting of nine ministers at the head of the departments of foreign affairs, interior, finance, household, war, justice, local government, public works, and education, together with the chief of the staff and the European general adviser. There is also a legislative council, of which the ministers of state are *ex-officio* members, consisting of about sixty nobles appointed by the king. The council exercises legislative functions, and meets every Tuesday for the transaction of its ordinary business. The king is an autocrat in practice as well as in theory. He has an absolute power of veto, and the initiative of measures rests largely with him, though now, with the increasing complexity of government, he naturally leaves many details of administration to his ministers and council. Most departments have the benefit of European advisers, though but little executive power is entrusted to these officials. The Government offices are conducted more or less on European lines. The Christian Sunday is observed as a holiday, and regular hours are prescribed for attendance. But the numerous palace and other functions form a great call on the ministers' time, and the majority of them continue to be very irregular and unbusinesslike in their methods. The king frequently keeps his courtiers in attendance on him through most of the night, so that early hours are, as a rule, impossible for high officials. There is nothing in the nature of a European civil service, and posts are usually obtained by favouritism; but the certificates of proficiency awarded by the education department are every year acquiring a greater value. The drawing up of the new codes, which are to replace the transitory laws, has been entrusted to committees in which European expert advisers are usually included. Among these measures may be mentioned regulations concerning the law of evidence, criminal and civil procedure, pawnshops, mining, harbour, timber marks, village administration, forests, marriage, and secret societies, which have all been drafted under expert European advice. For administrative purposes the kingdom is divided into *muntons* (or circles), at the head of which chief commissioners are appointed from Bangkok, who reside in the circle and are directly responsible to the central Government. Each munton is subdivided on the basis of the old existing provinces, each of which is under a governor (often hereditary), who is directly responsible to the chief commissioner. By the village regulations brought into force in 1897 every province is further subdivided into districts, each under an *amp'ur*, every district into villages under a *kamnan*, who is elected by the village elders, and each village into groups of from ten to twenty families, at the head of each of which an elder is appointed. With the exception of the metropolitan district of Bangkok, all the muntons are under the department of the interior, which also controls the gendarmerie recently established, with excellent results, for the suppression of dacoity. The police have been completely reorganized under Anglo-Indian officials.

Government.

The Siamese have not yet shaken off the system of personal feudalism, if it may be so called, which has prevailed for many centuries in the country. Every nobleman has a large number of retainers, in addition to debt slaves, and the great mass of the people are glad to rely upon some powerful personage for help and protection, and to give him their services in return. There is, however, no such thing as caste, or even caste feeling, and there is a remarkable absence of exclusiveness for so conservative and despotically governed a country, any man, however humbly born, being suffered to rise to the highest position, if only he have the opportunity. There are no hereditary titles, except in the case of royal princes, those in use being conferred for life, and being attached, in practice generally as well as theory, to some particular office. Thus the same title may be held in succession by the different holders of some post in a Government department, a practice which often leads to some confusion.

Social structure.

The revenue in 1898 was approximately estimated at £2,000,000, made up as follows:—

Duties on liquors and general imports, and rice and other exports	£100,000
Farms and monopolies (opium, spirits, gambling, &c.)	1,000,000
Land tax	200,000
Inland dues, taxes, &c.	700,000
Total	£2,000,000

But by 1901–2 the revenue had increased to £2,088,000, while the expenditure was stated to be £2,239,660. The methods of collection have greatly improved under the administration of European revenue officers, and there is much less corruption than formerly; but little has been done to alter the fundamentals of taxation, and the opium, spirit, and gambling monopolies still provide a large portion of the revenue. In 1898 a large number of transit dues were abolished, thus removing one of the most

Finance.

serious obstacles to commercial development. With the adoption of more business-like methods, no doubt the budget will be regularly published.

Army and navy. The army consists of a small standing force of about 4000 men. The navy comprises several steam gunboats under 600 tons, armed with small quick-firing guns; the king's yacht, a steel twin-screw cruiser of 2500 tons, armed with 6, 4·7, and other smaller quick-firing guns; and a number of small craft for river and coast work, which are manned by several thousand bluejackets and marines, who constitute a very efficient body of men. Most of the soldiers and sailors are descendants of old prisoners of war, and the obligation to this form of service is transmitted from father to son.

Justice. The department of justice has since 1893 been completely re-organized, and the reorganization of the provincial courts has been extended to seven muntons with admirable results. Extra-territorial jurisdiction is secured by treaty for the subjects of all the chief foreign Powers, who can therefore only be sued in their consular courts, while European assessors are employed in cases where foreigners sue Siamese. The prisons have been greatly improved, and a considerable check has been put on thieving in the capital by the passing of the Pawnshops Act in 1901.

Slavery. It may be stated here that the gradual abolition of slavery, which was the first important measure of the King Chulalongkorn's reign, was nearly completed by 1886, although the law is often evaded, as serfdom offers to many a convenient method of paying off debts. The corvée, which is quite distinct from slavery, and is the survival of the old system of personal feudalism which once prevailed in Siam, has been abolished in the outlying provinces, but still lingers in the neighbourhood of the capital. Obligation to personal service is being gradually commuted for money payment.

Religion. While the pure-blooded Malays of the Peninsula are Mahommedans, the Chinese in Siam adhere to the mixture of cowardice and superstition which does duty for a religion in most parts of China. The Siamese and Lao profess a form of Buddhism which is tinged by Cingalese and Burmese influences, and, especially in the more remote country districts, by the spirit-worship which is characteristic of the imaginative and timid Ka and other hill peoples of Indo-China. In the capital a curious admixture of early Brahminical influence is still noticeable, and no act of public importance takes place without the assistance of the divinations of the Brahmin priests. The Siamese, as Southern Buddhists, pride themselves on their orthodoxy; and now that Burma, like Ceylon, has lost its independence, the king regards himself in the light of the sole surviving defender of the faith. There is a close connexion between the laity and priesthood, as the Buddhist rule, which prescribes that every man should enter the priesthood for at least a few months, is almost universally observed, even young princes and noblemen who have been educated in Europe donning the yellow robe on their return to Siam. A certain amount of scepticism prevails among the educated classes, and political motives may contribute to their apparent orthodoxy, but there is no open dissent from Buddhism, and those who discard its dogmas still, as a rule, venerate it as an ethical system. Many of those, it is to be feared, who enter the priesthood for life do so from motives of laziness; and it is to be regretted that so much of the strength of Siamese manhood is thus frittered away, but the accounts given by some writers as to the profligacy and immorality in the monasteries are probably greatly exaggerated. Some of the temples in the capital are under the direct supervision of the king, and in these a stricter rule of life is observed. A few of the priests are learned in the Buddhist scriptures, and most of the Pali scholarship in Siam is to be found in temples, but there is no learning of a secular nature. There is little public worship in the Christian sense of the word. On the Buddhist Wan Phra (or Sunday) the temples are nearly empty, and those who do attend are entirely women. Religious or semi-religious ceremonies, however, play a great part in the life of the Siamese, and few weeks pass without some great function or procession, greatly to the detriment of public business. Among these the cremation ceremonies are especially conspicuous. The more exalted the personage the longer, as a rule, is the body kept before cremation. Thus the late Crown Prince was not cremated until six years after his death. The cremations of great people, which often last several days, are the occasion of public festivities and are celebrated with processions, theatrical shows, illuminations, and fireworks. The missionaries in Siam are entirely French Roman Catholics and American Protestants. They have met with little success among the Siamese, who take their religion as lightly as the rest of life, and discard Christianity as readily as they adopt it. There are, however, a fair number of Chinese converts, especially to Roman Catholicism, and the French cathedral in Bangkok is well attended. The missionaries have nevertheless done much to help on the general work of civilization, and the progress of education has been largely due to their efforts.

Education. As in Burma, the Buddhist monasteries scattered throughout the country carry on the whole of the elementary education of the country. By means of regular Government supervision and control, the monastic schools are to be brought into line with the new Government educational organization. In the metropolitan district of Bangkok there are 290 of these monasteries, containing 8700 monks and novices, of the former of whom more than 400 are teachers. There are 61 Government schools, of which 56 receive grants in aid and 5 are entirely supported by the Government. There are 5 Anglo-vernacular schools for boys and 2 for girls in Bangkok, and there is also a normal college for training teachers for English and Siamese schools. In the interior there are over 4400 monastic schools, with a total of nearly 50,000 inmates of all classes, and 4000 teachers in Siamese and Pali. There are also 70 Roman Catholic missionary schools in the country, with about 4000 pupils, and the Protestant missionaries have eight schools, with about 500 pupils, not including the Chiengmai district.

The education for the most part does not rise above the elementary standard, though the two chief Anglo-vernacular schools are developing into secondary schools. All the work in the upper classes of these schools is in English. French is an optional subject. The schools in the *wats* or temples are being gradually improved. The buildings are being adapted to educational requirements, the priests are provided as far as possible with lay assistants, and a system of inspection is being organized, while the sum spent annually on education was increased nearly fourfold between the years 1899 and 1901. Two scholarships are given every year to boys under nineteen for the purposes of education in Europe, and other students are sent to England and elsewhere at the king's or their parents' expense. The system of teaching boys in the *wats* has caused education to be widely diffused in Siam, and most men can read and write a little. But Siam has no literary or scientific achievements to boast of. The boys, however, are teachable, and up to a certain age distinctly bright and clever.

Communications. All travelling in the delta and far into the interior has been by boat along the rivers, canals, and creeks which intersect the country. Buffaloes and oxen are used for ploughing, and for carting when water transport is not available. In the hill country the elephant, the pack bullock, ponies, the Yunnanese mule, and even men, are used extensively.

Railways. A steam tram, 16 miles in length, from the capital to Paknam at the mouth of the river, opened in 1893, was the pioneer line of the country. That to Korat, 170 miles in length, was completed at the close of 1900, and has already shown an excess of earnings over expenses on sections below the forest belt. An extension northwards to Lophburi (26 miles) on what should be the main line to Chiengmai and the north was opened in January 1901. Another line was begun through the rich country of the delta westward of Bangkok to Ratburi and Petchaburi: it is to be hoped that the short-sighted policy of the Government in allowing the main canals of this easily accessible district to silt up and become useless will not be continued.

Roads. Though there are about 40 miles of good streets in Bangkok and 10 of carriage roads, there has been no road-building or bridging done in the country, with the exception of a few miles near Chiengmai and in various provinces of the Malay Peninsula, the result of abnormal energy and generosity on the part of local governors. Hence all overland travelling involves slow and laborious marching over rough jungle trails.

Posts and telegraphs. A postal service has been extended to all parts of Siam, the country having entered the Postal Union in 1885. The service works as well as can be expected in the present state of communications. Much enterprise has been shown in clearing and laying telegraph lines throughout the country; but few of them work satisfactorily for more than a few months at a time—a fact due as much to ignorance and carelessness on the part of the operators as to the ravages caused by floods and by inquisitive and playful elephants.

Trade. The trade of the port of Bangkok shows a steady increase. But, to estimate the total foreign trade of the country, it is necessary to add to its figure those of other routes. What trade there was across the Me Kong dwindled to vanishing-point after the acquisition of the left bank by France in 1893, though a revival may be hoped for in the future. The trade between French and Siamese Cambodia is also at present insignificant. The total exports for 1901 were £4,292,640, and imports £2,707,370, a total of over seven millions, of which nearly £6,000,000 are by Bangkok and about a million by the east and west coasts of the Malay Peninsula. Of the total, about 80 per cent. represents the value of the direct trade with British possessions, including Hong Kong, Bombay, the Straits, Burma, and the Shân States.

By the convention made between Great Britain and France, and signed at London on 15th January 1896, the Governments of those countries engaged not to advance armed forces into the region which is comprised in the basins of the Petchaburi, Me Kong,

Me Nam, and Bang Pa Kong (Petriu) rivers, and their respective tributaries, together with the extent of coast from Muang Bang Taphan (on the west) to Muang Pase (on the east side of the gulf), the basins of the rivers on which those two places are situated, and the basins of the other rivers the estuaries of which are included in that coast; and including also the territory lying to the north of the basin of the Me Nam, and situated between the Anglo-Siamese frontier, the Me Kong river, and the eastern watershed of the Me Ing. This guarantee affects by far the most populous and flourishing portion of Siam. (H. W. SM.)

HISTORY.

The history of modern Siam may be said to commence with the ratification of the treaty of friendship and commerce concluded with Great Britain in 1855, and negotiated through Sir John Bowring. There had been previous treaties, but this one first put the relations of Siam with Great Britain on their present basis, and it has been followed by treaties on similar lines with France, the United States, Germany, Russia, Japan, and other Powers. The most noteworthy feature of this treaty was the provision of extra-territorial consular jurisdiction, the result of which is that British subjects can only be tried for criminal offences or sued in civil cases in their own consular courts. A large portion of the work of the foreign consuls, especially the British, is consequently judicial, and in 1901 the office of judge was created by the British Government, one of the consuls being appointed to this post. Various commercial regulations were also included in the treaty of 1855, and subsequently trade steadily increased, especially with Great Britain and the British colonies of Hong Kong and Singapore.

The peaceful internal development of Siam seemed also likely to be favoured by the events that were taking place outside her frontiers. For centuries she had been distracted by wars with Cambodians, Peguans, and Burmans, but the incorporation of Lower Cochin China, Annam, and Tongking by the French, and the annexation of Lower and Upper Burma successively by the British, freed her from all further danger on the part of her old rivals. Unfortunately, she was not destined to escape trouble. The frontiers of Siam, both to the east and the west, had always been vague and ill-defined, as was natural in wild and unexplored regions inhabited by more or less barbarous tribes. The frontier between Siam and the new British possessions in Burma was settled amicably and without difficulty, but the boundary question on the east was a much more intricate one and was still outstanding. Disputes with frontier tribes led to complications with France, who asserted that the Siamese were occupying territory that rightfully belonged to Annam, which was now under French protection. France, while assuring the British Government that she laid no claim to the province of Luang Prabang, which was situated on the east or left bank of the upper Me Kong, roughly between the 18th and 20th parallels, claimed that farther south the Me Kong formed the true boundary between Siam and Annam, and insisted on the Siamese evacuating certain posts which they held to the east of the river. The Siamese refused to yield, and early in 1893 encounters took place between them and the French, in which a French officer was captured and French soldiers were killed. The Siamese continued to resist, though the British Government counselled moderation; and the French despatched two gunboats, which forced their way up the Me Nam on 13th July 1893, after a short engagement at the mouth of the river, and anchored at Bangkok, in spite of the protests of the Siamese, who, on their interpretation of clause 15 of the treaty of 1856, asserted that the French were not allowed to send war vessels beyond Paknam without their consent. The French now greatly increased their demands. They insisted on the Siamese giving up all territory to the east of the Me Kong, including the province of Luang Prabang, and also on the neutralization of a zone of 25 kilometres to the west of the Me Kong. After some delay, during which the French blockaded the Me Nam from 25th July to 3rd August for the purpose of enforcing their demands, the Siamese at length gave way, and a treaty was signed with the French on 3rd October 1893. It was agreed that the French should occupy Chantabun until the terms of the treaty were carried out. They remained in possession of it until the conclusion of the further treaty of 1902, which stipulated that it should be evacuated upon the handing over to France of the provinces of Meluprey and Bassac and the ceded territory generally, which extended altogether to 20,000 square kilometres. By this treaty the king of Siam further bound himself to permit ports, canals, and railways in the Siamese portion of the basin of the Me Kong to be constructed by French *personnel* and capital in the event of Siam being unable to accomplish such works unaided.

There remained the question of the frontier between the French and British possessions to the north of Siam. By its conquest of Upper Burma Great Britain had obtained suzerainty over the Burmese Shân States, which stretched across the river Me Kong to the north of Siam, and lay between the 20th and 23rd parallels. It was the intention of the British Government, by ceding the northern portion of these states to China and the southern portion to Siam, to create a buffer state between the French and British possessions, so that they should be nowhere coterminous. Prolonged negotiations took place between the French and British Foreign Offices, but the object of the British was not achieved, and the French were suffered to extend their frontier in this region also as far as the Me Kong. These negotiations, however, though their immediate purpose was not fulfilled, bore important fruit in the Anglo-French convention of 15th January 1896. The chief provision of this convention was the neutralization by Great Britain and France of the central portion of Siam, consisting of the basin of the river Me Nam, with its rich and fertile land, which contains most of the population and the wealth of the country. Neither the eastern provinces bordering on the French possessions nor those of the Malay Peninsula were included in this agreement, but nothing was said to impair or lessen in any way the full sovereign rights of the king of Siam over these territories. Siam thus constitutes a buffer state, with its independence guaranteed by the two European Powers who alone have interests in Indo-China, between Burma on the west and the French possessions on the east, though to the north of Siam the river Me Kong forms, from the point where it leaves China, the only division between the French and British spheres. Siam has therefore a considerable political interest for Europe, not unlike that of Afghanistan, which forms a buffer state between the Russian and British possessions on the north of India. This interest has, however, been for many years enhanced by the fact that Siam, apart from the value of her own trade and her actual and potential wealth, has been regarded in some quarters as affording a possible means of trade access to the provinces of southern China. The French undoubtedly had Chinese trade as their objective when they sent their expedition of exploration, under de Lagrée, up the Me Kong in 1866. This expedition proved a failure, the Me Kong being found to be of little use for purposes of navigation north of the 14th, or at most the 18th, parallel, owing to the prevalence of rapids. But though the French turned their attention subsequently to Tongking and the Red River, the events of 1893 seem to indicate that they still attach some value to the Me Kong as a waterway. The Me Nam is, however, vastly superior to the Me Kong in this respect; and when the Siamese complete the railway which they are building to the north through central Siam, important commercial and political developments may be expected to follow.

The importance of Siam, therefore, in European eyes must consist not only in the fact that it constitutes a buffer state between French and British possessions, but also in the large and increasing stake held by various Western nations in the commerce of the country, and the possibilities it has for the future. Great Britain and British colonies still retain the chief share of the trade, though British shipping in the port of Bangkok has decreased considerably, owing to the transfer of the Singapore and Hong Kong lines of steamships from British to German hands in 1899 and 1900. Other countries too, notably Germany and Denmark, have important trade interests. The independence and prosperity of Siam are therefore matters of no small moment to several European countries. It is impossible, however, to regard the external relations of Siam as not having an intimate connexion with its internal development. Siam is the sole surviving country of tropical Asia that has preserved its independence, and its continued autonomy must depend in great measure on the capacity it shows for self-government. It undoubtedly made great progress in the last quarter of the 19th century. (J. G. D. C.)

Siberia.—A great deal of exploring work has been carried out in recent years in connexion with the Siberian railway, but, valuable though this has been as providing materials for the acquisition of a more detailed knowledge of separate regions, it has not modified our conception of the country generally, as expressed in the article in *Ency. Brit.* vol. xxii. (9th edition) under this head, while the exploration of Manchuria and the Stanovoi range along the coasts of the Sea of Okhotsk has only confirmed the views of the orographical conformation of the country previously set forth. The description of the physical features of Siberia given in the ninth edition still holds good, therefore; and it is sufficient to mention here that the results of recent exploration are especially valuable as regards the ethnology of the inhabitants of Yakutsk, the geography of the Kolyma region in the far north, on the Sea of Okhotsk, the hydrography of the Sea of Okhotsk and the Arctic Ocean, the geography of the Altai, and the economical conditions of the inhabitants of South Siberia.

Physical features.

Population.

At the general census taken in February 1897 the domiciled population was found to be 5,698,924. The natural increase (80,100 per annum) and the registered immigration (by land, 69,149 in 1897, 148,965 in 1898, and 181,895 in 1899; by sea, 2400, 4055, and 8300 respectively) have since added about 800,000, so that on 1st January 1901 the total population must have been about 6,500,000. In 1897 Russians numbered about 4,950,000 (87 per cent.) and the indigenous population about 750,000 (13 per cent.). The distribution of the population according to provinces, with the area of the same, was as follows :—

Province.	Area. Square Miles.	Russians (000 omitted).	Indigenous Population (000 omitted).	Total Population.	Density per Square Mile.
Tobolsk	539,659	1373	65	1,438,484	3
Tomsk	331,159	1865	64	1,929,092	6
Western Siberia	870,818	3238	129	3,367,576	4
Yeniseisk	987,186	517	42	559,902	1
Irkutsk	287,061	402	.105	506,517	2
Yakutsk	1,533,397	40	222	261,731	·2
Transbaikalia	236,868	467	197	664,071	3
Eastern Siberia	3,044,512	1426	566	1,992,221	·7
Amur	172,848	99	19	118,570	·9
Maritime	715,982	185	35	220,557	·3
Amur Region	888,830	284	54	339,127	·3
Sakhalin	29,336	...	...	28,166	1
Total	4,833,496	4948	749	5,727,090	1

The ethnographical composition of the population is given in the ninth edition. It may be added here that though at present forming only a small element in the population, the rapid increase of the Koreans and Chinese in certain districts is of importance. In the Maritime Province, before the Boxer uprising in 1900, 26 per cent. of the population of the North Usuri district and 36 per cent. of the population of the South Usuri district were Koreans and Chinese, and in the Amur province there were nearly 15,000 Manchus and Koreans.

As to Russian immigration to Siberia, it has been organized on new principles, the immigrants being now directed into the regions where there is free land available for them, so that they may avoid the great hardships which they used formerly to undergo. In the eighteen years 1882–99, 1,367,391 came into the country to settle by land, and 41,280 by sea. The former settled mostly in West Siberia (chiefly in the Altai region), while the latter went mainly to the South Usuri district. It is worthy of note that the main flow of immigration was from the fertile northern belt of the black-earth provinces of European Russia, and to a smaller degree from the Lithuanian provinces and the Ural provinces of Perm and Vyatka.[1]

Cities.—Only 8·1 per cent. of the population live in towns (6·4 per cent. only in the governments of Tobolsk and Tomsk). There are fifteen towns with a population of 10,000 or more, namely, Tomsk (52,000) and Irkutsk (51,000)—the capitals of Western and Eastern Siberia respectively; Blagoveschensk (32,000), Vladivostok (29,000), Tyumeñ (29,000) in West Siberia, head of Siberian navigation; Barnaul (29,000), capital of the Altai region; Krasnoyarsk (26,000) and Tobolsk (20,000), both mere administrative centres; Biysk (17,000), centre of Altai trade; Khabarovsk (15,000), administrative centre of the Amur region; and—all with from 10,000 to 11,000 inhabitants—Tchita, the capital of Transbaikalia; Kolyvañ, the centre of the trade of southern Tomsk; Yeniseisk, the centre of the gold-mining region of the same name; Kurgan, a growing town in Tobolsk; and Minusinsk, in the southern part of the Yeniseisk province, trading with north-west Mongolia. Several villages have sprung up very rapidly along the railway line.

Education.

Little has been done towards satisfying, or even giving free scope to, the growing demand for education in Siberia. The petitions for a university at Irkutsk, the money required for which has been freely offered to the Government, have been refused, and the imperative demands of the local tradesmen for technical instruction have likewise met with but little response. The Tomsk University remains incomplete, and has only 500 students. In 1901 the provision for education could be approximately tabulated as follows :—

Province.	Total Number of Schools.	Number in Towns.	Middle Schools.	Special Schools.	Total Number of Scholars.
Tobolsk	588	69[2]	9	5	21,000
Tomsk	2015	70	9	5	48,125
Yeniseisk	235	35	7	2	9,320
Irkutsk	412	70	7	6	13,755
Yakutsk	77	12[3]	...	...	1,507
Transbaikalia	375	45	4	6	12,760
Amur	73	...	..	...	4,600
Maritime Prov.	106	...	...	...	3,470
Sakhalin	28	...	...	...	870
Total	3909	...	...	...	115,407

If the figures in the above table are compared with the total populations of the several provinces, it will be seen at once how inadequate is the provision for education in Siberia. As a rule, the girls form from a quarter to a third of the total number of pupils.

[1] See *Siberia* (in Russian), a manual for immigration published by the Ministry of Agriculture in 1900, with maps of available lands, &c.

[2] 5650 pupils. [3] Also four at the gold mines.

There are 18 scientific societies in Siberia, which issue publications of great value. Twelve natural history and ethnological museums have been established by the exiles—the Minusinsk museum being the best. There are also 20 public libraries, and 11 papers are published in addition to the eparchial *Vyedomosti* published in each bishopric.

Exiles.—Up to 1901 nearly 20,000 exiles continued to be transported every year to Siberia, half of whom were exiled by mere orders of the local and central administration. It was, however, announced officially in 1901 that the system was to be discontinued, and the measures to be taken for this purpose again came under discussion by the St Petersburg committees.

Land Tenure.—Out of the nearly 3,240,000,000 acres of land in Siberia, 3,104,000,000 acres belong to the State, while the cabinet of his Majesty (the emperor reigning at the time being) owns 114,700,000 acres (112,300,000 in the Altai and 2,400,000 in Nerchinsk). Private property is insignificant in extent — purchase of land being only permitted in the Amur region. (In western Siberia it was only temporarily permitted in 1860–68.) In all there are only 1214 private estates, covering an aggregate area of 1,415,845 acres (256,046 acres in the Amur region). Siberia thus offers an example of the nationalization of land unparalleled throughout the world. Any purchase of land within a zone 67 miles wide on each side of the trans-Siberian railway was absolutely prohibited in 1895, and the extent of Crown lands sold to a single person or group of persons never exceeds 1080 acres unless an especially useful industrial enterprise is projected, when the maximum is fixed at 2700 acres. The land is now held by the Russian village communities in virtue of the right of occupation. Industrial surveys, having for their object the granting of land to the peasants to the extent of 40 acres per each male head, with 8 additional acres of wood and 8 acres as a reserve fund, were started many years ago, and after being stopped in 1887 were commenced again in 1898. At the present time the land allotments per male head vary greatly, even in the populated region of southern Siberia. In the case of the peasants the allotments vary on an average from 32 acres to 102 acres (in some cases from 21·6 acres to 240 acres); the Transbaikalian Cossacks have about 111 acres per male head, and the indigenous population from 108 acres to 154 acres.

Agriculture. The total cultivated area and the total area under crops every year have been estimated by A. Kaufmann as follows[1]:—

Province.	Area cultivated, Acres.	Under Crops (Acres). Total.	Average per Household.	Average per 100 Inhabitants.
Tobolsk	5,670,000	3,270,000	13·2	243
Tomsk	8,647,000	5,259,000	15·7	310
Yeniseisk	1,830,000	977,000	13·0	267
Irkutsk	1,800,000	910,000	13·2	265
Transbaikalia	1,415,000	872,000	9·4	159
Yakutsk	81,000	43,000	0·8	16
Amur (Russians)	143,000	143,000	19·4	275
South Usuri (peasants only)	151,000	151,000	24·0	375
	19,737,000	11,625,000	...	...

These figures are somewhat under-estimated, but the official figures for 1900, published by the Statistical Committee, are still lower, especially for Tomsk. The crops yielded in 1900 are officially given, for four governments only, as follows:—

1900.	Rye.	Wheat.	Barley.	Oats.
	Thousands of cwt.			
Tobolsk	1753	3888	467	3610
Tomsk	2338	5413	436	4351
Yeniseisk	1770	989	105	1154
Irkutsk	2065	517	265	863
Total	7926	10,807	1273	9978
Percentage of the average crops of 1895–99	62	53	52	59

These crops, as is seen from the last row of figures, were only between a half and two-thirds of the average crops for the five preceding years. The comparison with the crop of 1899 is still more unfavourable, the net produce of cereals available for the population being only 4·2 cwt. per inhabitant in 1900, as against 11·9 cwt. in 1899. This gives an illustration of the way in which the crops fluctuate in Siberia, and indeed the yield in a very good year will be almost three times that in a very bad one. The prices vary still more, the maximum being from 12 to 20 times (in 1892) higher than the minimum. Altogether it may be said that the southern parts of Tobolsk, nearly all the province of Tomsk (exclusive of the Narym region), southern Yeniseisk, and southern Irkutsk have in an average year a surplus of grain which may represent from 35 to 40 per cent. of the total crop, but that in bad years the crop falls short of the actual needs of the population. There is considerable movement of grain in Siberia itself, the populations of vast portions of the territory, especially of the mining regions, having to rely upon imported corn. Consequently at the present time Siberia is not a grain-exporting country of any importance, although it may become so, especially when the Altai region is more populated than it is now. (See ALTAI.) The forest area under supervision is about 30,000,000 acres (in Tobolsk, Tomsk, Yeniseisk, and Irkutsk), out of a total area of forest land of 63,000,000 acres.

Live Stock.—As an independent pursuit, cattle-breeding is carried on by the Russians in eastern Transbaikalia, by the Yakuts in the province of Yakutsk, and by the Buriats in Irkutsk and Transbaikalia, but elsewhere it is secondary to agriculture. The numbers of the live stock have been estimated by A. Kaufmann as follows (small cattle not being separated from the full-grown):—

Province.	Horses.	Horned Cattle.	Sheep and Goats.	Pigs.	Reindeer.
Tobolsk	736,230	985,520	1,097,810	226,520	186,460
Tomsk	2,307,740	1,919,890	3,694,090	535,330	...
Yeniseisk	470,750	297,740	590,000	52,000	...
Irkutsk[2]	234,490	314,610	322,170	62,630	...
Transbaikalia	628,290	1,405,110	1,379,430	138,760	...
Yakutsk	117,230	213,400	360	...	19,960
Amur[3]	22,190	25,520	3,680	...	...
Usuri[4]	10,080	32,610	13,790[5]	...	...
Total	4,527,600	5,194,400	7,101,930	1,015,240	206,420

Till lately, hides, tallow, and meat for the mining centres were the main exports of Siberia; butter was also exported, but of low quality. At the present time the making of butter in co-operative creameries, introduced by the Danish co-operators, has rapidly developed in West Siberia; improved machinery is being manufactured and used in the villages, and butter is already a substantial item in the goods traffic on the Siberian railway.

It is estimated that about one-half of the Russian agricultural population supplement their income by engaging in non-agricultural pursuits, but not more than from 18 to 22 per cent. carry on domestic trades, the others finding occupation in the carrying trade—which remains important, even after the construction of the railway—in hunting (chiefly squirrel-hunting), and in work in the mines. **Manufactures.** Domestic and petty trades are therefore developed only round Tyumeñ, Tomsk, and Irkutsk. The principal of these trades are the weaving of carpets —about Tyumeñ—which seem to find a sale even in London under various Eastern names; the making of wire sieves; the painting of ikons; the making of wooden vessels and of the necessaries for the carrying trade about Tomsk (sledges, wheels, &c.); the manufacture of felt boots and sheepskins; and, of recent introduction, the manufacture of dairy utensils and machinery. Weaving is also engaged in for domestic purposes. But all these trades are sporadic,

[1] *Russian Encyclopædic Dictionary*, vol. lix., 1900.

[2] District of Kirensk missing.
[3] Owned by Russian population only.
[4] Owned by the peasants only.
[5] All small cattle included.

belonging to limited areas, and often only to a few separate villages. In 1897 all the factories of Siberia numbered only 4651, and employed only 25,200 workers, their yearly returns hardly exceeding 20,000,000 roubles. In short, the want of communications, of technical education, and of skilled workers, coupled with the prospect of rapid enrichment by gold-mining, has hindered all manufacturing industries, though in respect of most fields of industry, the richness of much of the country and the abundant supply of raw materials afford every opportunity for a notable development.

This remark is especially true of mining, which is the main pursuit of the people, after agriculture. The chief centres for gold-mining are the Altai, the Mariinsk district of Tomsk, the southern parts of the province of Yeniseisk, the Yeniseisk district in the north of the same province, the Nerchinsk and the Vitim districts of Transbaikalia, the Olekma and Vitim district of Yakutsk, and the Bureya and Zeya districts of the Amur province; some gold is also extracted by the Chinese in the South Usuri region. All these gold-washings, which were especially flourishing in the 'eighties, employed in 1897, 41,235 workers, and produced 55,147 lb avoir. of gold dust ($\frac{9}{10}$ gold), valued at 24,555,000 roubles after all taxes had been paid. It is supposed that from 1800 to 3600 lb more were obtained fraudulently. Coal-mining is in its infancy, less than 50,000 tons of coal being extracted annually, including that obtained from Sakhalin. Great hopes are entertained, however, for the future of this industry, especially after the Eki-baz-tus mines of Akmolinsk have been connected by rail with the Setysh. Salt is obtained in antiquated works only to the amount of 1,000,000 cwt. per annum, and has to be imported. Its price stands very high in the villages of the interior, and the inhabitants feel the want of it greatly.

Mining.

Fishing is an important source of revenue, especially on the lower parts of the great Siberian rivers and on Lake Baikal; the Amur is as rich in salmon as the rivers of the Pacific slope in America. But the fisheries are still at a primitive stage of their existence, and are hampered by the high price of salt, tinplate materials, &c., and by the lack of skilled knowledge.

Commerce.—There are no figures from which even an approximate idea can be gained of the value of the internal trade of Siberia, but it is certainly considerable. The great fair at Irbit retains its importance, and there are, besides, 507 fairs in Tobolsk, 68 in Tomsk, 13 small ones in Yeniseisk, and from 3 to 12 in Transbaikalia, Irkutsk, and Yakutsk. The aggregate returns of all these is estimated at 25,000,000 roubles. There are also 71 fairs in Akmolinsk and Semipalatinsk, the returns for which are estimated at 13,500,000 roubles. The trade with the natives, which is a source of considerable income to the local merchants, continues to be mainly dependent on the sale of spirits, and to afford endless instances of abuse.

In the external trade the exports to Russia consist chiefly of grain, cattle, sheep, animal products, furs, game, feathers, and down. Trade with China is mainly in tea, which is imported. The total value of the imports from China is on an average about 20,000,000 roubles per annum, but the exports of Russian goods to China hardly attain 1,500,000 roubles per annum. This is because textiles and manufactured goods generally are imported much more advantageously by sea than by the long overland route, and it remains doubtful whether the completion of the trans-Siberian line will alter these conditions. The trade with China *viâ* the provinces of Akmolinsk and Semipalatinsk remains insignificant (total annual returns, about 1,150,000 roubles), as does the trade of Tomsk *viâ* Kom-agach, while the imports and exports from and to Mongolia, *viâ* Ulyasutai, total less than 1,000,000 roubles, and the trade along the Transbaikalian frontier (exclusive of Kyakhta) hardly exceeds 250,000 roubles. Cattle, however, are beginning to be imported in larger quantities from Mongolia. The trade with Manchuria, where large quantities of grain are bought, totals about 985,000 roubles for imports and about 1,100,000 roubles for exports. In 1896 Vladivostok was visited by 78 Russian and 189 foreign ships, the imports being 262,000 tons (60,000 tons for the State) and the exports 50,000 tons, to which the export of nearly 2000 tons by 800 small Chinese and Korean vessels must be added. The chief article of export was edible seaweed, of which about 13,700 tons was shipped to China. It is also estimated that nearly £260,000 worth of imported goods reach Blagoveschensk. The Amur region is no doubt a growing region, which requires various goods for its agricultural and mining population, but the disproportionately large excess of imports over exports clearly indicates that the high customs duties levied, and the difficulties of transport along the Usuri railway and farther up the Amur, prevent the development of the natural resources of the country. As to the northern maritime trade *viâ* the mouths of the Siberian rivers, its results were very satisfactory during the years 1896–98, especially as regards the import of machinery for the northern gold mines, and of brick tea, the sea route proving much more economical than the overland. But in 1899 none of the steamers which started for the Siberian rivers reached them, owing to the ice in the Kara Sea.

Inland Navigation.—Navigation on Siberian rivers has developed both as regards the number of steamers plying and the number of branch rivers traversed. In 1900, 130 private and several Crown steamers plied on the Ob–Irtysh river system as far as Semipalatinsk on the Irtysh, Biysk on the Ob, and Achinsk on the Chulym. Cartographical work of importance has been carried out in the estuaries of the Ob and Yenisei. The Ob–Yenisei canal is ready, but offers difficulties on account of the scarcity of water in the smaller streams forming part of that system, a difficulty which will probably be remedied by the formation of reservoirs. On the Yenisei 18 steamers ply from Minusinsk to Yeniseisk, and to Ghilghiha at its mouth; 10 steamers ply on its great tributary, the Angara, of which some rapids have been cleared, though the Padun rapids have still to be rounded by land; and 10 on the Selenga. On the Lena and the Vitim there are 20 steamers, and a small railway connects the Bodoibo river port with the Olekma gold-washings. On the Amur system, of which the Zeya, the Bureya, and the Amguñ are already navigated, there were 105 steamers in 1900.

Railways.—The first railway to reach Siberia was built in 1878, when a line was constructed between Perm, at which point travellers for Siberia used to strike off from the Kama eastwards, and Ekaterinburg, on the eastern slope of the Urals. In 1884 this line was continued farther into Siberia, so as to reach Tyumeñ, the head of navigation on the Siberian rivers, it being supposed at that time that this line would form part of the projected trans-Siberian railway. But farther south the Russian railway system had already reached as far east as Orenburg, and the Volga had been bridged at Syzrañ in 1880; accordingly, it was finally decided, in 1885, to give a more southerly direction to the great trans-Siberian railway, and to continue the Moscow–Samara line to Ufa, Zlatoust, in the Urals, and Chelyabinsk, in the West Siberian prairies, at the head-waters of one of the tributaries of the Ob. Once this point was reached—and the construction of the railway so far was soon accomplished, without any serious engineering difficulties being encountered—the line had evidently to be continued across the prairies to Kurgan and Omsk, and thence along the great Siberian highway to Krasnoyarsk and Irkutsk. As to its farther direction, it was decided that it would be best to follow, broadly speaking, the great highway round Lake Baikal to Tchita and Sryetensk on the Shilka; then to push down the Amur to Khabarovsk; and finally to proceed up the Usuri to Vladivostok. This general scheme was fixed upon in its broad outlines in 1891, and definitely accepted, after the necessary reconnoitring explorations, in 1892. The building of the railway was begun at several points at once; it had, indeed, been started before this time, the first stone of the line from Vladivostok to Grafskaya, on the Usuri, having been laid on 31st May 1891.

The several sections of the line as now built or planned, are as follows; it will be seen—under (6)—that in its last portions the route had to be somewhat modified: (1) Chelyabinsk to the Ob (Krivoschokovo village), 881 miles. On this stretch the line crosses a fertile prairie very similar to the Winnipeg prairies in Canada, and well populated; it crosses the Tobol, the Ishim, and the Irtysh. (2) From the Ob to Irkutsk, 1137 miles. This part of the line crosses first a slightly higher "rolling prairie" (similar to the Calgary rolling prairie of Canada), and at Achinsk enters the still higher plains of eastern Siberia, crossing the low spurs of the mountain region of South Yeniseisk. Excavations and high embankments had to be made on this last stretch, and several large rivers—Tom, Yaya, Kiya, Oka, Tchulym, all very rapid and liable suddenly to

inundate the surrounding country—had to be crossed, as well as the Yenisei, near Krasnoyarsk. (3) From Irkutsk to Listvenichnaya, on Lake Baikal (41 miles), along the rocky valley of the Angara. (4) Round the southern extremity of Lake Baikal. This section was not yet built in 1902, nor could it be built for some time, on account of the great difficulties offered by the high and craggy mountains (Khamar-daban), sloping precipitously towards the lake, and pouring into it hundreds of streams, each of which is a wild torrent at certain times of the year. Meanwhile two powerful ice-breakers carry the trains over the lake to the Mysovaya station in Transbaikalia. (5) From Mysovaya to Tchita and Sryetensk, on the Shilka, 687 miles. This line gradually ascends by way of the valleys of the Selenga and the Uda to the level of the plateau, and crossing the south-eastern border ridge of this—Yablonovoi Khrebet—at an altitude of 3412 feet, reaches the Tchita river near its junction with the Ingoda. This last river is followed to its junction with the Shilka, and the Shilka down to Sryetensk. (6) For reasons indicated elsewhere (see RUSSIA, *Railways*), it was found inadvisable to continue the railroad along the Shilka and the Amur to Khabarovsk, and negotiations with the Chinese Government for a trans-Manchurian railway were successfully carried out. This line connects Kaidalovo, 20 miles below Tchita, with Vladivostok, with a branch from Harbin, on the Sungari, to Dalny and Port Arthur. Those parts of it which run through Russian territory (in Transbaikalia, from Kaidalovo to Nagadan—216 miles; in the neighbourhood of Vladivostok, from Nikolsk to the Manchurian frontier—72 miles) were in 1902 in working order, and the trans-Manchurian line (1607 miles) was already opened for some traffic. However, parts of it were only in a preliminary state; the crossing of the Great Khingan would be gradually rendered less steep, and the bridge over the Sungari had still to be completed. (7) A line was constructed from Vladivostok to the Amur before it became known that the idea of following the latter part of the route originally laid down would have to be abandoned. This line, which has been in working order since 1898, is 477 miles long, and proceeds first to Grafskaya, across the fertile and populous South Usuri region, then down the right bank of the Usuri to Khabarovsk, across marshy and woody tracts, almost useless for purposes of cultivation.

Returning westwards, it may be noticed that Chelyabinsk has been connected with Ekaterinburg (150 miles); and that a branch line has been built to Tomsk (60 miles). Altogether the trans-Siberian line has been built very rapidly. In 1893, 256 miles of rail were laid down; in 1894, 552 miles; in 1895, 832 miles; in 1896, 454 miles; in 1897, 438 miles; in 1898, 478 miles; in 1899, 490 miles; and in 1900, 288 miles, making a total for the eight years of 3788 miles. The total cost of the 3721 miles already opened for traffic in the first months of 1901 was 327,794,685 roubles, to which the estimated cost of the 193 miles round Lake Baikal, that is, 37,618,900 roubles, has to be added. Various works have also been carried out along the Siberian rivers and at the port of Vladivostok in order to improve navigation, the total cost of which is estimated at 466,110,019 roubles. If the Perm–Kotlas railway and the feeding lines are taken into account, the whole enterprise had cost up to 1902 over 529,000,000 roubles.

AUTHORITIES.—The best recent sources of information about the economical conditions in Siberia are: *Materials for the Study of the Economic Conditions of West Siberia*, 22 vols., St Petersburg, 1889–98; these have been condensed in a book, *Peasant Land-Tenure and Husbandry in Tobolsk and Tomsk*, St Petersburg, 1894. Similar *Materials* for the Altai region, published at St Petersburg by the Cabinet of the Emperor, and for Irkutsk and Yeniseisk, 12 fasc., Irkutsk, 1889–93; *Materials* of States Secretary Kulomzin's Commission for Transbaikalia, 16 vols., St Petersburg, 1898: these have been summed up in a book, *Transbaikalia*, by N. RAZUMOFF, St Petersburg, 1899. Other works deserving special mention are: SYEROSHEVSKIY. *The Yakuts*. St Petersburg, 1896.—BUSSE and RITTICK. *Usuri Region*.—YADRINTSEFF. *Siberia as a Colony*. New edition. 1892.—ERMOLOFF. *Siberia as a Colony*. 3rd edition, 1894.—JARILOW. *Ein Beitrag zur Landwirthschaft in Siberen*. Leipzig, 1896.—SEMEVSKIY. *Gold-Mines Workers*. 1899.—KAUFMANN. *Sketch of Peasant Husbandry in Siberia*. Tomsk, 1894; reprinted in *Siberia and the Great Trans-Siberia Railway*, and in the *Guide* to the Siberian Railway published by the Ministry of Ways and Communications. The article "Siberia," by several contributors, in the *Russian Encyclopædic Dictionary*, vol. XXIXA. 1900. A considerable number of monographs and general works relative to the history of Siberia (all in Russian) have also been published. A full bibliography, up to date, will be found in the above-mentioned article in the *Russian Encyclopædic Dictionary*, as also in MEZHOV, *Siberian Bibliography*, 3 vols., St Petersburg, 1891–92, and in the great work of A. PYPIN, *History of Russian Ethnography*, vol. iv. (P. A. K.)

Sibonga, a town on the east coast of the island of Cebú, Philippine Islands, in 10° 00′ 06″ N. Agriculture is the principal occupation of its inhabitants, rice and copra being the most important products. It has a healthful, though hot, climate. The language is Cebú-Visayan. Population, 23,000.

Sibpur, a town of British India, in the Hooghly district of Bengal, situated in 22° 34′ N. and 88° 16′ E., on the right bank of the river Hooghly, opposite Fort William. It is a suburb of Howrah, with which town its statistics are included. It contains jute-mills, flour-mill, rope-works, brick-works, and other industrial establishments; the Government botanical garden (the Kew of India); and the engineering college, which has been reorganized, with electrical and mining departments and a boarding-house. In 1896–97 there were in all 310 students; and the total cost was Rs.1,09,226, of which Rs.96,481 was paid by Government.

Sibsagar, a town and district of British India, in the Brahmaputra Valley division of Assam. The town is situated on the Dikhu river, about 9 miles from the left bank of the Brahmaputra. Population (1881), 5868; (1891), 5249; municipal income (1897–98), Rs.11,463; death-rate (1897), 42·1 per thousand. The Government high school had 175 pupils in 1896–97, of whom 4 passed the Calcutta matriculation.

The district of SIBSAGAR has an area of 2855 square miles. Population (1881), 370,274; (1891), 457,274, showing an increase of 23 per cent., mainly due to the importation of tea coolies; average density, 160 persons per square mile. Classified according to religion in 1891, Hindus numbered 418,863; Mahommedans, 19,805; Christians, 1365, including 274 Europeans; hill tribes, 16,243; "others," 998. In 1901 the population was 598,642, showing an increase of 31 per cent. The land revenue is Rs.13,26,839, the incidence of assessment being Rs.2:10:11 per acre; number of police, 277; number of boys at school (1896–97), 11,222, being 31·04 per cent. of the male population of school-going age, the highest proportion in the province; death-rate (1897), 42·6 per thousand. Sibsagar is the chief centre of tea cultivation in the Brahmaputra valley, which was introduced by the Assam Company in 1852. In 1897 there were 171 gardens, with 70,644 acres under tea, employing 139,755 persons, of whom 44,193 had been imported under contract, and yielding 24,000,000 ℔, or 391 ℔ per acre. There are 3 timber mills, employing 200 hands, and producing 125,000 tea-chests, of the value of Rs.1,00,000. A small State railway of 2 feet gauge runs from Jorhat to the Brahmaputra, 27 miles long; but the district will shortly be traversed throughout by the Assam-Bengal railway, now under construction.

Sicily.—Sicily is an island separated from the Italian mainland by a strait which in its narrowest part (Strait of Messina) is hardly two miles wide. The area and population of the several provinces are shown in the subjoined table:—

Province.	Area in Square Miles.	Population, 1881.	Population, 1901.	Density per Square Mile, 1901.
Caltanissetta .	1263	266,379	330,972	262
Catania . .	1917	563,457	711,923	371
Girgenti . .	1172	312,487	371,471	317
Messina . .	1246	460,924	548,898	440
Palermo . .	1948	699,151	785,016	403
Syracuse . .	1442	341,526	427,429	296
Trapani . .	948	283,977	353,557	373
Total . .	9936	2,927,901	3,529,266	355

Thus between 1881 and 1901 the population increased at the rate of 20·5 per cent. The average density is extremely high for a country which lives almost exclusively from agriculture, and is much higher than the average for Italy in general, 293 per square mile.

Agriculture and agricultural products.

Sicily, formerly called the granary of Italy, exported grain until the end of the 18th century. Now, although the island still produces every year some 15 million bushels, the supply barely suffices for the consumption of a population of which bread is almost the exclusive diet. The falling-off in the exportation of cereals is not a consequence of any decadence in Sicilian agriculture, but rather of the increase of population, which nearly doubled within the 19th century. Two types of agriculture prevail in Sicily—the extensive and the intensive. The former covers mainly the interior of the island and half the southern coast, while the latter is generally adopted on the eastern and northern coasts. Large holdings of at least 500 hectares (a hectare equals about 2½ acres) are indispensable to the profitable pursuit of extensive agriculture. These holdings are usually called *feudi* or *latifondi*. Their proprietors alternate the cultivation of wheat with that of barley and beans. During the years in which the soil is allowed to lie fallow, the grass and weeds which spring up serve as pasture for cattle, but the poverty of the pasture is such that at least two hectares are required for the maintenance of every animal. This poverty is due to the lack of rain, which, though attaining an annual average of 74 centimetres (29 inches) at Palermo, reaches only 53 centimetres (21 inches) at Syracuse on the east coast, and 49 centimetres (about 19½ inches) at Caltanissetta, on the central high plateau. The system of extensive cultivation proper to the *latifondi* gives an annual average gross return of about 200 lire per hectare (£3, 4s. 5d. per acre).

Intensive agriculture in Sicily is limited to fruit trees and fruit-bearing plants, and is not combined with the culture of cereals and vegetables, as in central and parts of northern Italy. Originally the Sicilian system was perhaps due to climatic difficulties, but now it is recognized in most cases to be more rational than combined culture. Large extents of land along the coasts are therefore exclusively cultivated as vineyards, or as olive, orange, and lemon groves. Vineyards give an annual gross return of between £11 and £13 per acre, and orange and lemon groves between £32 and £48 per acre. Vegetables are grown chiefly in the neighbourhood of large cities. Almonds are freely cultivated, and they seem to be the only trees susceptible also of cultivation upon the *latifondi* together with grain. A large export trade in almonds is carried on with north and central Europe. Hazel nuts are grown in woods at a level of more than 1200 feet above the sea. These also are largely exported to central Europe for use in the manufacture of chocolate. The locust bean (used for forage), figs, and peaches are widely grown, while in certain special zones the pistachio and the manna-ash yield rich returns. On the more barren soil the sumach shrub, the leaves of which are used for tanning, and the prickly pear grow freely. The latter fruit constitutes, with bread, the staple food of the poorest part of the rural population for several months in the year. The cultivation of cotton, which spread during the American War of Secession, is now rare, since it has not been able to withstand the competition of more favoured countries. All these branches of intensive cultivation yield a higher gross return than that of the extensive system. Along the coast landed property is as a rule broken up into small holdings, usually cultivated by their owners.

Climatic conditions prevent cattle-raising in Sicily from being as prosperous an undertaking as in central Italy. The total number of bullocks in the island is calculated to be less than 200,000; and although the ratio of consumption of meat is low in proportion to the population, some of the cattle for slaughter have to be imported. Sheep and goats, which subsist more easily on scanty pasturage, are relatively more numerous, the total number being calculated at 700,000. Yet the wool harvest is scarce, and the production of butter a negligible quantity, though there is abundance of the principal product of Sicilian pasture lands, cheese of various kinds, for which there is a lively local demand. The Sicilian race of horses would be good, but that it is not prolific, and has degenerated in consequence of insufficient nourishment and overwork. A better breed of horses is being obtained by more careful selection, and by crossing with Arab and English stallions imported by the Government. Donkeys and mules of various breeds are good, and would be better were they not so often weakened by heavy work before attaining full maturity.

Forests.

The absence of forests, which cover hardly 3 per cent. of the total area of the island, constitutes a serious obstacle to the prosperity of Sicilian pastoral and agrarian undertakings. The few remaining forests are almost all grouped around Etna and upon the high zone of the Madonian Mountains, a range which rises 40 miles west of Palermo, running parallel to the northern coast almost as far as Messina, and of which many peaks reach nearly 6000 feet above the sea.

In that part of the island which is cultivated intensively some four and a half million hectolitres of wine are annually produced. Had not the phylloxera devastated the vineyards during the last decade of the 19th century, the production would be considerably higher. Three hundred and fifty thousand hectolitres of olive oil and 2500 million oranges and lemons are also produced, besides the other minor products above referred to. The zone of the *latifondi*, or extensive culture, yields, besides wheat, nearly 3,000,000 hectolitres of barley and beans every year.

Mining.

The most important Sicilian mineral is undoubtedly sulphur, which is mined principally in the provinces of Caltanissetta and Girgenti, and in minor quantities in those of Palermo and Catania. Up to 1896 the sulphur industry was in a state of crisis due to the competition of pyrites, to the subdivision of the mines, to antiquated methods, and to a series of other causes which occasioned violent oscillations in and a continual reduction of prices. The formation of the Anglo-Italian sulphur syndicate arrested the downward tendency of prices and increased the output of sulphur, so that the amount exported in 1899 was 4,240,183 quintals, worth 43,461,876 lire (£1,738,475), whereas some years previously the value of sulphur exported had hardly been 20,000,000 lire (£800,000). Now nineteen-twentieths of the sulphur consumed in the world is drawn from Sicilian mines, while some 50,000 persons are employed in the extraction, manufacture, transport, and trade in the mineral.

Another Sicilian mineral industry is that of common salt and rock-salt. The former is distilled from sea-water near Trapani, and the latter obtained in smaller quantities from mines. The two branches of the industry yield about 180,000 tons per annum, worth 2,000,000 lire (£80,000). About half this quantity is exported, principally to Norway. Besides salt, the asphalt mining industry may be mentioned. Its centre is the province of Syracuse. The value of the annual output is about 1,000,000 lire (£40,000).

Fisheries.

Deep-sea fisheries give employment to some twenty thousand Sicilians, who exercise their calling not only off the coasts of their island, but along the north African shore, from Morocco to Tripoli. In 1894 (the last year for which accurate statistics have been issued) 350 fishing smacks were in active service, giving a catch of 2480 tons of fish. Approximately, the value of the annual catch may be reckoned at from 15 to 20 million lire (£600,000 to £800,000).

Industries.

The majority of the scanty Sicilian industries are directly connected with various branches of agriculture. Such, for instance, is the preparation of the elements of citric acid, which is manufactured at an establishment at Messina. Older and more flourishing is the Marsala industry. Marsala wine is a product of the western vineyards situated slightly above sea level. In 1899 more than 38,000 hectolitres were exported to the value of more than 3,000,000 lire (£120,000). The quantity consumed in Italy is far greater than that exported.

Another flourishing Sicilian industry carried on by a large number of small houses is that of preserving vegetables in tins. Artichokes and tomato sauce are the principal of these products, of which several dozen million tins are annually exported from Sicily to the Italian mainland, to Germany, and to South America. Manufactories of furniture, carriages, gloves, and leather exist in large number in the island. They are, as a rule, small in extent, and are managed by the owners with the help of five, ten, or at most twenty workmen. Within the last decade several glass works have been established at Palermo, a match factory at Caltanissetta, a cotton dyeing works at Messina, and a large metal foundry at Palermo. Large shipbuilding yards and a yard for the construction of trams and railway carriages are now being laid out in the latter city.

Ways of communication.

Naturally Sicilian trade is almost all sea-borne. The ports of Palermo and Messina register a gross traffic of over three million tons annually. Prior to 1860 there was not a single kilometre of railway in Sicily. The total length of Sicilian railways is now 1000 miles. Their construction was rendered very costly by the mountainous character of the island. Traffic returns on the whole are not high, but are steadily increasing.

Like all southern Italy, Sicily in 1860 was poor, notwithstanding the possession of notable reserves of monetary capital. On the completion of Italian unity part of this pecuniary capital was absorbed by the sudden increase of taxation, and a much greater part was employed by private individuals in the purchase of lands formerly belonging to the suppressed religious corporations. These lands covered about one-fifth of the surface of the island. Both the revenue acquired by taxation and the proceeds of the land sales were almost entirely spent by the State in northern Italy, where the new Government, for administrative and military reasons, had been obliged to establish its principal organizations, and consequently its great centres of economic consumption. It was therefore necessary to meet from scanty local revenues the continually-increasing expenditure necessary for public instruction, ways of communication, hygienic improvements, and, generally, for introducing modern European civilization among a people who until then had lived penuriously, ignorant of many needs, consuming little, and resembling in many respects an Oriental population. Thus it is easy to understand that while in some respects the island has made rapid progress and the large cities have been beautified and developed, in other respects it remains in a backward state, many communes of the *latifondi* zone being still in the moral and material conditions of a century ago. As a general rule, trade and the increase of production have not kept pace with the development of the ways of communication.

Economic, intellectual, and moral conditions of the population.

The poverty of the Sicilian population is accentuated by the unequal distribution of wealth among the different classes of society. A small but comparatively wealthy class—composed principally of the owners of *latifondi*, who are not invariably descended from the barons of former times—resides habitually in the large cities of the island, or even at Naples, Rome, or Paris. Yet even if all the wealthy landowners resided on their estates, their number would not be sufficient to enable them to play in local public life a part corresponding to that of the English gentry. On the other hand, the class which would elsewhere be called the middle class is in Sicily extremely poor. The origin of most of the abuses which vitiate Sicilian political life, and of the frequent scandals in the representative local administrations, is to be found in the straitened condition of the Sicilian middle classes. The artisan class in the cities is not appreciably poorer than in other parts of Italy. The condition of the peasant in the zone of intensive culture is also bearable, many of the peasants being themselves small proprietors. The peasants of the *latifondi* zone, on the contrary, are as a rule poverty-stricken.

Emigration, which might improve the condition of the agricultural proletariat, only attained serious proportions within the last decade of the 19th century. In 1897 the permanent emigation from the island was 15,994, in 1898, 21,320, and in 1899, 24,604.

Emigration.

The moral and intellectual defects of Sicilian society are in part results of the economic difficulties above described, and in part the effect of bad customs introduced or maintained during the long period of Sicilian isolation from the rest of Europe. When, in 1860, Sicily was incorporated in the Italian kingdom, hardly a tenth of the population could read and write. Upon the completion of unity, elementary schools were founded everywhere; but, though education was free, the indigence of the peasants in some regions prevented them from taking full advantage of the opportunities offered. Thus, even now, nearly 60 per cent. of the Sicilian conscripts come up for military service unable either to read or to write. Secondary and superior education is much more diffused, and Sicily perhaps furnishes more students to the lycées and universities in proportion to population than any part of Italy.

Public instruction.

Brigandage of the classical type has almost disappeared from Italy. The true brigands number hardly more than a dozen, and haunt only the most remote and most inaccessible mountains. Criminal statistics, though slowly diminishing, are still high—murders, which are the most frequent crimes, having been 27 per 100,000 inhabitants in 1897–98. Violent assaults with infliction of serious wounds are also frequent. While explicable in part by the violent temperament of the Sicilians and in part by the insufficiency and incapacity of the police, this readiness to commit bloodshed is still more attributable to the influence of the Maffia. The Maffia is not, as is generally believed, one vast society of criminals, but is rather a sentiment akin to arrogance which imposes a special line of conduct upon persons affected by it. In substance the *maffioso* considers it dishonourable to have recourse to lawful authority to obtain redress for a wrong or a crime committed against him. He therefore hides the identity of the offender from the police, reserving vengeance to himself or to his friends and dependants. This sentiment, still widely diffused among the lower classes of many districts and not entirely unknown to the upper classes, renders difficult legal proof of culpability for acts of violence, and multiplies sanguinary private reprisals.

Brigandage and Maffia.

The nature of Sicilian moral sentiment explains the elevated standard of family life, the small number of illegitimate births, the respect for women even among the lowest classes (the assertions of superficial observers notwithstanding), the scrupulous fidelity with which a Sicilian workman executes his task, and the discipline and bravery of Sicilian soldiers and sailors—attributable to their personal devotion towards their officers. If to these qualities be added an almost universal industry, a certain spirit of dignity, order and thrift in all classes, and, finally, the general sobriety of the population (drunkenness is practically unknown in the island), it will be seen that elements exist by means of which Sicily may in time become a prosperous and morally elevated country when Italy, which has already passed through the laborious period which followed her national unification, shall have completed that work of economic and moral restoration which may already be considered as well begun. (G. Mo.)

The family.

Sidgwick, Henry (1838–1900), English philosopher, born at Skipton, in Yorkshire, on 31st May 1838, was educated at Rugby and Cambridge, where his career was a brilliant one. In 1859 he was senior classic, 33rd wrangler, and Chancellor's medallist. In the same year he was elected to a fellowship at Trinity, and soon afterwards appointed to a classical lectureship there. This post he held for ten years, but in 1869 exchanged his lectureship for one in moral philosophy, a subject to which he had been turning his attention more and more. In the same year he resigned his fellowship on conscientious grounds, when the question of the abolition of religious tests for fellowships was being pressed, a reform actually carried two years later. In 1874 Sidgwick published his *Method of Ethics*, which first won him a reputation outside his university. In 1875 he was appointed prælector on moral and political philosophy at Trinity, in 1883 he was elected Knightbridge professor of moral philosophy, and in 1885 his college once more elected him to a fellowship. In 1883 he published the *Principles of Political Economy*; in 1885 the *Scope and Method of Economic Science*; in 1886 *Outlines of the History of Ethics*, enlarged from the article "Ethics" in the *Encyclopædia Britannica*; and in 1891 the *Elements of Politics*, intended to supply the want of an adequate treatise on the subject by starting from the old lines of Bentham and Mill. Besides his lecturing and literary labours, Sidgwick took an active part in the business of the university, and in many forms of social and philanthropic work. He was a member of the General Board of Studies from its foundation in 1882 till 1899; he was also a member of the Council of the Senate of the Indian Civil Service Board and the Local Examinations and Lectures Syndicate, and chairman of the Special Board for Moral Science. He was one of the founders of the Society for Psychical Research and of the Metaphysical Society. None of his work is more closely identified with his name than the part he took in promoting the higher education of women. He helped to start the higher local examinations for women, and the lectures held at Cambridge in preparation for these. It was at his suggestion and with his help that Miss Clough opened a house of residence for students; and when this had developed into Newnham College, and in 1880 the North Hall was added, Mr Sidgwick, who had in 1876 married Miss Eleanor Mildred Balfour, went with his wife to live there for two years. After Miss Clough's death in 1892, Mrs Sidgwick became principal of the college, and she and her husband resided there for the rest of his life. During this whole period Professor Sidgwick took the deepest interest in the welfare of the college. Early in 1900 he was forced by ill-health to resign his professorship, and he died in August of the same year. (See Ethics.) (A. Z.)

Sidmouth, a watering-place and market town in the Honiton parliamentary division of Devonshire,

England, pleasantly situated at the mouth of the Sid, 15 miles by rail east by south of Exeter. The harbour is inaccessible for vessels over 200 tons. The church of St Nicholas contains a window, presented by Queen Victoria, 1866, in memory of the duke of Kent, who died here. There is a Roman Catholic convent, and public edifices are the market buildings, a Masonic hall, a volunteer drill-hall, public baths, a promenade sea-wall, and a cottage hospital. Area of parish (an urban district) prior to extension in 1899, 1563 acres. Population (1891), 3758; (1901), 4201.

Sidney, a city of Ohio, U.S.A., capital of Shelby county. It is on the river Miami, the Miami and Erie canal, and the Cleveland, Cincinnati, Chicago, and St Louis and the Cincinnati, Hamilton, and Dayton railways, in the western part of the state. Population (1890), 4850; (1900), 5688, of whom 282 were foreign-born and 108 negroes.

Sidon (now *Saidá*), a small town on the Syrian coast between Beirût and Súr (Tyre). The population is 11,000 (Moslems 8000, Christians 2500, Jews 500). The exports comprise olive oil and fruit, especially oranges and lemons. In 1887 tomb chambers were discovered close to the town, which contained several fine Greek and Phœnician sarcophagi, including the "Alexander" sarcophagus, a unique work of art in the form of a Greek temple, and the sarcophagus of Tabnith, king of Sidon. These sarcophagi are now in the Imperial Museum at Constantinople. Remains have been found of a building which apparently belongs to the Persian period.

Siedlce (Russian, *Syedlets*), a government of Russia in the east of Poland, with an area of 5535 square miles and a population which was 630,240 in 1884 and 775,316 (census population, domiciled only) in 1897, when there were 382,896 women and the urban population numbered 110,995. The inhabitants are chiefly Little Russians (43 per cent.), Poles (40 per cent.), Jews (15 per cent.), and Germans. The government is divided into nine districts, the chief towns of which are the capital, Siedlce (23,714 inhabitants), Biała (13,123), Konstantinow (1840), Garwolin (5554), Łukow (8317), Radzyn (5718), Sokołow (7246), Węgrow (8679), Włodawa (6758). The main occupation is still agriculture; 1,035,300 acres were under crops in 1900, and the average yield in 1895–99 was: rye 3,086,000 cwt., wheat 730,000 cwt., oats 1,485,600 cwt., barley 436,500 cwt.—all cereals, 6,198,000 cwt.; also potatoes, 10,280,000 cwt., they being largely grown for distilleries. The area under forests in 1898 was 97,300 acres. Cattle-breeding is second in importance only to agriculture; in 1897 there were 84,250 horses, 323,240 horned cattle, 341,640 sheep, and 165,450 pigs. Manufactures and trade are insignificant.

Siegburg, a town of Prussia, in the Rhine province, on the river Sieg, 16 miles by rail south-east of Cologne. It has a royal projectile factory, calico-printing mills, lignite mines, stone quarries, and tobacco factories. The parish church, dating from the 13th century, possesses several richly-decorated reliquaries of the 12th to 15th centuries. A former Benedictine abbey, founded in 1066, is now used as a prison. Population (1885), 7514; (1900), 14,164.

Siegen, a town of Prussia, province of Westphalia, 63 miles by rail east of Cologne. It is the centre of the iron-mining, iron-smelting, and tanning industries of southern Westphalia. In the town are two castles of the former princes and counts of Nassau-Siegen, and an equestrian statue of the Emperor William I. Population (1885), 16,676; (1900), 22,111.

Siemens, Ernst Werner von (1816–1892), German electrician, was born on the 13th December 1816 at Lenthe, in Hanover. After attending the gymnasium at Lübeck, he entered the Prussian army as a volunteer, and for three years was a pupil in the Military Academy at Berlin. In 1838 he received a commission as lieutenant in the artillery, and six years later he was appointed to the responsible post of superintendent of the artillery workshops. In 1848 he had the task of protecting the port of Kiel against the Danish fleet, and as commandant of Friedrichsort built the fortifications for the defence of Eckernförde harbour. In the same year he was entrusted with the laying of the first telegraph line in Germany, that between Berlin and Frankfort-on-Main, and with that work his military career came to an end. Thenceforward he devoted his energies to furthering the interests of the newly-founded firm of Siemens and Halske, which under his guidance became one of the most important electrical undertakings in the world, with branches in different countries that gave it an international influence; in the London house he was associated with Sir Charles Siemens, one of his younger brothers. Although he had a decided predilection for pure research, his scientific work was naturally determined to a large extent by the demands of his business, and, as he said when he was admitted to the Berlin Academy of Sciences in 1874, the filling up of scientific voids presented itself to him as a technical necessity. Considering that his entrance into commercial life was almost synchronous with the introduction of electric telegraphy into Germany, it is not surprising that many of his inventions and discoveries relate to telegraphic apparatus. In 1847, when he was a member of the committee appointed to consider the adoption of the electric telegraph by the Government, he suggested the use of gutta-percha as a material for insulating metallic conductors. Then he investigated the electrostatic charges of telegraph conductors and their laws, and established methods for testing underground and submarine cables and for locating faults in their insulation; further, he carried out observations and experiments on electrostatic induction and the retardation it produced in the speed of the current. He also devised apparatus for duplex and diplex telegraphy, and automatic recorders. In a somewhat less specialized sphere, he was an early advocate of the desirability of establishing some easily reproducible basis for the measurement of electrical resistance, and suggested that the unit should be taken as the resistance of a column of pure mercury one metre high and one square millimetre in cross-section, at a temperature of 0° C. Another task to which he devoted much time was the construction of a selenium photometer, depending on the property possessed by that substance of changing its electrical resistance according to the intensity of the light falling upon it. He also claimed to have been, in 1866, the discoverer of the principle of self-excitation in dynamo-electric machines, in which the residual magnetism of the iron of the electro-magnets is utilized for excitation, without the aid of permanent steel magnets or of a separate exciting current. In another branch of science he wrote several papers on meteorological subjects, discussing among other things the causation of the winds and the forces which produce, maintain, and retard the motions of the air. In 1866 he devoted half a million marks to the foundation of an imperial institute of technology and physics, and in 1888 he was ennobled. He died at Berlin on the 6th of December 1892. His scientific memoirs and addresses were collected and published in an English translation in 1892, and three years later a second volume appeared containing his technical papers. (H. M. R.)

Siemrat, or SIEMRAP, one of the south-eastern provinces of Siam, situated at the north end of the Talé Sap, the lake of Cambodia. The total population cannot exceed 10,000, and consists mostly of Cambodians and descendants of former Siamese garrisons, who have adopted that language. Agriculture and fishing are the chief pursuits of the people. The trade is very small; the sandy soil produces a red-grained rice which has not a good reputation for quality. Close by the chief town—a mere village of some 2000 inhabitants—there are the remains of the old brick kampeng, or fort, erected by Praya Bodin after the capture of this province from the Cambodians in the 18th century. But Siemrat is best known for the great ruins of Angkor, or Nakawn, Wat, which stand a mile or two to the northward buried in dense forest, an unending source of awe and mystery to the native and of admiration to the European visitor. These, with the extensive remains of Nakawn Luang, the old city close by, form remarkable relics of the architectural genius of the Khmer race, which between the 8th and 12th centuries had spread itself from the sea to Korat and the Me Kong.

Siena, a town and archiepiscopal see of Italy, Tuscany, capital of the province of Siena, 61 miles by rail south of Florence. The Victor Emmanuel hall in the town hall, adorned by frescoes by the Sienese artists Aldi, Cassioli, and Maccari, was opened in 1891. In 1882 some frescoes by Pinturicchio were discovered in an apartment of the palace which was built for Pandolfo Petrucci in 1508. The church of San Francesco was finally restored in 1885–92. The university was attended by 231 students in 1898, and there were 31 professors. Siena is a place of some industrial activity, and possesses a school of the industrial arts and sciences. Population (1881), 23,445; (1901), 28,678.

Siero, a town of Spain, in the province of Oviedo, to the south of Gijon, on the river Nora, and on the Laviana–Gijon and Leon–Gijon railways. It is in the centre of a fertile agricultural district, in which live stock is extensively reared. There are coal mines in the neighbourhood, and the local industries include tanning and manufactures of soap, coarse linen, and cloths. Population (1897), 22,456.

Sierra Leone, a British colony on the west coast of Africa. Sierra Leone proper consists of a peninsula, about 26 miles in length to Cape Shilling, by about 12 in breadth, with an area of about 300 square miles. The colony, as distinct from the protectorate, now takes in the entire seaboard southwards to the Mano river, which forms the Liberian boundary, including Sherbro Island, Banana, Turtle, Plantain, and other minor islands· also Turner's peninsula, a narrow strip of land from Bahol, Shea Bar, extending in a south-east direction about 60 miles to the Kase Lake and lying between the Bum Kittam river and the North Atlantic—thence the coast is continued to the ports of Sulima and Mano Salija, Garinga, about 8 miles up the Mano river, being the extreme limit of the colony proper. Northwards, the Isles de Los, Yellaboi, Kortimo, and Leopard Islands, and other small islets are also included. There is no further room for extension, the whole being hemmed in—one-third by the North Atlantic, one-third by French territory, and the remaining one-third by Liberia.

In 1896 the entire area beyond the colony proper, containing about 30,000 square miles, now described as the protectorate, was proclaimed as such, and was divided into five sections or districts, each under a European commissioner, namely, Ronietta, Karene, Bandajuma, Panguma, and Koinadugu. The protectorate extends on the northern coast-side of the colony to Kiragba, between the Great Scarcies river and the Mellacouri river, and then follows the defined Anglo-French and Anglo-Liberian delimitations. Upon first acquaintance it is difficult to realize that a country presenting such naturally beautiful surroundings can have a climate which is so deadly to the European. Gambia was administratively separated from Sierra Leone in 1888, so that Sierra Leone now stands alone as a distinct government. After 1875 a complete transformation took place in the geographical disposition of the British sphere of influence, in the delimitation of British territory by the various boundary commissions, and in the introduction of a governmental interior policy which has led to the protectorate being proclaimed, with a population estimated at about 1,000,000.

Freetown.

Freetown, the capital, which has a reputed population of about 30,000 inhabitants, mostly negroes, has come into greater prominence from its having been made a coaling station of the Imperial Government, the natural open roadstead, 5 miles from the Cape, being capable of receiving the largest ships of war, and is the finest and safest harbour on the west coast of Africa. Freetown is the headquarters of His Majesty's military forces on this coast, the barracks being at Tower Hill, Kortright Hill, Mount Oriel, and Wilberforce. The forces consist of a battalion of the West India regiment, detachments of Royal Engineers and Royal Artillery, and in 1898 was raised the West African regiment from local native tribes, commanded by Imperial European officers. For the protectorate there are the frontier police, a native colonial force numbering 600, under European military officers; and for the colony proper there are the Sierra Leone police, about 270 strong, under a European superintendent and inspector, for the performance of civil duties. There has been cable communication from Freetown to all parts of the world since 1886, and sea communication is weekly by mail steamers from Liverpool, supplemented by frequent steamers from Hamburg. A Government light railway was begun at Freetown in 1897, and the first section, costing £150,000, as far as Songo Town, a distance of 30 miles, was opened for traffic early in 1899; it passes through the villages of Kissi, Wellington, Hastings, Waterloo, and Newton, the journey occupying 3 hours 20 minutes. The railway has been continued across the Ribbi river to Moyamba, 45 miles; and it is contemplated to advance a considerable way into the interior, where the heavier natural productions will be met with, which should yield a revenue for the maintenance of the line.

Commercially, Freetown is a great trading centre and depot for supplying the rivers; it produces nothing in the way of exports; the villages around cultivate ginger, coffee, fruits, vegetables, cassada, and Indian corn, and raise poultry, all of which articles find a ready market in the capital. The exports comprise palm oil, palm kernels, kola nuts, peppers, benni seed, all from the Sherbro district and the protectorate, which also produce rice.

Freetown is noted for the abundance and excellence of its water, which comes down from the hills; but the sanitation of the town calls for great improvement, and the lighting remains surprisingly behind the times, kerosene lamps being still in use in the streets. Horses do not live, consequently all wheeled traffic is drawn by manual labour—hammocks and sedan-chairs are the customary means of locomotion. The principal buildings in the town are the cathedral, the Wilberforce Hall, the fruit market, the railway station, the model school, the courts of justice, the post office, the hospital, the Government buildings, and the gaol. Outside the town are the Princess Christian Hospital, Bishop's Court, Fura Bay College, and the railway depot at Clinestown.

Statistics of Sierra Leone.

According to the census returns of 1891, the whole population in the colony proper, *i.e.*, at places indicated in the following table, was:—

	White.		Coloured Population.		Total.	
	Males.	Females.	Males.	Females.	Males.	Females.
Freetown District:						
St George's Parish	169	30	16,142	13,602	16,311	13,722
Eastern Division	..	..	2,100	2,113	2,100	2,113
Mountain Division	2	2	3,082	2,994	3,084	2,996
Western District	..	..	2,876	2,565	2,876	2,565
Eastern District	1	..	6,494	6,186	6,495	6,186
Sherbro	19	1	7,324	6,164	7,343	6,165
The Isles de Los	..	..	814	764	814	764
Kaikonki	..	..	71	19	71	19
Factories (Govt.) in S.L. River	..	..	26	9	26	9
Tasso	..	..	680	360	680	360
Sulima Sub-District	..	..	..	..	..	..
	191	33	39,609	34,866	39,800	34,899

The total population was thus 74,699. The white population, owing to the influx of numerous military officers, officials for the protectorate, and extended mercantile operations, has greatly increased. The dangers of the climate on the coast from malaria and fever remain unabated, and the colony justly retains its evil reputation: 40 or 50 miles inland, the country is much healthier, and is tolerable for Europeans; but the isolated life they are compelled to lead, surrounded by savagery, is prejudicial to any lengthened residence.

The rainfall of Sierra Leone, according to the colonial hospital observations at Freetown for three years, was as follows:—1896, 203 inches; 1897, 164 inches; 1899, 144 inches. The months of January, February, and March are practically rainless near the coast; desultory showers occur in April to the early part of May; towards the end of that month the wet season sets in, and continues until the end of October. With November the rain is again desultory, gradually ceasing with December. Tornadoes open and close the seasons, which is considered the unhealthiest time, the best time being the middle of the rains or "dries." The Harmattan wind, known as "the smokes," comes in with December, and lasts from two to three months—generally daily, from early morning to noon. This is a north-east dry and desiccating wind, making the atmosphere cool and invigorating, though treacherous to the newcomer.

The following figures show the value of the principal exports for the four years enumerated:—

	Benni Seed.	Kola Nuts.	Ginger.	Hides.	Palm Kernels.	Palm Oil.	Rubber.	Gum Copal.
	£	£	£	£	£	£	£	£
1896 . .	12,577	38,352	14,145	13,641	151,846	17,546	79,196	12,258
1897 . .	7,555	46,552	13,506	5,030	120,910	9,149	79,787	13,142
1898 . .	5,260	49,670	11,935	602	112,003	3,405	52,504	9,058
1900 . .	4,559	79,218	6,233	501	171,774	7,436	25,740	6,953

From these figures it will be seen that there was a falling off in everything except kola nuts, which, however, are chiefly exported to Gambia and to Senegal, and in palm kernels; the cultivation of ground nuts, which was formerly one of the large exports, has been superseded by exports from India. On their extinction rubber was discovered, and has continued to be worked, most of it coming from the northern side. The vine is plentiful in Upper Mendi, but as yet the Mendis have not given it much attention.

History. Before the rising of the natives in 1898, the whole country had been in a particularly tranquil state since 1890, when the Government adopted a firm and greatly extended policy for the interior, it having been obvious for some time previously that the internecine wars which devastated and depopulated large areas, and were of constant recurrence, greatly hindered the prosperity of the colony. Travelling commissioners were appointed to explore the hinterland, and to enter into friendly treaties with the paramount chiefs; and the frontier police were organized. The abolition of slavery followed; and with the introduction of the Protectorate Ordinance in 1897, a house tax of 5s. each was imposed, to come into operation in the three first-named districts on the 1st January 1898. Chief Bai Burch, in the Timini country, broke out into open war, necessitating a military punitive expedition. He was at length captured, and deported. In April 1898 the Mendi tribes rose, and massacred several American missionaries at Rotifunk and Taiama, some native officials in the Imperri district, and a large number of police throughout the country. Speedy retribution followed, which effectually put down the revolt. A Royal Commission was appointed to inquire into the disturbances, which resulted in a continuance of the house tax. The disturbances would appear to have arisen from a desire on the part of the paramount chiefs (who arranged and disseminated a powerful fetich "swear," called "Poro," to compel the people to join) to cast themselves off from British rule, owing to the abolition of the slave trade and a longing to revert to their old heathenish customs and practices.

The principal port for the shipping of the largest item of export—palm kernels—is Sherbro, lying about 90 miles to the south-east of Sierra Leone. Bonthe is the seat of government, situated upon Sherbro Island.

Commerce. The channel for ocean steamers has been buoyed by the Government at considerable expense. Sherbro is now producing a revenue of over £30,000 a year. The total quantity of kernels shipped in 1899-1901 from Sherbro averaged about 13,456 tons a year. The oil palms, from which the nuts are gathered twice a year, extend all over Sherbro and its hinterland, the Mendi country, and are practically unlimited, the production being entirely Nature's work, as the natives never plant them.

Sherbro and Mendi produce large quantities of kola nuts and rice, and, in smaller quantities, benni seed, pepper, piassava, and rubber. Cotton for local consumption is extensively grown. It is from the Sherbro side of the colony that the heavy natural productions are obtained and exported; but there is much scope for far greater export, when the great barrier to the development of the hinterland—the overland transport difficulty—shall have been overcome; at present all inland produce is brought down, in palm-leaf hampers upon the backs of native carriers, to some riverside trading factory, whence it is conveyed in canoes and lighters to the port of Sherbro for shipment to the ocean steamers, the anchorages being off the Bonthe channel and off York Island.

So far as salt water extends, the banks of the waterways are covered by mangrove trees, the haunts of crocodiles, but with fresh water the vegetation becomes mixed and of the usual tropical descriptions. The system of barter still prevails, though it is not so universal as formerly; the stationing of Imperial troops and colonial police in the protectorate is causing a great deal of British coin to be circulated, which is much appreciated by the natives. The country generally is plentifully watered, many places which in the "dries" are mere streams and rivulets, to be stepped over, become in the rains so swollen as to be unfordable; hence the difficulty of interior travelling during the wet season.

The total shipping entered and cleared for four years is as follows: 1897, 1,084,745 tons; 1898, 1,110,228 tons; 1899, 1,681,748 tons; 1900, 1,290,933 tons; about three-fourths British. The revenue of the colony was as follows: 1888, £63,035; 1897, £107,033; 1898, £117,682; 1900, £168,668; and the expenditure for corresponding years: 1888, £63,288; 1897, £111,678; 1898, £121,112; 1900, £156,421. The total imports: 1888, £250,147; 1897, £457,389; 1898, £606,349; 1900, £558,271. Total exports: 1888, £339,047; 1897, £400,748; 1898, £290,991; 1900, £362,471.

Sifan. See LOLOS.

Sigmaringen, a town of Prussia, chief town of the province of Hohenzollern, on the right bank of the upper Danube, 55 miles by rail south of Tübingen. The castle of the Hohenzollerns crowns a high rock above the river, and contains a collection of pictures, an exceptionally interesting museum (textiles, enamels, metal-work, &c.), an armoury, and a library. On the opposite bank of the Danube there is a war monument to the Hohenzollern men who fell in 1866 and 1870–71. Population (1900), 4576.

Signals (Army).—There are two systems of signalling in use in the British army, (1) the Morse (or dot

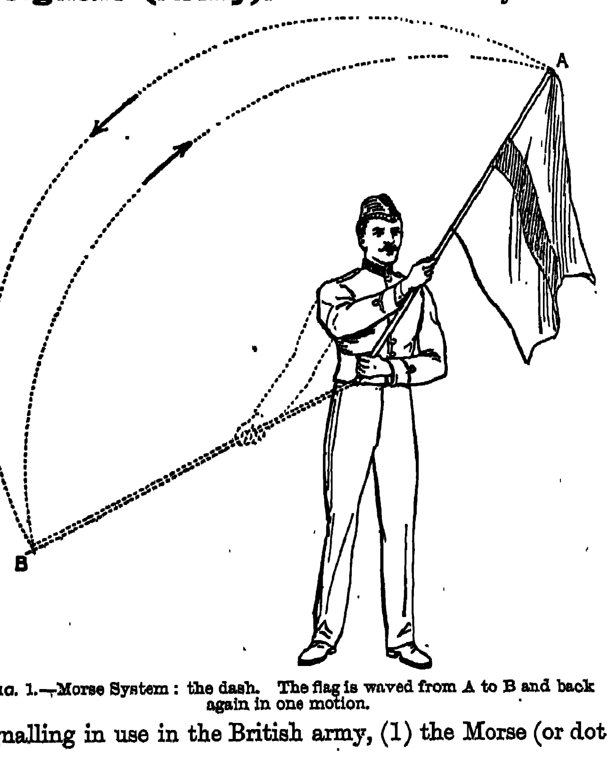

FIG. 1.—Morse System: the dash. The flag is waved from A to B and back again in one motion.

and dash, Figs. 1, 2), (2), the semaphore (Figs. 3, 4). The first is the more generally used, and is also employed in telegraphy and naval signalling. It is carried on by means of a flag or heliograph by day, and lamps by night. The flag is either dark blue or white with a horizontal line, according to the background. It is made in two sizes, the larger having drapery 3 feet square with a pole 5 feet 6 inches in length, the smaller 2 feet square of drapery and a 3 feet 6 inch pole. The former is visible with an ordinary telescope from 5 to 7 miles, but with a good glass can

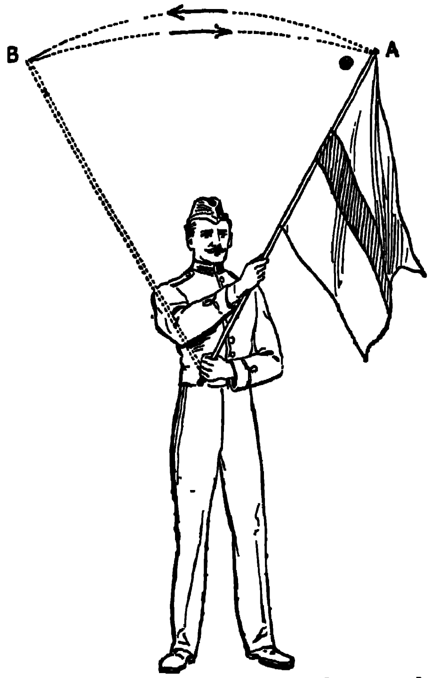

FIG. 2.—Morse System: the dot. The flag is waved from A to B and back again in one motion.

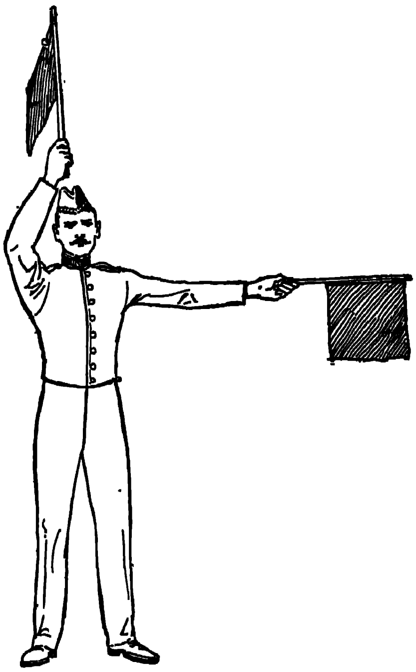

FIG. 3.—Semaphore System: letter J.

be seen at a much greater distance. The latter under similar conditions is visible from 3 to 4 miles. To form the dot and dash the flag is waved in a short or long arc, the latter being regulated to three times the length of the former. The heliograph, as its name implies, can only be used in conjunction with the sun (Figs. 5, 6). It consists of a circular movable mirror, generally 5 inches or 3 inches in diameter, so arranged that it may reflect the rays of the sun on and off a distant station. The dot and dash are formed by the length of time the rays are allowed to

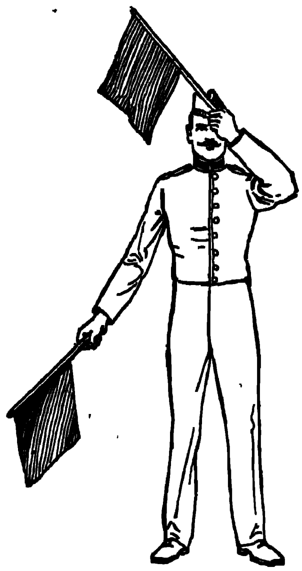

FIG. 4.—Semaphore System: letter I.

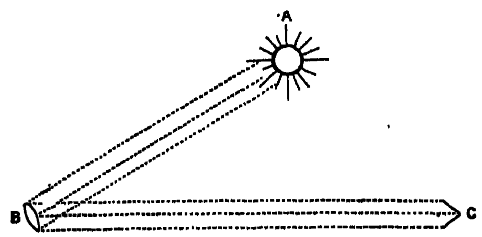

FIG. 5.—The Heliograph. A, the sun; B, signalling mirror; C, distant station.

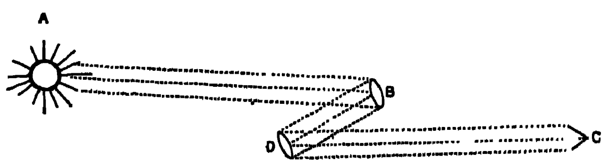

FIG. 6.—The Heliograph. A, the sun; B, signalling mirror; C, distant station; D, duplex mirror.

remain on the station. When the sun makes an angle of more than 120 degrees with the mirror and the station, a duplex mirror is employed, the sun rays being collected on the signalling mirror, thence reflected on to the duplex mirror, and from there again to the station required. Three kinds of lamp are used for signalling by night:—(1) the ordinary hand-lamp, which is an enlarged bull's eye burning colza or other vegetable oil, with a shutter for exposing and obscuring the light, visible 3 to 4 miles; (2) the Begbie, made in three sizes, burning kerosene oil and visible with glasses 10, 20, and 40 miles respectively—these are principally used in India; (3) the limelight

apparatus, visible 10 to 15 miles or more according to atmospheric conditions. The semaphore system is used for comparatively short distances. It is simpler and more rapid than the Morse system, but is only adapted for use during the day. Two small flags are employed, and the letters of the alphabet are formed by the positions in which they are held.

In every regiment of cavalry on the higher establishment there are 4 signallers per squadron; those on the lower establishment, household regiments, and regiments abroad, have 3 per squadron; and there are at least 2 supernumeraries per service squadron. In the royal garrison artillery there are 4 signallers per company, and 3 per mountain battery. In the infantry there are 6 signallers per battalion, and at least 1 supernumerary per company. In addition to the above, 1 officer is appointed as instructor and 1 non-commissioned officer as assistant-instructor, both of whom should hold certificates from one of the schools of instruction. Signallers are inspected annually, and are required to send, transmit, and read messages accurately at a rate of not less than 6 words a minute. Those who qualify receive 15s. each and the right to wear a badge until the following year's inspection. Signallers employed in the field may be combined to form either brigade or special signalling companies. The former consist of men drawn from regiments on the spot, and may contain any available number under an officer. A special signalling company is an independent unit of an army corps; it may be mounted or dismounted, and the signallers are taken from regiments not in the field.

Signalling is used on most campaigns to a large extent. In the Tirah expedition, 1897 and 1898, one signal station received and sent, between the 1st and 18th November, as many as 980 messages by heliograph, some of which were 200 to 300 words in length. It is often used as an auxiliary to the field telegraph, especially in mountainous countries, and when the wire is liable to be cut and stolen by hostile natives. In the Waziri expedition, 1881, communication was maintained direct for a distance of 70 miles with a 5-inch heliograph. In the Boer war, 1899–1902, the system of heliographic signalling was employed very extensively by both sides.

The electric search-light is occasionally used for signalling purposes; and when the intervening ground intercepts the light, the rays are projected on to a cloud, and thence read by the distant station. (G. A. BR.)

Signals (Naval).—A system of naval signals comprises different methods of conveying orders or information between ships or with the shore by signs. In the British navy, which serves as a model to most others, visual signals are made with flags or pendants, the semaphore, flashing, and occasionally fireworks. Sound signals are made with fog-horns, steam-whistles, sirens, and guns. The number of flags in use in the naval code, comprising what is termed a "set," are 58, and consist of 26 alphabetical flags, 10 numeral flags, 16 pendants, and 6 special flags. Flag signals are divided into three classes, to each of which is allotted a separate book. One class consists of two alphabetical flags, and refers to orders usual in the administration of a squadron, such as, for example, the flags LE, which might signify "Captain repair on board flagship." Another class consists of three alphabetical flags, which refer to a coded dictionary, wherein are words and short sentences likely to be required. The remaining refers to evolutionary orders for manœuvring, which have alphabetical and numeral flags combined. The flags which constitute a signal are termed a "hoist." One or more hoists may be made at the same time. Although flag signalling is a slow method compared with others, a fair rate can be attained with practice. For example, a signal involving 162 separate hoists has been repeated at sight by 13 ships in company in 76 minutes. Semaphore signals are made by the extension of a man's arms through a vertical plane, the different symbols being distinguished by the relative positions of the arms, which are never less than 45° apart. To render the signals more conspicuous the signaller usually holds a small flag on a stick in each hand, but all ships are fitted with mechanical semaphores, which can be worked by one man, and are visible several miles. Flag signalling being comparatively slow and laborious, the ordinary message work in a squadron is generally signalled by semaphore. The convenience of this method is enormous, and by way of example it may be of interest to mention a record message of 350 words which was signalled to 21 ships simultaneously at the rate of 17 words per minute. Flags being limited in size, and only distinguishable by their colour, signals by this means are not altogether satisfactory at long distances, even when the wind is suitable. For signalling at long range the British navy employs a semaphore with arms from 9 to 12 feet long mounted at the top of the mast and capable of being trained in any required direction, and worked from the deck. Its range depends upon the clearness of the atmosphere, but instances are on record where a message by this means has been read at 16 to 18 miles.

Night signalling is carried out by means of "flashing," by which is meant the exposure and eclipse of a single light for short and long periods of time, representing the dots and dashes composing the required symbol. The dots and dashes can be made mechanically by an obscuring arrangement, or by electro-mechanical means where magnets do the work, or by simply switching on and off specially manufactured electric lamps. The ordinary rate of signalling by flashing is from 7 to 10 words per minute. In the British navy, as in the army, dots and dashes are short and long exposures of light; but with some nations the dots and dashes are short and long periods of darkness, the light punctuating the spaces between them. The British navy uses the European modification of the so-called Morse code used in telegraphy, but with special signs added suitable to their code. The introduction of the "dot and dash" system into the navy was entirely due to the perseverance of Vice-Admiral Colomb, who, in spite of great opposition, and even after it had once been condemned on its first trial at sea, carried it through with the greatest success. The value of this innovation made in 1867 may be gauged by the fact that now it is possible to handle a fleet with ease and safety in darkness and fog—a state of affairs which did not formerly exist. The simplicity of the dot and dash principle is its best feature. As the system only requires the exhibition of two elements it may be used in a variety of different manners with a minimum of material, namely, by waving the most conspicuous object at hand through short and long arcs, by exhibiting two different shapes, each representing one of the elements, or dipping a lantern in a bucket, and so on. Its adoption has not only contributed very materially to the increased efficiency of the British navy, but it has been made optional for use with the mercantile marine. Curiously enough, flashing is not to any great extent used in foreign navies, who rely more on some system of coloured lights at night. This system generally takes the form of four or five double-coloured lanterns, which are suspended from some part of the mast in a vertical line. Each lantern generally contains a red and a white lamp, either of which can be switched on. By a suitable keyboard on deck any combination of these coloured lanterns can be shown. The advantage of this system lies in the fact that each symbol is self-evident

in its entirety, and does not require an expert signalman to read it, as is the case with flashing, which is a progressive performance.

For long distances at night the search-light, or some other high power electric arc light, is utilized on the flashing system. Dots and dashes are then made either by flashing the light directly on the object, or else waving the beam up and down for short and long periods of time. Sometimes when a convenient cloud is available the reflection of the beam has been read for nearly 40 miles, with land intervening between the two ships. In a fog signals are made by the steam-whistle, fog-horn, siren, or by guns. Except for the latter method the dot and dash system is employed in a similar manner to flashing a light. Guns are sometimes used in a fog for signalling, the signification being determined by certain timed intervals between the discharges. The larger British ships are supplied with telegraph instruments for connexion with the shore, and heliographs are provided for land operations. Marine galvanometers are also provided, and can be used to communicate through submarine cables. To the various methods of naval signalling must be added Signor Marconi's system of wireless telegraphy, which in its application to ships at sea bids fair to solve some problems hitherto impracticable. (See TELEGRAPHY, WIRELESS.)

The international code of signals, for use between ships of all nations, is perhaps the best universal dictionary in existence. By its means mariners can talk with great ease without knowing a word of one another's language. By means of a few flags you can ask any question and make any answer. The number of international flags and pendants used with the international code is 27, consisting of a complete alphabet and a special pendant characteristic of the code. At night flashing may be used. (A. F. E.)

Sigurðsson, Jón (1811–1879), Icelandic statesman and man of letters, was born in the west of Iceland in 1811. He came of an old family, and received an excellent education. In 1830 he was secretary to the bishop of Iceland, the learned Steingrímr Jónsson. In 1833 he went to the university of Copenhagen and devoted himself to the study of Icelandic history and literature. His name soon became prominent in the learned world, and it may safely be said that most of his historical works and his editions of Icelandic classics have never been surpassed for acute criticism and minute painstaking. Of these we may mention *Lögsögumannatal og Lögmanna á Islandi* ("Speakers of the Law and Law-men in Iceland"); his edition of *Landnáma* and other sagas in *Islendinga Sögur*, i.–ii. (Copenhagen, 1843–47); the large collection of Icelandic laws edited by him and Oddgeir Stephensen; and last, not least, the *Diplomatarium Islandicum*, which after his death was continued by others. But although he was one of the greatest scholars Iceland has produced, he was still greater as a politician. The Danish rule had, during the centuries following the Reformation, gradually brought Iceland to the verge of economic ruin; the ancient Parliament of the island, which had degenerated to a mere shadow, had been abolished in 1800; all the revenue of Iceland went into the Danish treasury, and only very small sums were spent for the good of the island; but worst of all was the notorious monopoly which gave away the whole trade of Iceland to a single Danish trading company. This monopoly had been abolished in 1787, and the trade had been declared free to all Danish subjects, but practically the old arrangement was continued under disguised forms. Jón Sigurðsson began a hard struggle against the Danish Government to obtain a reform. In 1854 the trade of Iceland was declared free to all nations. In 1840 the Althing was re-established as an advisory, not as a legislative body. But when Denmark got a free constitution in 1848, which had no legal validity in Iceland, the island felt justified in demanding full home rule. To this the Danish Government was vehemently opposed; it convoked an Icelandic National Assembly in 1851, and brought before that body a Bill granting Iceland small local liberties, but practically incorporating Iceland in Denmark. This Bill was indignantly rejected, and, instigated by Jón Sigurðsson, another was demanded of far more liberal tendencies. The Danish governor-general then dissolved the assembly, but Jón Sigurðsson and all the members with him protested to the king against these unlawful proceedings. The struggle continued with great bitterness on both sides, but gradually the Danish Government was forced to grant many important reforms. High schools were established at Reykjavik, and efforts made to better the trade and farming of the country. In 1871 the Danish Parliament (Riksdag) passed a law defining the political position of Iceland in the Danish monarchy, which, though never recognized as valid by the Icelanders, became *de facto* the base of the political relations of Iceland and Denmark. At last, in 1874, when King Christian IX. visited Iceland at the festival commemorating the millenary of the colonization of Iceland from Norway, he gave to the country a Constitution, with full home rule in all internal matters. An immense victory was gained, entirely due to Jón Sigurðsson, whose high personal qualities had rallied all the nation round him. He was a man of fine appearance, with an eloquence and diplomatic gifts such as no others of his countrymen possessed, and his unselfish love of his country made itself felt in almost every branch of Icelandic life. Recognizing the value of an intellectual centre, he made Reykjavik not only the political, but the spiritual capital of Iceland by removing all the chief institutions of learning to that city; he was the soul of many literary and political societies, and the chief editor of the *Ny Félagsrit*, which has done more than any other Icelandic periodical to promote the cause of civilization and progress in Iceland. After Iceland had got home rule in 1874, the grateful people showered on Jón Sigurðsson all the honours it could bestow. He lived the greater part of his life in Copenhagen, and died there in 1879; but his body, together with that of his wife, Ingibjörg Einarsdóttir, whom he had married in 1845, and who survived him only a few days, was taken to Reykjavik and given a public funeral. On his monument was placed the inscription: "The beloved son of Iceland, her honour, sword, and shield." (S. BL.)

Sikkim, called by Tibetans, Dejong (the rice country), a protected state of India, situated in the eastern Himalaya, between 27° 5′ and 28° 10′ N. and between 88° 4′ and 88° 58′ E. It comprises an area of 2818 square miles of what may be briefly described as the catchment basin of the headwaters of the rivers Tista and Rungit. On the S. and S.E., branches of these rivers form the boundary between Sikkim and British India, while on the W., N., and N.E. Sikkim is separated from Nepal, Tibet, and Bhutan by the range of lofty mountains, which culminate in Kanchinjunga (28,156) and form a kind of horse-shoe, whence dependent spurs project southwards, gradually contracting and lessening in height until they reach the junction of the Rungit and the Tista. Thus the country is split up into a succession of deep valleys surmounted by open plateaux cut off from one another by high and steep ridges, and lies at a very considerable elevation, rising from 1000 feet above sea-level at its southern extremity to 16,000 or 18,000 feet on the

north. The main trade-passes into Tibet, such as the Jelep (14,500), Chola (14,550), and Kangra-lama (16,000), are not nearly so high as those met with in the western Himalaya, while those into Nepal are less than 12,000 feet.

Formerly the area of the state was much more extensive, but in the beginning of the 18th century Bhutan appropriated a large tract of country on the east, while the close of the century saw the Gurkha kingdom of Nepal absorb a much larger slice on the west; on the south the present British district of Darjiling was carved out of the residue at various times from 1835 to 1861. Tibet, moreover, appears to have resumed the Am-mochu valley towards the end of the 19th century.

Physical features. Small though the country is now a wide variation of climate makes it peculiarly interesting. From a naturalist's point of view it can be divided into three zones. The lowest, stretching from 1000 to 5000 feet above sea-level, may be called the tropical zone; thence to 13,000 feet, the upper limit of tree vegetation, the temperate; and above, to the line of perpetual snow, the alpine. Down to about 1880 Sikkim was covered with dense forests, only interrupted where village clearances had bared the slopes for the purposes of cultivation, but at the present time this description does not apply below 6000 feet, the upper limit at which Indian corn ripens; for here, owing to increase of population (particularly the immigration of Nepalese settlers), almost every suitable spot has been cleared for cultivation. The exuberance of its flora may be imagined when it is considered that the total flowering plants and ferns together comprise some 4000 species; there are more than 200 different kinds of ferns, 400 orchids, 20 bamboos, 30 rhododendrons, 30 to 40 primulas, and many other genera are equally profuse; in fact Sikkim contains types of every flora from the tropics to the poles, and probably no other country of equal or even larger extent can present such infinite variety. Butterflies abound and comprise about 600 species, while moths are estimated at 2000. Birds are profusely represented, numbering between 500 and 600 species. Mammals, however, are not numerous, only amounting to 85 different kinds. Reptiles, though existent in some variety, are not commonly met with, and fatal cases of snake-bite are almost unknown. Copper and lime are the chief minerals found and worked in Sikkim, but they are of little commercial value at present.

Government and population. The population is essentially agricultural, each family living in a house on its own land: there are no towns or villages, and the only collection of houses, outside the Lachen and Lachung valleys, are the few that have sprung up round country market-places, such as Rhenock, Dikkeling, and Gantok; but in the above-mentioned valleys the inhabitants, who are Bhutanese in origin and herdsmen in occupation, have large clusters of well-built houses at various altitudes up the valleys, which they occupy in rotation according to the season of the year.

The seat of government, or in other words the palace of the Raja, was, until the irruption of the Nepalese, situated at Rubdentze, in the western centre of the state; but when that place was taken and destroyed by the Ghurkhas, a new palace was built at Tumlong, close to the eastern and Tibetan boundary, while a subsidiary summer residence was erected on the other side of the Chola range at Chumbi, in the Am-mochu valley. At the present time the Raja and his court remain in the more open country at Gantok, where the British political officer and a small detachment of native troops are also stationed.

The earliest inhabitants of Sikkim were the Rong-pa (ravine folk), better known as the Lepchas, probably a tribe of Indo-Chinese origin; but when or how they migrated to Sikkim is unknown. The reigning family, however, is Tibetan, and claims descent from one of the Gyalpos or princelings of eastern Chinese Tibet; their ancestors in course of several generations found their way westwards to Lhasa and Sakya, and thence down the Am-mochu valley: finally, about the year 1604, Penchoo Namygé was born at Gantok, and in 1641, with the aid of Lha-tsan Lama and two other priests of the Duk-pa or Red-hat sect of Tibet, overcame the Lepcha chiefs, who had been warring among themselves, established a firm government and introduced Buddhist Lamaism as a state religion. His son, Tensung Namgyé, very largely extended his kingdom, but much of it was lost in the succeeding reign of Chak-dor Namgyé (1700–17), who is credited with having designed the alphabet now in use among the Lepchas.

History. Between 1776 and 1792 Sikkim was constantly at war with the victorious Ghurkhas, who were, however, driven out of part of their conquests by the Chinese in 1792; but it was not until 1816 that the bulk of what is known to us as Sikkim was restored by the British, after the defeat of the Nepalese by General Ochterlony.

The British resumed the whole of the plains (Terai) and the outer hills, as punishment for repeated insults and injuries caused by the rulers of Sikkim, who had become wholly pro-Tibetan in feeling and policy. Matters grew so bad that in 1886 the Raja Tho-tub Mamgyé refused to carry out his obligations under the treaty of 1861, and defiantly persisted in living in Tibet; his administration was neglected, his subjects oppressed, and a force of Tibetan soldiers was allowed, and even encouraged, to seize the road and to erect a fort within sight of Darjiling. After months of useless remonstrance, the Government was forced in 1888 to send an expedition, which drove the Tibetans back over the Jelep pass. A convention was then concluded with China in 1890 whereby the British protectorate over Sikkim was acknowledged and the boundary of the state defined; to this was added a supplemental agreement relating to trade and domestic matters, which was signed in 1893. Since that time the government has been a semi-independent one under the Maharaja, assisted by a council of seven or eight of his leading subjects, and guided by a resident British officer. Crime, of which there is little, is punished under local laws administered by local kazis or petty chiefs.

Statistics. No trustworthy census has ever been taken in Sikkim; prior to 1886 the population was put down at between 7000 and 10,000, but in 1891 a rough enumeration gave a population of 30,500; of this number 5800 were Lepchas, 5000 Bhuteas or Tibetans, 12,000 Limbus, Gurungs, Murmis, and other hillmen more or less allied to one another, and in religion Hindu tainted with Lamaism, while the balance was made up of pure Nepalese. The census of 1901 gave a population or 59,242.

The state religion is Buddhism as practised in Tibet, but is not confined to one particular sect; while among the heterogeneous population of Sikkim all manner of religious cults can be found. Education is at a low ebb, though the monasteries are supposed to maintain schools, and missionary enterprise has established others.

The revenue of Sikkim has under British guidance increased from Rs.20,000 a year to nearly Rs.3,50,000, derived chiefly from a land and poll tax, excise, and sale of timber; the chief expenditure is in the maintenance of the state, which practically means the Raja's family, as there are no soldiers and no police; and also in the improvement of communication. The country can now boast a very complete system of mountain roads, bridged and open to animal (but not cart) traffic. British trade with Central Tibet is carried over the Jelep route, on the south-eastern border of Sikkim, and in 1898 amounted to 21½ lakhs in exports and imports, but in 1901 it did not exceed 13 lakhs, though to this another 4½ lakhs must be added for the Bengal–Sikkim trade.

Rajas of Sikkim (Dejong-Gyalpo): Penchoo Namygé (1641–70), Tensung Namgyé (1670–1700), Chak-dor Namgyé (1700–17), Gyur-mé Namgyé (1717–34), Penchoo Namgyé (1734–80), Tenzing Namgyé (1780–90), Cho-phoe Namgyé (1790–1861), Sikhyong Namgyé (1861–74), Tho-tub Namgyé, 1861, the present Maharaja.

SILCHAR, a town of British India, in the Cachar district of Assam, of which it is the headquarters; situated in 24° 49′ N. and 92° 51′ E., on the left bank of the river Barak, with a railway station; 271 miles north of Chittagong. Population (1881), 6567; (1891), 7523; municipal income (1897–98), Rs.19,721; incidence of taxation, R.1.5.6; death-rate (1897), 65·53 per thousand. Silchar is the centre of an important tea industry. The military cantonment had 336 men in 1898. Silchar is the headquarters of the volunteer corps known as the Surma Valley Light Horse. The Government high school had 185 pupils in 1896–97, and there is a law class and an unaided school for girls. A branch railway (19 miles) from Badarpur, the terminus of the Assam–Bengal line, was opened in November 1898.

SILCHESTER, a parish of Hampshire, England, lying half-way between Reading and Basingstoke. It has become one of the most interesting sites for archæological excavation. Here, on a hill with a wide prospect east and south and west, is an open space of 100 acres, in shape an irregular hexagon, enclosed, in a circuit of a mile and a half, by the massive ruins of a city wall, still standing here and there some twenty feet high (Fig. 1). Outside, on the east, is the grassy hollow of a tiny amphitheatre; on the west a line of earthworks runs in wider circuit than the walls. The area within the walls is a vast expanse of cultivated land,

unbroken by any vestige of antiquity; yet the soil is thick with tile and potsherd, and in hot summers the unevenly growing corn reveals the remains of streets and houses close beneath the surface. This is the Romano-British town Calleva Atrebatum. Ptolemy and the Itinerary tell us its name; of its history nothing is known; its character has been disclosed for us by the spade.

Casual excavations were made here in 1744 and 1833; more systematic ones intermittently between 1864 and 1884 by the Rev. J. G. Joyce and others; finally, in May 1890, the complete uncovering of the whole site was commenced by Mr G. E. Fox and others, with the aid of the London Society of Antiquaries. The work was carried on with splendid perseverance, and in 1902 was three-quarters finished. The chief results concern the buildings of the town. Though these have vanished wholly from the surface, the foundations and lowest courses of their walls survive fairly perfect below ground: thus the plan of the town can be minutely recovered, and evidence accumulates on two points—the character of the buildings which made up a town like Calleva, and the character of Romano-British buildings generally. On the other hand, little that is new has been learnt either as to the history of the place or as to that wide topic, the smaller details of ancient life; for instance, the developments of Roman provincial pottery have received scanty illustration. This is partly because Silchester has yielded few small objects of note, partly because its remains do not usually lie in strata which can be dated, and partly because the excavators have concentrated themselves on plans of buildings. Of these buildings the chief are:—

(1) *Forum.*—Near the middle of the town was a rectangular block, covering two acres. It comprised a central open court, 132 feet by 140 feet in size, surrounded on three sides by a corridor or cloister, with rooms opening on to the cloister (Fig. 2). On the fourth side was a great hall, with rooms opening into it from behind. This hall was 270 feet long and 58 feet wide; two rows of Corinthian columns supported the roof, which may have stood 50 or 60 feet above the floor; the walls were frescoed or lined with marble, and for ornament there was probably a statue or two. Finally, a corridor ran round outside the whole block. This was the Forum where the local authorities had their offices, justice was administered, traders trafficked, citizens and idlers assembled. We cannot apportion the rooms to their precise uses, but the great hall was plainly the Basilica, for meetings and business; the rooms behind it were perhaps law courts, and some of the rooms on the other three sides may have been shops. Similar municipal buildings existed in most towns of the western Empire, whether they were full municipalities or (as probably Calleva was) of lower rank. The Callevan Forum seems in general simpler than others, but its Basilica is remarkably large. Probably the British climate compelled more indoor life than the sunnier south. Many Fora have been examined in other provinces; this is the only instance adequately excavated in Britain.

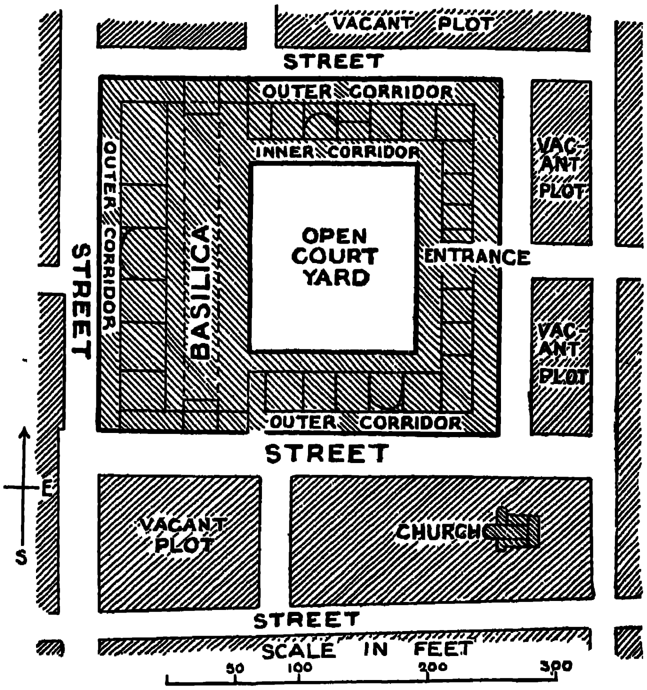

Fig. 2.—Plan of Forum, Basilica, and Surroundings.

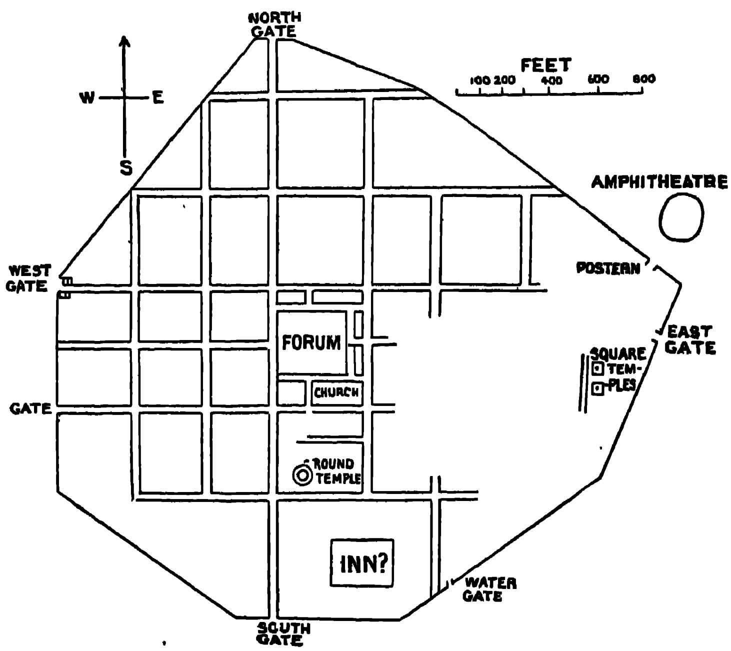

Fig. 1.—General Plan.

(2) *Temples.*—Two small square temples were in the east of the town; the cella of the larger measured 42 feet square, and was lined with Purbeck marble. A third, circular, temple stood between the Forum and the south gate.

(3) *Church.*—Close outside the south-east angle of the Forum was a small edifice, 42 feet long by 27 feet wide, consisting of a nave and two aisles, which ended at the east in a porch of the width of the building, and at the west in an apse and two flanking chambers (Fig. 3). The nave and porch were floored with plain red tesseræ: in the apse was a simple mosaic panel in red, black, and white. Round the building was a yard, and in it a well near the apse, and a small structure of tile with a pit near the east end. No direct indication of date or use was discovered. But the ground plan is that of an early Christian church of the "basilican" type. This type comprised nave and aisles, ending in an apse and two chambers resembling rudimentary transepts, and having at the other end a porch (*narthex*). Previous to A.D. 420 the porch was often at the east end and the apse at the west; the altar, often movable, stood in the apse—at Silchester perhaps on the mosaic panel. A court enclosed the whole; near the porch was a laver (*cantharus*) for the ablutions of intending worshippers.

Several such churches have been found abroad, especially in Roman Africa; no other satisfactory instance is known in Britain.

(4) *Private Houses.*—The private houses of Silchester are of two types. They consist either of a row of rooms,

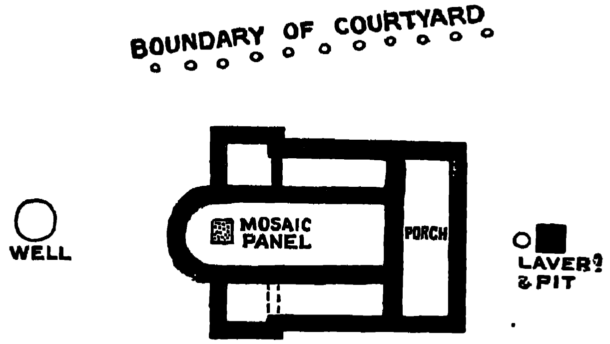

FIG. 3.—Plan of Christian Church.

with a corridor along them, and perhaps one or two additional rooms at the ends; or of three such corridors and rows of rooms, forming three sides of a large square yard. They are necessarily detached houses, standing each in its own garden. The country houses of Roman Britain have long been recognized as embodying these (or allied) types; now it becomes plain that they are the normal types throughout Britain. They differ widely from the town houses of Rome and Pompeii: they are less unlike some country houses of Italy and Roman Africa; but their real parallels occur in Gaul, and they may be Celtic types modified to Roman use, like Indian bungalows. Their internal fittings—hypocausts, frescoes, mosaics—are everywhere Roman; those at Silchester are average specimens

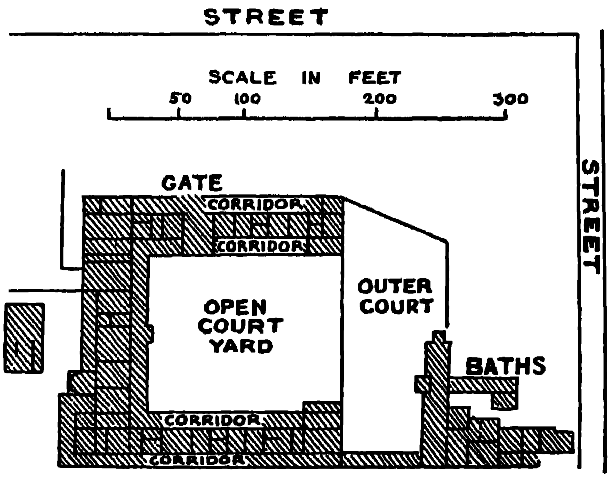

FIG. 4.—Plan of Supposed Inn and Baths.

and, except for one mosaic, not individually striking. The largest Silchester house, with a special annexe for baths, is usually taken to be a guest-house or hotel for travellers between London and the west (Fig. 4). Altogether, the town probably did not contain more than seventy or eighty houses of any size, and large spaces were hardly built over at all.

(5) *Industries.*—Shops are conjectured in the Forum and elsewhere, but were not numerous. Remains of dyers' furnaces, of a little silver refinery, and perhaps of a bakery have been noted.

(6) *Streets, &c.*—The streets were paved with gravel: they varied in width up to 28½ feet. They intersect regularly at right angles, dividing the town into square blocks, like Mannheim or Turin: plainly they were laid out all at once, possibly by Agricola (*Tac. Agr.* 21), possibly later. There are four principal gates: the eastern and western gates are not exactly opposite. The walls are constructed of flint, "bonded" with stone, and backed with earth; they have no external bastions or towers. In the plans (but not in the text) of the excavators' reports they are shown as erected subsequent to the streets.

No traces of theatre, meat-market, public baths, or aqueduct have been found; water was got from wells lined with wooden tubs, and must have been scanty in dry summers. Smaller objects—pottery, coins, window and bottle glass, bronze ornaments, iron tools, &c.—abound, but few pieces are individually notable. The most important feature is the absence of "Late Celtic" artistic traditions and the dominion of Roman fashions: with which we may join the fact, proved by inscriptions, that even the lower classes spoke Latin. The old tribal centre of the Atrebates had become a Romanized country town. Such, sometimes larger, more often smaller, were (we may think) the country towns which sheltered most of the town life in Roman Britain.

See *Archæologia*, xl., xlvi., lii., and following vols.; *Victoria History of Hampshire*, i. 271, 350. Reading Museum has a rich collection of objects, models, &c. (F. J. H.)

Silesia, Austrian (German, *Oesterriechisch-Schlesien*), a duchy and crownland of the cis-Leithan part of the Austro-Hungarian monarchy. Population in 1890, 605,649; in 1900, 680,529, equivalent to 342·5 per square mile. In some parts of this crownland, next to Lower Austria the most densely populated of the monarchy, there are 1000 inhabitants per square mile. The proportion of females to males in 1890 was 1096 to 1000; 48 per cent. German, 30 per cent. Poles, and 22 per cent. Czechs; 84·4 per cent. Roman Catholics, 13·91 per cent. Protestants, and 1·65 per cent. Jews. In 1897 the marriage-rate was 8·49, the birth-rate 39·9, or excluding still-births, 38·8, and the death-rate 27·16 per thousand. Of the births 10·6 per cent. were illegitimate.

Austrian Silesia sends 12 members to the Reichsrath, of whom 2 are returned by the new universal suffrage curia (9 German Opposition, 1 Pan-Germanic, 1 Social Democrat, and 1 Pole). The Diet is composed of 25 Germans, 3 Czechs, and 3 Poles.

There are 9 gymnasia and *real* gymnasia, a Protestant theological seminary, 15 technical agricultural and other schools, 10 intermediate and 505 public elementary schools (220 German, 116 Czech, 139 Polish, 30 mixed, &c.). In 1890 the proportion of illiterates was 8·7 per cent., a reduction of 3·1 per cent. in the preceding decade. Of the 49 periodicals published, 34 are German, 9 Polish, 5 Czech, and 1 Italian.

Since 1885 there has been a diminution of 7 per cent. in the proportion engaged in agricultural and forestry, now 41·25 per cent., and an increase of 15 per cent. in the proportion engaged in mining and industry (42·12 per cent.). This has been accompanied by comparatively little change in the nature either of the agricultural or industrial production. The mountainous parts are largely devoted to dairy-farming, the breeding of sheep, geese, and pigeons, hunting and fishing being also important resources. The coal-mines furnish some 5½ million tons annually, equivalent to 41½ per cent. of the entire Austrian product. With the exception of a small quantity of lignite, it is the only mineral produced. The staple textile, iron and steel industries flourish. There were in 1899, 357 miles of railway, 2303 miles of roads, and 17 miles of waterway. There were 183 post and 73 telegraph offices, with 761 miles of line and 2270 miles of wire.

The political life of the province turns upon the efforts of the Poles and Czechs to secure increased educational facilities in their own languages, in which they are encouraged by their compatriots in the adjoining provinces, and upon the occasional explosions of the chronic discontent of the mining and industrial population.

See PETER. *Das Herzogthum Schlesien.*—SLAMA. *Oesterreichisch Schlesien.* (Æ. O'N.)

Silesia, an eastern province of Prussia, with an area of 15,566 square miles, and population (1895), 4,415,309; (1900), 4,668,857; the largest province of the kingdom in area, and in respect of population the second (after the Rhine province). The density per square mile amounts to 300 persons. The south-eastern extremity of the province contains one of the principal coal-fields of the Prussian monarchy, and is the centre of the zinc-mining industry of Germany. In 1900 the mines yielded 29,596,750 tons (in 1881, 16,220 tons) of coal, valued at £11,420,500; 802,500 tons of lignite, valued at £150,750; 437,370 tons of iron-ore, valued at £142,400; 521,570 tons of zinc, valued at £774,350; 39,575 tons of lead, valued at £214,900; and 7280 tons of iron pyrites, valued at £3450. In 1900 the number of workmen employed in the coal-mines was 93,286, in the other mines about 15,600. The smelting furnaces yielded 742,820 tons of iron, valued at £2,493,450; 102,130 tons of zinc, valued at £1,984,400; 24,925 tons of lead, valued at £424,200; 286,250 oz. of silver, valued at £46,050; and 84,415 tons of sulphuric acid, valued at £116,400. The iron foundries, forges, &c., had an output of 681,900 tons of pig iron, iron bars, rails, &c., of the aggregate value of £5,177,550. In 1900 the live stock included 1,526,987 cattle, 951,577 pigs, 398,049 sheep, and 319,857 horses. In the same year 130 tons of tobacco were gathered off 250 acres of ground. In 1900 the sugar refineries and factories produced 238,650 tons of sugar; the breweries, 77,945,000 gallons of beer; and the distilleries, 10,985,950 gallons of pure alcohol. (For further particulars, see under PRUSSIA).

Silistria, an ancient fortified town, chief town of a department of Bulgaria, on a peninsula of low ground projecting into the Danube, 60 miles below Rustchuk. There are extensive vineyards in the neighbourhood, and tobacco is also cultivated. The town possesses flour-mills, cloth factories, and tanneries, and has a considerable trade in wine, corn, and wood. Population (1892), 11,718; (1900), 12,133.

Silver.—From the metallurgical point of view, silver ores may be classified as real silver ores and argentiferous ores. The former consist of silver minerals and gangue (vein matter, country-rock). The leading silver minerals are native silver, Ag; cerargyrite, AgCl; argentite, Ag_2S; proustite, $3Ag_2S+As_2S_3$; pyrargyrite, $3Ag_2S+Sb_2S_3$; dolybasite, $9Ag_2S+As_2S_3$; and stephanite, $5Ag_2S+Sb_2S_3$. The silver is commonly recovered by milling, *i.e.*, amalgamation or lixiviation. Argentiferous ores consist of silver-bearing base-metal minerals and gangue. Lead and copper ores, carrying silver in some form or other, are the leading representatives. The silver is extracted from the gangue with the base metal, usually by smelting, and the two are then separated by special processes (see LEAD; COPPER). Milling is cheaper than smelting, but the yield in silver is lower. Often it is more profitable to smelt real silver ores with argentiferous ores than to mill them, the greater cost being more than balanced by the increased yield. Milling is practised mainly in isolated localities near the mine producing the ore. As any given region is opened up by railways, cheapening transportation, milling is apt to give way to smelting. Thus on the American continent, which produces the bulk of the world's silver, milling is still prominent in South America and Mexico, while in the United States it has to a considerable extent been replaced by smelting.

Amalgamation is based on the property of quicksilver to extract the silver from finely-pulverized ore and collect it in the form of an amalgam. When the rock has been separated from the amalgam by a washing operation, the quicksilver is recovered by distillation in an iron retort, and the remaining crude retort-silver melted into bars and shipped to a refinery, which removes the impurities, the leading one of which is copper. A silver ore is either free-milling or refractory, that is, the silver mineral is readily amalgamated or it is not. In free-milling ore the silver is present either in the native state, or as chloride or as simple sulphide. Complex silver minerals (sulph-arsenides and antimonides) which are difficult to amalgamate must be made amenable to quicksilver, and the simplest way of doing this is to convert the silver into chloride. This is imperfectly accomplished, in the wet way, by cupric and cuprous chloride solutions, but completely so, in the dry way, by roasting with salt (chlorodizing roasting). According as a preliminary chlorodizing roast has or has not been given, the process is classed as roast-amalgamation or raw-amalgamation. The leading raw-amalgamation processes are the Patio and Washoe; then follow the Cazo, Fondon, and Kröhnke; of the roast-amalgamation processes, the European Barrel or Freiberg, the Reese River, and the Franck-Tina are the most important.

The *Patio* process (for an outline of which see *Ency. Brit.* vol. xxii. p. 70) is carried out principally in Mexico. It aims at amalgamating the silver in the open in a circular enclosure, the floor of which is generally built of flagstones. In order to facilitate the decomposition of the silver-mineral, salt and magistral are worked into the wet pulp spread out on the floor. Magistral is cupriferous pyrites roasted to convert the copper into soluble sulphate, which is the active agent. The amalgamation proceeds very slowly, as the sole extraneous heat is that of the sun. According to Laur, at Guanaxuato, Mexico, 92·77 per cent. of the total silver recovered was extracted after 12 days, 97·55 per cent. after 25 days, 99·70 per cent. after 28 days, and 100 per cent. after 33 days. The loss of quicksilver in the process is large, owing to the formation of calomel which is not saved. The yield in silver is low unless the ores are exceptionally free-milling; the bullion produced is high-grade, as refractory silver minerals are hardly attacked. The process is suited to easy ores and a region where the climate is warm and dry, and horse- or mule-power, labour, and quicksilver are cheaper than fuel and water.

The *Washoe* process is the leading raw-amalgamation process of the United States, where it was invented in 1859 by A. B. Paul. It consists in wet-stamping coarsely crushed ore, settling the sands and slimes produced, and grinding and amalgamating them in steam-heated iron pans with or without the use of chemicals (salt and blue vitriol). The ores may contain a larger proportion of sulphurets and complex silver minerals than with the Patio process and still give a satisfactory extraction. They are crushed to egg-size in a rock-breaker, and pulverized to pass a 40-mesh sieve in a California stamp-mill, which treats in 24 hours about 3 tons per stamp. A 10-stamp mill is fed by one rock-breaker, and discharges the liquid pulp into 10–15 wooden settling tanks, 9 by 5 by 8 feet, the settled contents of which are shovelled out and charged into the pans. The pan in general use is the combination pan. It has a flat cast-iron bottom, 5 feet in diameter, and wooden sides about 30 inches high, the lower parts of which are lined with cast iron. In the centre is a hollow cone, through which passes the driving shaft, geared from below. This turns the grinding apparatus (driver with muller), which can be raised and lowered. The speed is 60–90 revolutions per minute. To the bottom and muller are attached grinding plates (shoes and dies), which are replaced when worn; and to the sides three wings, to deflect the moving pulp towards the centre, and thus establish the necessary pulp current. The lower side of the bottom has also a steam-chest. A 10-stamp mill has 4–6 pans, which receive 2-ton charges. In working, the muller is raised half an inch, the pan charged with water and then with ore, the muller is lowered, salt and blue vitriol are added, and the charge ground for 3–4 hours. The pulp is heated with live steam to about 90° C., and kept at that temperature by exhaust steam in the bottom-chest. After grinding, the muller is raised and quicksilver added, and the silver then amalgamated in 3–4 hours. In amalgamating without the use of chemicals, finely divided iron, worn from the shoes and dies in the stamp-mill and the pan, decomposes cerargyrite and argentite, and the liberated silver is taken up by the quicksilver; the process is hastened by adding salt. When salt and blue vitriol are added to the charge, they form sodium sulphate and cupric chloride ($2NaCl+CuSO_4=Na_2SO_4+CuCl_2$), both of which are readily soluble in water. Cupric chloride acts upon argentite ($Ag_2S+CuCl_2=2AgCl+CuS$), proustite ($4Ag_3AsS_3+12CuCl_2=$

$8AgCl, 2Ag_2S, 2CuS, As_2S_3, 5S$), pyrargyrite ($2Ag_3SbS_3 + 4CuCl = 6AgCl + 2CuS + Sb_2S_3 + S$), and is also reduced to cuprous chloride by metallic iron ($2CuCl_2 + Fe = Cu_2Cl_2 + FeCl_2$). This salt, insoluble in water but soluble in brine, also acts upon argentite ($Ag_2S + Cu_2Cl_2 = 2AgCl + CuS + Cu$) and pyrargyrite ($2Ag_3SbS_3 + Cu_2Cl_2 = AgCl + Ag_2S + 2Ag + 2CuS + Sb_2S_3$), and would give with silver sulphide in the presence of quicksilver, the Patio-reaction: metallic silver, cupric sulphide, and mercurous chloride ($2Ag_2S + Cu_2Cl_2 + Hg = 4Ag + 2CuS + Hg_2Cl_2$), but the iron decomposes the quicksilver salt ($Hg_2Cl_2 + Fe = Hg_2 + FeCl_2$), setting free the quicksilver. The amalgamation is rapid. Thus Austin found that at the Charleston mills, Arizona, 92·13 per cent. of the total silver recovered was extracted after 1 hour, 94·10 per cent. after 2 hours, 95·92 per cent. after 3 hours, and 100 per cent. after 4 hours. The loss in quicksilver is small, as there is no chemical loss inherent in the process; the yield is relatively high, but the bullion is liable to be low-grade, on account of copper being precipitated and amalgamated. When the charge has been worked, the contents of the pan are discharged into a settler, in which the amalgam is separated from the sands. It has the same general construction as the pan. It is 8 feet in diameter and 3 feet deep. The bottom, slightly conical, has a groove near the circumference to catch the amalgam, which is withdrawn through a discharge-spout into a bowl. In the sides at different levels are three discharge-holes for water and sand. The muller reaches to within three inches of the bottom and makes 12–15 revolutions per minute. In settling, the pulp is diluted by a small stream of water, and the thinned pulp drawn off, first through the top discharge-hole and then through the other two, the bottom one being about 8 inches above the amalgam. Settling takes about half the time required to work a charge in the pan, hence one settler serves two pans. The amalgam is dipped out from the bowl into a canvas bag (the strainer), to separate the excess of the quicksilver from the pasty amalgam, which is then retorted and melted. The cost of treating a ton of ore in the western part of the United States is from \$3 to \$7. At some works treating ores containing sulphurets which do not yield their silver to quicksilver, concentration apparatus (see ORE-DRESSING) is inserted between the stamps and the settling tanks to remove the sulphurets, which are worked by themselves; at other works they are recovered from the sands after these have left the settlers. In order to do away with the handling of the wet pulp, and to obtain a higher extraction, M. P. Boss has modified the ordinary plant by making the pulp flowing from the stamps pass through a grinding pan, then through a series of amalgamating pans followed by a row of settlers.

A 20-stamp mill is served by 12 men in 24 hours. The Washoe process is independent of the climate, but it requires cheap power and an abundance of water.

In the *Cazo, Caldron*, or *Hot* process the pulverized silver ore is boiled in a copper-bottomed wooden vat, first with brine until the silver has been reduced by the copper, and then with quicksilver. The *Fondon* is an improvement on the Cazo. Bars of copper drawn over the bottom by mules or water-power (like the stone drags in the arrastra) grind off fine particles of copper, which hasten the reduction of the silver and diminish the formation of calomel. In the *Kröhnke* process the silver mineral of the pulverized ore is decomposed in a revolving barrel by a hot solution of cuprous chloride in brine in the presence of zinc or lead and quicksilver.

Chlorodizing Roasting. — In a chlorodizing roast chlorine produces its effect as nascent chlorine or gaseous hydrochloric acid. The leading reagents are salt (NaCl), sulphur trioxide (SO_3, produced in the roasting), and water vapour (H_2O). The decomposition of salt is expressed by $2NaCl + 2SO_3 = Na_2SO_4 + SO_2 + Cl_2$. In the presence of water-vapour the following reaction takes place: $2NaCl + SO_3 + H_2O = Na_2SO_4 + 2HCl$. As some water-vapour is always present, hydrochloric acid will invariably be formed with the chlorine. The roasting is carried on in hand and mechanical reverberatory furnaces, occasionally in muffle-furnaces. A chloridation of over 90 per cent. silver is the rule.

The *European Barrel or Freiberg* process (see *Ency. Brit.* vol. xxii. p. 70), perfected at Freiberg, Saxony, was abandoned there in 1856. In the United States it was used quite extensively in Colorado and Nevada, but has now been given up. The main reasons for this are the length of time required to finish a charge, on account of the absence of any extraneous source of heat, and the great care with which operations have to be carried out in order to obtain satisfactory results. The *Reese River* process consists in dry-stamping crushed dried ore and dried salt (separately or together), charging them into a roasting furnace, and amalgamating the chlorodized ore in an iron pan. The general arrangement and construction of a mill resemble those of the Washoe process. The apparatus for drying ore and salt varies greatly, drying-floors, dry-kilns, and continuous mechanical reverberatory furnaces with stationary and revolving hearths being used. The general construction of the pan is the same as in the Washoe process; the management, however, differs. The steam-chest is not used to such an extent, as the bottom would be prematurely corroded; less water is used, as the pulp would become too thin on account of the soluble salts (sodium chloride, sulphate, &c.) going into solution; and the roasted ore is not ground, as the hot brine readily dissolves the silver chloride from the porous ore, and thus brings it into intimate contact with iron and quicksilver. Chemical reagents are sometimes added—lime or sulphuric acid, to neutralize an excess of acid or alkali; bluestone, to form cuprous chloride with sodium chloride; and iron and zinc, to make the galvanic action more energetic and reduce the consumption of iron. The rest of the apparatus (settler, retort, crucible furnace) is the same as with the Washoe process. The Reese River process costs from half as much again to twice as much as the Washoe process.

The *Franck-Tina* process was developed in Bolivia for the treatment of refractory ores rich in zinc blende (ZnS) and tetrahedrite $4(Cu_2, Fe, Zn, Ag_2, Hg_2)S + (Sb, As, Bi)_2S_3$. The ore is given only a partial chlorodizing roast, on account of the great loss in silver that would be caused by the formation of zinc chloride ($ZnCl_2$). The large amount of soluble sulphates of iron and copper formed in the roast is made to act upon salt charged in a copper-bottomed amalgamating pan; the chlorides formed finish in the wet way the imperfect chloridation obtained in the furnace.

Lixiviation.—Ores suited for amalgamation can, as a rule, be successfully leached. In leaching, the silver ore is subjected to the action of solvents, which dissolve the silver; from the solution the silver is precipitated and converted into a marketable product.

The leading solvents are aqueous solutions of hyposulphite salts. Sodium chloride, characteristic of the Augustin process (see *Ency. Brit.* vol. xxii. p. 70), has almost wholly fallen into disuse; and potassium cyanide, which has become a very important solvent for finely divided gold, is rarely used in leaching silver ores. The use of sodium hyposulphite as solvent, and sodium sulphide as precipitant, was proposed in 1850 by Hauch and Percy, and put into practice in 1858 by Patera (*Patera* process); calcium hyposulphite with calcium polysulphide was first used by Kiss in 1860 (*Kiss* process, now obsolete); sodium hyposulphite with calcium polysulphide was adopted about 1880 by Hofmann (*Hofmann* process); finally, sodium hyposulphite with cuprous hyposulphite was first applied by Russell in 1884, who included in his process the acidulation of the first wash-water (to neutralize any harmful alkaline reaction), and the separation of lead with sodium carbonate from the silver solution previous to precipitating with sodium sulphide. In all processes the silver ore is finely crushed, usually by rolls, as, because making few fines, they leave the ore in the best condition for leaching. As a rule the ore is subjected to a preliminary chlorodizing roast, though occasionally it may be leached raw. The vats in common use are circular wooden tanks, 16–20 feet in diameter and 8–9 feet deep if the leached ore is to be removed by sluicing, 5 feet if by shovelling. They have a false bottom, with cloth or gravel filters. The basis of the following outline is the Patera process. The ore, supposed to have been salt-roasted, is charged loosely into the leaching vat and treated with water (to which sulphuric acid or blue vitriol may have been added), to remove soluble salts, which might later on be precipitated with the silver (base-metal chlorides), or overcharge the solution (sodium chloride and sulphate), or interfere with the solvent power (sodium sulphate). The vat is filled with water from above or below, in-and out-flow are then so regulated as to keep the ore covered with water. Any silver dissolved by the first wash-water is recovered by a separate treatment. After the wash-water has been drained off, the ore is ready for the silver solvent. This is a solution containing up to 2 per cent. of sodium hyposulphite ($Na_2S_2O_3 +$ 5 aq.), of which one part dissolves 0·485 parts silver chloride, = 0·365 parts metallic silver ($2AgCl + 3Na_2S_2O_3 = Ag_2S_2O_3, 2Na_2S_2O_3 + 2NaCl$). Silver arsenate and antimoniate are also readily soluble, metallic silver slightly so, silver sulphide not at all. (In the Russell process double salts: $4Na_2S_2O_3 \cdot 3Cu_2S_2O_3$, and $3Na_2S_2O_3$ $3Cu_2S_2O_3$ metallic silver and silver sulphide are readily soluble; thus it supplements that of Patera). After the silver has been dissolved by percolation, the last of the solvent still in contact with the ore is replaced by a second wash-water. The silver solution, collected in a circular precipitating vat (10 feet in diameter and 10 feet deep), is treated with sodium sulphide (or calcium polysulphide), unless sodium carbonate was first added to throw down any lead, present in the ore as sulphate, that had gone into solution. Silver sulphide falls out as a black mud, namely, $2Ag_2S_2O_3 + Na_2S_2 = Ag_2S + Na_4S_2O_6$ and $Na_4S_2O_6 + Na_2S_2 =$

$2Na_2S_2O_3 + 2S$ (or $Ag_2S_2O_3 + CaS_5 = Ag_2S + CaS_2O_3 + S_4$, and in part $CaS_2O_3 + Na_2SO_4 = CaSO_4 + Na_2S_2O_3$), with about 50 per cent. silver, and the solvent will be regenerated. If the sodium cuprous hyposulphite was used as a solvent in addition to the simple sodium hyposulphite, cuprous sulphide will be precipitated with the silver sulphide, and the precipitate will be of lower grade. At some works the silver is precipitated with sodium sulphide, and the liquor, after having been separated from the silver sulphide, is treated with calcium polysulphide, that by the precipitation of calcium sulphate the accumulation of sodium sulphate may be prevented. The precipitated silver (copper) sulphide is filtered, dried, and usually shipped to silver-lead works to be refined; sometimes it is converted into metallic silver at the works. The solution, freed from silver, is used again as solvent. Lixiviation has many advantages over amalgamation. It permits coarser crushing of the ore, the cost of plant is lower, the power required is nominal, the cost of chemicals is lower than that of quicksilver, less water is necessary, and the extraction is often higher, as silver arsenate and antimoniate are readily soluble, while they are not decomposed in amalgamation. On the other hand, silver and silver sulphide are readily amalgamated; and while they are not dissolved in the Patera process, they are in the Russell process.

Statistics.—The world's production of silver in 1900 was, according to *The Mineral Industry*, vol. ix. p. 315, in troy oz.: United States, 59,561,797; Canada, 4,446,505; Mexico, 55,804,420; Central America, 1,446,795; Argentina, 383,561; Bolivia, 10,432,685; Chile, 5,772,791; Colombia, 2,800,000; Ecuador, 81,000; Peru, 6,590,955; Austria, 1,272,022; Hungary, 675,750; France, 466,189; Germany, 6,243,326; Greece, 1,294,917; Italy, 1,081,707; Norway, 154,389; Russia, 163,960; Servia, 18,386; Spain, 5,909,418; Sweden, 73,626; Turkey, 65,363; United Kingdom, 191,927; Dutch East Indies, 1447; Japan, 1,810,375; Australasia, 14,063,244; other countries, 48,226; total, 180,854,781.

(H. O. H.)

Silves, a town of the district of Faro, Portugal, on the right bank of the Silves, 30 miles west-north-west from Faro. It is surrounded with walls and possesses a castle. Its manufactures include corks and soap. It produces corn, vegetables, and fruits, especially oranges, carob beans, and almonds (all three exported). Pigs are bred, and fishing is carried on in the river and at sea. Alfonso III. wrested Silves from the Moors. Population (1890), 8363; (1900), 9688.

Simbirsk, a government of East Russia, on the right bank of the Middle Volga, with an area of 19,110 square miles. Its geology has been carefully investigated, and it appears that all systems, beginning with the Carboniferous, are represented. The "Variegated Marls," which have been the subject of animated polemics among the Russian geologists, continue to remain problematic as to their exact age, but the thorough inquiries of Professor Pavloff have permitted the geological age of the Jurassic formations to be definitely settled. Triassic deposits appear in the north; Carboniferous and Cretaceous are spread in the eastern part of the province, where they are covered in many places by Tertiary deposits; Chalk and Eocene deposits chiefly crop up in the west, and the Chalk in the south. Post-Pliocene deposits containing bones of the mammoth and other extinct mammals cover the older formations. Sulphur, asphalt, salt, ochre, and iron-ore are extracted, as well as various building stones. The domiciled population, which was estimated at 1,655,500 in 1891, proved to be only 1,549,461 in 1897, when there were 799,660 women, and the urban population numbered 109,175. Nearly all the inhabitants either belong to the Russian Orthodox Church or are Nonconformists, there being only 144,440 Mussulmans. The government is divided into eight districts, the chief towns of which are Simbirsk (43,300), Alatyr (11,086), Ardatoff (4838), Buinsk (4216), Karsuñ (4613), Kurmysh (3484), Senghilei (5735), and Syzrañ (32,377). The number of schools in 1899 was 944, with 39,000 boys and 11,000 girls. School gardens and school farms have been widely introduced, and no fewer than 240 schools were provided with such facilities for practical instruction, while bee culture was taught in 55 schools, and various trades in 14 schools. Owing to the efforts of the *zemstvos* (local councils), sanitation is well looked after, and there are 32 hospitals and 91 infirmaries. Out of a total area of 7,502,500 acres of cultivated land in 1898, the peasant village communities held 4,495,800 acres, private owners 2,330,300 acres, the Imperial domains 602,500 acres, and the towns and the Crown 73,400 acres. In 1898 the forests covered 3,437,000 acres. The peasants are rapidly buying considerable quantities of land. Most of their allotments (more than 76 per cent.) are under fields, and besides what they own they rent 501,500 acres from the private owners. No fewer than 3,483,500 acres were under cereal crops in 1900, and the average yield in 1895–99 was: wheat, 884,000 cwt.; rye, 9,945,000 cwt.; oats, 4,402,000 cwt.; barley, 50,000 cwt.; all cereal crops, 17,436,000 cwt.; also potatoes, 3,311,000 cwt.

In 1898 there were 288,890 horses, 326,000 horned cattle, and 916,820 sheep. Good breeds of horses are kept, and a considerable export trade in them is carried on. Domestic trades give employment to nearly 15,300 persons; carts, sledges, wheels, and all sorts of wooden ware are made in the villages, as also are felt goods, boots, gloves, caps, handkerchiefs, ropes, and fishing-nets, all of which are widely exported. Large establishments, however, are not very numerous; factories, indeed, employ only 18,710 workers, and their aggregate annual returns do not amount to more than 10,640,000 roubles. They mainly comprise wool cloth mills (4,575,000 roubles), flour-mills (18 provided with rollers), and distilleries; there are also tanneries, glass, and starch works. The internal trade is chiefly carried on at 82 fairs, the chief of which are held at Simbirsk, Syzrañ, and Karsuñ. There is a considerable export trade in grain, mostly rye and flour. (P. A. K.)

Simbirsk, the capital of the above government, 576 miles by rail east-south-east of Moscow, between the Volga and the Sviaga, which here closely approach each other. It is one of the best built provincial towns of Russia. It has gymnasia for boys and girls, with a summer sanatorium for the pupils, numbers of other town and industrial schools for boys and girls alike, two public libraries, one of which has 44,000 volumes, three daily papers, a good theatre, and more than the usual number of philanthropic institutions. Its factories are of no importance, but its trade is considerable, especially that connected with its great fair in horses. In 1897 the population was 43,300.

Simla, a town and district of British India, in the Delhi division of the Punjab; the summer residence of the Viceroy and of the staff of the supreme Government. The town is 7075 feet above the sea; 58 miles by cart-road from the railway station of Kalka, which is 1116 miles from Calcutta. Population (1881), 12,258; (1891), 13,836; municipal income (1897–98), Rs.3,22,280; death-rate (1897), 23 per thousand. The sanitarium of Simla occupies a spur of the lower Himalaya, running east and west for about 6 miles. Three miles west is the cantonment of Jutogh. The minor sanitaria of Kasauli, Sabathu, Dagshai, and Solon lie some distance to the south. The hills all round are clothed with rhododendron and deodar. In 1897 the total rainfall was 51 inches, of which 38 inches fell from June to September; the maximum temperature was 82° F. in May, the minimum 32° in December; the prevailing winds are northerly.

Simla is gradually becoming the permanent headquarters of many of the official establishments. A vice-regal lodge, foreign office, secretariat buildings, army headquarters, public works office, and clerks' quarters have been built at imperial expense. The municipality has provided water and sewerage works and a fine town-hall, out of a loan of Rs.8,15,890. There are several hotels and banks. Simla is the headquarters of a volunteer rifle corps, 400 strong. Two breweries have a yearly out-turn of 39,000 gallons, with larger breweries at Kasauli and Solon. There are 11 printing-presses, issuing 5 newspapers and periodicals; and there are numerous libraries and institutes, of which the chief is the United Service Institution, with a subsidy of Rs.3,000 from Government. The Ripon hospital receives Rs.10,000 from endowment and Rs.1,500 from Government. Educational institutions include Bishop Cotton's school for boys, the Mayo industrial school for girls, several aided schools for European boys and girls, and two Anglo-vernacular schools for natives. The Lawrence military asylums are at Sonawar, near Kasauli.

The district of SIMLA has an area of 102 square miles. Population (1891), 44,642; (1901), 40,353; average density, 395 persons per square mile. The land revenue and rates in 1897–98 were Rs.21,151; cultivated area, 13,045 acres, of which 52 were under tea; number of police, 307; number of schools, 41, attended by 1864 boys, being 40 per cent. of the boys of school-going age; death-rate (1897), 22 per thousand. A railway on the metre gauge is under construction from Kalka to Simla, 68 miles, with several tunnels.

Simon, Sir John (1816– ——), English surgeon and sanitary reformer, was born in London 10th October 1816. His father, Louis Michael Simon, was for many years a leading member of the London Stock Exchange. Both his grandfathers were French emigrants, who carried on business in London and Bath respectively. His father died at the advanced age of almost ninety-eight, and his mother, after sixty-seven years of happy wedlock, when she had almost attained ninety-five years of age. Simon was educated at a preparatory school in Pentonville, spent seven years at Dr Burney's school in Greenwich, and then ten months with a German Pfarrer in Rhenish Prussia. His father intended him for surgery, and he began the study of medicine on 1st October 1833, when he was a few days short of seventeen. After the fashion of the time, he became an apprentice of Joseph Henry Green, the distinguished surgeon at St Thomas's, well known for his friendship for Samuel Taylor Coleridge, whose literary executor Green became. He qualified in due course, became a demonstrator of anatomy, and was assistant surgeon to King's College Hospital for several years; and in the autumn of 1847 he was appointed surgeon and lecturer on pathology at his old school, St Thomas's, where, with progressive changes, he continued to remain an officer. His life was divided between two great pursuits—the career of a surgeon, and the mastery and solution of many of the great problems of sanitary science and reform. In the spring of 1844 he gained the first Astley Cooper prize by a physiological essay on the thymus gland, and the following year was elected a fellow of the Royal Society. In 1847 he gave his first lecture at St Thomas's Hospital, on the "Aims and Philosophic Method of Pathological Research"; followed a little later by lectures on general pathology in relation to the principles of diagnosis, and the treatment of disease. These lectures were of great importance at the time, and of the utmost value in directing energy into new and profitable channels of work. Simon published many clinical surgical lectures of the greatest importance, and contributed a masterly article on "Inflammation" to Holmes's *System of Surgery*, which has become a classic of its kind. It was, however, on his appointment in 1848 as medical officer of health to the City of London, and afterwards to the Government, that Simon's great abilities found scope for congenial exercise. His first report to the City Commissioners was characterized by *The Times* of 8th November 1849 as of extraordinary interest, and the ablest, most lucid, and most temperate statement of modern sanitary condition and wants. His work in sanitary science has stimulated and guided its development, until it has reached in England the highest degree of excellence, and affords an example to the civilized world. He himself defined it as "proposing the physical, social, and, indirectly, the moral improvement of what is an immense majority of our fellow creatures. It transcends the importance of all other sciences, and seems in its beneficent operations most nearly to embody the spirit, and to fulfil the intentions, of practical Christianity." It is impossible to overestimate the value of Sir John Simon's work, or the importance of his influence in the furtherance of the public health, and the prevention of disease, and in inculcating right methods of medical government. In 1878, after filling other offices in the Royal College of Surgeons, he became its president, and in 1887 was created K.C.B. It was largely due to his advocacy that the new St Thomas's Hospital was rebuilt on its present site after it was compelled to leave its old habitation near London Bridge. As a surgeon, Simon's work came second to his interest in sanitary science, but he claimed priority over Cock in the operation of perineal puncture of the urethra in cases of retention from stricture. (W. MACC.)

Simon, Jules François (1814–1896), French statesman and philosopher, was born at Lorient in December 1814. His parents were of Jewish extraction, and the family name was Suisse, which he dropped, making a surname out of the prenomen Simon. He became a schoolmaster, and after holding various appointments at public schools in the provinces, was called to Paris by Victor Cousin, then omnipotent in all educationl matters, to lecture on the history of philosophy at the École Normale. In 1839 he became professor of philosophy at the Sorbonne; in the following year he published his *Études sur la Théodicée de Platon et d'Aristote*; and in 1844–45 his history of the philosophical school of Alexandria. These works, as well as the brilliancy of his lectures, gave him a high reputation, and after the revolution of 1848 he was elected to the National Assembly, which he quitted in the following year to serve on the Council of State, from which he was soon removed as too much of a Republican. His Republicanism was in fact most moderate, but thoroughly sincere, as he proved by refusing to take the oath of allegiance to Louis Napoleon's Government after the *coup d'état* of December 1851. Deprived of his professorship, he set, together with his wife, a splendid example of honourable poverty, living with the utmost frugality, and occupying himself with the production of a series of valuable treatises, written for general readers in a popular style, on religion, morals, and politics in their most practical aspects. *Le Devoir* appeared in 1854, *La Religion Naturelle* in 1856, *La Liberté de Conscience* in 1857, *La Liberté Politique* and *La Liberté Civile* in 1859, *L'Ouvrière* in 1861. In 1863 M. Simon was again elected to the legislature, and until 1869 worked with the group of five, headed by M. Émile Ollivier, who constituted the Republican parliamentary Opposition. He has given in his memoirs an entertaining account of this diminutive but by no means insignificant party. After the downfall of the Empire, M. Simon was made minister of public instruction by the Provisional Government, and after the

capitulation of Paris he became minister of the interior *ad interim*, and was sent to Bordeaux to put down the apprehended resistance of Gambetta to the peace concluded with Germany and the elections ordered by the Government. He successfully acquitted himself of this difficult task, and although defeated at Paris, was elected for the Marne. Upon the definitive reconstitution of the Ministry he resumed the portfolio of public instruction, and retained it until Thiers's fall in May 1873. Throughout his tenure of office his course was most conciliatory, especially towards the clergy, whose distrust of him he succeeded in greatly mitigating. In pursuance of this policy he directed the repair of the chapel founded as an expiation for the death of Louis XVI. on the one hand, and the restoration of Napoleon's statue in the Place Vendôme on the other. His ministry was also memorable for the organization of the French School of Archæology at Athens. In 1875 he was elected a member of the Academy and a life senator; and in December 1876, upon the resignation of M. Dufaure, was summoned by Marshal MacMahon to form a Cabinet, in which he was premier and minister of the interior. Here, as previously, his policy was one of conciliation, and he and the President would probably have worked together in harmony could they have been left to themselves. The constant pressure of the more advanced Republicans, however, alarmed the Conservative President, who on his part was worked upon by the anti-Republican conspirators about him, until, on 16th May 1877, he addressed M. Simon a letter which, although not openly demanding his resignation, left him no alternative but to tender it, unless he was prepared to resist and appeal to the Chambers. It was a very general opinion that he ought to have done so; and although he has vindicated himself by alleging his fear of provoking the Marshal to a *coup d'état*, it is certain that the transference of the Government of the Republic to its enemies might well have been its ruin but for their timidity and the extraordinary exertions of Gambetta. M. Simon never again held office, but frequently took an active part in the debates of the Senate, and proved himself one of the first orators of his time in the resistance which his conciliatory temper led him to offer to the sweeping educational reforms of M. Jules Ferry, and in his advocacy of free trade in 1891. On both occasions, however, he failed to convince his audience. He wrote in 1878 the history of M. Thiers's Government, and in 1887 published a most vivid personal sketch of Victor Cousin, the author of his fortune, but from whose despotism he had had much to endure. In his latter years he wrote two volumes of autobiographical memoirs, *Premiers Mémoires*, and *Le Soir de ma Journée*. They have many gaps, but contain much interesting matter. He died in Paris, 8th June 1896. No man prominently connected with French politics in the 19th century has left a higher reputation for moderation and patriotic disinterestedness; it is impossible to find a fault with his public conduct, unless his failure to resist Marshal MacMahon be accounted one. As a moral philosopher he ranks high, and his treatises have enjoyed a very wide circulation; in speculative philosophy he is less distinguished as a thinker than as a historian. (R. G.)

Simon's Town, a town and naval station in Cape Colony on Simon's Bay, an inlet on the west side of False Bay, 20 miles south of Cape Town, with which it is connected by rail. It occupies one of the finest sites in South Africa under the sickle-shaped headland, at the southern extremity of which stands the lighthouse of the Cape of Good Hope. The Imperial Parliament voted a sum of £2,500,000 for enlarging and strengthening the fortifications, docks, arsenal, and approaches of this station; and, in course of time, Simon's Town will be the strongest and most convenient naval station in the southern hemisphere. False Bay, which corresponds on the south to Table Bay on the north side of Table Mountain, is a spacious inlet which has an average depth of from 15 to 20 fathoms, and is completely sheltered on all sides except towards the south. Here a whole fleet of the largest vessels can ride safely at anchor under the formidable batteries by which it is proposed to guard the southern entrance between the Cape headland and Cape Hangklip, facing it on the opposite (east) side. The Cape headland forms the divide between the cold Antarctic current which passes to the west and the warm Mozambique current which sweeps round from the Indian Ocean and penetrates into False Bay, thus raising the temperature of Simon's Town 4° or 5° F. above that of Cape Town. Population (1887), 3000; (1900), 5000.

Simson, Martin Eduard von (1810–1899), German jurist and politician, was born at Königsberg, in Prussia, on 10th November 1810, of Jewish parentage. After the usual course at the gymnasium of his native town, he entered its university in 1826 as a student of jurisprudence, and devoted himself specially to the study of Roman law. He continued his studies at Berlin and Bonn, and, having graduated *doctor juris*, attended lectures at the École de Droit in Paris. Returning to Königsberg in 1831 he established himself as a *privat-docent* in Roman law, becoming two years later extraordinary, and in 1836 ordinary, professor in that faculty at the university. Like many other distinguished German jurists, *pari passu* with his professorial activity, Simson followed the judicial branch of the legal profession, and, passing rapidly through the subordinate stages of auscultator and assessor, became adviser (Rath) to the Landgericht in 1846. In this year he stood for the representation of Königsberg in the National Assembly at Frankfort-on-Main, and on his election was immediately appointed secretary, and in the course of the same year became successively its vice-president and president. The office to which he was called required in those days of storm and stress an unusual amount of nerve, tact, and calm judgment, and these qualities the young lawyer displayed to a remarkable degree. He controlled the sittings of the assembly during the revolutionary period with a dignity that would have done honour to a Speaker of ripe experience in any house of legislature in the world. In his capacity of president he appeared, on 3rd April 1849, in Berlin at the head of a deputation of the Frankfort Parliament to announce to King Frederick William IV. his election as German Emperor by the representatives of the people. The king, either apprehensive of a rupture with Austria on this account, or fearing detriment to the prerogatives of the Prussian crown should he accept this dignity at the hands of a democracy which he had alternately flouted and cajoled, refused the offer. Simson, bitterly disappointed at the outcome of his mission, resigned his seat in the Frankfort Parliament, but in the summer of the same year accepted a mandate as deputy for Königsberg in the popular chamber of the Prussian Landtag. Here he had at length an opportunity of displaying his skill in debate, and soon made his mark as one of the best orators in that assembly. A member of the shortlived Erfurt Parliament of 1850, he was again summoned to the presidential chair, and it was while acting in that capacity that he administered to Bismarck a well-merited rebuke. Bismarck, sitting as an ordinary deputy and being called to order by the president, made a loud aside to a colleague to the effect that they, being of noble birth, knew far better than the president

what licence to permit themselves. To this Simson replied, "What? You dare say that to me, a descendant in the direct line from Aaron!" Bismarck, to his honour be it said, immediately rose and bowed profuse apologies to his rebuker.

On the dissolution of the Erfurt assembly, Simson retired from politics, and for the next few years devoted himself exclusively to his academical and judicial duties. It was not until 1859 that he re-entered public life, when he was elected deputy for Königsberg in the lower chamber of the Prussian Landtag, of which he was president in 1860 and 1861. In the first of these years he attained high judicial office as president of the court of appeal at Frankfort on the Oder. In 1867, having been elected a member of the constituent assembly of the North German Federation, he again occupied the presidential chair, as he did also in the first regular Diet and the Zoll-parliament which succeeded it. On 3rd October of that year he presented on behalf of this body an address to King William I. of Prussia in the castle of Hohenzollern, the ancestral home of that royal house. On 18th December 1870 Simson arrived at the head of a deputation in the German headquarters at Versailles to offer the imperial crown to the King of Prussia in the name of the newly-elected Reichstag. The conditions under which Prussia might justly aspire to the hegemony in Germany at last appeared to have been accomplished. German unity had been cemented on the field of battle, and no obstacles, as in 1849, were in the way of the acceptance of the crown by the leading sovereign of the confederation. Thus the mission of the tribune of the people, who had the unique experience of twice offering a crown, was successful, and on 18th January 1871 King William of Prussia was proclaimed with all pomp German Emperor in the Salle des Glaces at Versailles. Simson continued as president of the Reichstag until 1874, when he retired from the chair, and in 1877 resigned his seat in the Diet, but at Bismarck's urging, "You owe it to your children, they will be proud of you," accepted, though reluctantly, the presidency of the supreme court of justice (Reichsgericht), and this high office he filled with great distinction until his final retirement from public life in 1891. In 1888 the Emperor Frederick bestowed upon Simson the order of the Black Eagle, which confers a patent of hereditary nobility, but it is characteristic of the modesty of this man that he never cared to adopt the title, but continued to sign himself simply "Dr Eduard Simson."

His political career coincides with the era of German struggles towards unity. As a politician he was one of the leaders of modern Liberalism, and though always loyal when appeals were made to patriotism, such as Government demands for the army, he remained obdurate on constitutional questions and refused to sacrifice a jot or tittle of popular rights; and he resolutely opposed the reactionary policy of the Prussian Conservatives. As president of the popular assembly, he conducted the proceedings with dignity and good feeling. He was a profound lawyer, but owing to the composition of the chambers in the supreme court not much scope was afforded for the display of individual talent. On his retirement from the presidency of the Reichsgericht, he left Leipzig and made his home in Berlin, where he died on 2nd May 1899. His Life has been published by his son, Bernard von Simson, under the title *Eduard von Simson, Erinnerungen aus seinem Leben*, 1900. (P. A. A.)

Sinaïa, a small town in Rumania, picturesquely situated in the Transylvanian Alps at about 15 miles from the Austro-Hungarian frontier at Predeal. It has become the fashionable summer resort of Bucharest society since the construction of the royal residence of Peles, "Castle Peles," called after the little mountain on which it is built. The building is of a mixed style of architecture, principally Old German, and the interior is fitted with magnificent wood carvings, and stained-glass windows illustrating the principal scenes of Carmen Sylva's writings. The town is lighted throughout by electricity. Population (1900), 2210.

The monastery of Sinaia, founded by Michel Cantacuzene in 1695, was the residence of the royal family until the present château was built. It consists of two courts surrounded by low buildings, the residence of the monks. In the centre of each court is a small church built in the Byzantine style, which has been renovated. The monks possess a library, in which are kept the valuable jewels, belonging to the Cantacuzene family.

Sinaloa, a state of Mexico, bounded on the N. by Sonora and Chihuahua, on the E. by Chihuahua and Durango, on the S. by the territory of Tepic and the Pacific, on the W. by the Gulf of California. Area, 33,681 square miles. Population (1879), 186,491; (1895), 258,865. It is the best watered state of the republic. The western hot belt or maritime zone is devoted to agriculture, the eastern or cold belt to mining. The yield of cereals, cotton, tobacco, sugar-cane, coffee, and fruits is valued at about $8,000,000 a year. It is claimed that Sinaloa is the richest mining region in Mexico, gold, silver, copper, iron, lead, being the principal products; there are also salt deposits, mineral springs, &c. An active trade is carried on through the port of Mazatlan, valued at about $18,000,000 a year. The state is divided into ten districts. The capital, Culiacan Rosales, with 10,487 inhabitants, is an important commercial centre, and has fine public buildings, manufactures, and a mint, and is connected with the port of Altata by rail. The principal towns are Mazatlan (15,852 inhab.), Mocorito (9971), Sinaloa, El Fuerte, Rosario, and San Ignacio.

Sind, or SCINDE, an historic region of India, now forming a division of the Bombay presidency. It comprises the four British districts of Karachi, Haidarabad, Shikarpur, Thar and Parkar, and Upper Sind Frontier, together with the native state of Khairpur. Total area, 53,898 square miles. Population (1891), 3,003,711; (1901), 3,412,373. The administrative headquarters are at Karachi, the seaport for all the Indus valley.

Excluding the native state of Khairpur, the area of British territory is 47,789 square miles. Population (1881), 2,413,823; (1891), 2,871,774, showing an increase of 19 per cent., due to the extension of cultivation by means of canals; average density, 60 persons per square mile, ranging from 100 in the irrigated districts of Haidarabad and Shikarpur to only 23 in the desert tract of Thar and Parkar. Classified according to religion, in 1891 Mahommedans numbered 2,215,147; Hindus, 567,536; Christians, 7764, of whom more than half were Europeans; "others," 81,327. The great majority of the inhabitants are undoubtedly of Hindu descent, converted to Islam a thousand years ago. They speak a language of their own, which is of special interest as being more nearly akin to the ancient Prakrit than any other of the modern tongues. In 1901 the population was 3,212,808, showing a further increase of 12 per cent.

Agriculture is almost entirely dependent upon irrigation from the Indus, the average annual rainfall not exceeding 8 inches. In 1897–98, out of a total cultivated area of 3,802,482 acres, no fewer than 2,917,624 acres, or 77 per cent., were irrigated, mainly from Government canals. The principal crops are millet, rice, wheat, oil-seeds, pulse, and cotton. In 1897–98 the receipts from 8 "major" irrigation works (of which only 4 were in operation) amounted to Rs.13,24,256, and the working expenses to Rs.3,81,653, showing a profit of Rs.9,42,603, or 6·65 per cent. on a capital expenditure of Rs.1,41,83,196. In addition, on 7 "minor" works there was a profit of Rs.10,14,301, or 28·6 per cent. on a capital expenditure of Rs.38,67,927. The revenue and rates in 1897–98 was Rs.1,10,25,351; number of police,

4195; pupils at school, 58,980, being 2·4 per cent. of the population, the same proportion as for the whole of Bombay.

Sind is traversed by the North-Western Railway, which follows the Indus from the Punjab to the sea at Karachi. The Indus is twice bridged: at Rohri, where the main line crosses the river, and a branch goes off to Quetta; and at Kotri, opposite Haidarabad, whence a line was opened into Rajputana in 1900. The sea-borne trade of Sind is concentrated at the port of Karachi, which ranks as the fifth port in India, with an aggregate of imports and exports (foreign and coasting) valued at about 15 crores of rupees (say ten millions sterling) a year. A little trade is carried on at the two petty ports of Sirgonda and Keti Bander. Navigation on the Indus by native boats is kept open by the Indus conservancy department. In 1897–98 the river-borne traffic between Sind and the Punjab amounted to 1,055,297 maunds, compared with 1,437,321 maunds in the preceding year. The external land trade of Sind with Afghanistan and Baluchistan was valued at Rs.52,18,329 for imports and Rs.29,06,489 for exports. The trade with Kandahar is declining, but that with Kalat and Las Beyla is increasing.

See A. W. Hughes. *Gazetteer of the Province of Sind.* London, 1876. (J. S. CO.)

Sindhia (Ali Jah Jaiaji Rao), Maharaja (1835–1886). The strength of loyal purpose which enabled Maharaja Ali Jah Jaiaji Rao to remain steadfast to his allegiance to the British Crown and faithful to his engagements, entitles him to a conspicuous place in the history of the 19th century. The full measure of credit which the Maharaja deserved for his behaviour in 1858 can only be appreciated by considering the past traditions of his family, the conditions of misrule which preceded his succession, and the circumstances of his own accession to ruling powers. The important state of Gwalior, now filling an area of 29,067 square miles in the centre of India, was at the commencement of the 18th century not only the first Maratha state, but a competitor for imperial rule. At the battle of Panipat, 1761, a Sindhia measured himself against Ahmad Shah Durani. The Emperor Shah Alam was restored by the Marathas to Delhi, and from 1788 was practically a prisoner in Sindhia's charge. Mahadaji Sindhia's influence reached to Mysore, for it was through his influence, in 1793, that the proposal of Lord Cornwallis to unite the Peshwa and the Nizam against Tipu was defeated. Daulat Rao Sindhia succeeded Mahadaji in 1794, and aided by French officers, he trained and collected a formidable army. His predecessor had in 1782 guaranteed the British treaty with the Marathas concluded at Salbai. But the growing power of Daulat Rao induced him to join with Berar in supporting Baji Rao against the British. Daulat Rao Sindhia secured Ahmednagar, seized most of Indore, and at the head of the strongest native army in India aspired to imperial rule. But the British victories of Assaye, Laswari, and Delhi broke his power, and before the outbreak of the Pindari war, Gwalior was reduced to the position of a protected principality. When Daulat Rao died in 1827, a distant relative succeeded, under the name of Jankoji Rao. The Regent, Baiza Bai, widow of the last Maharaja, quarrelled with the young chief, and the army took sides in the palace disputes which followed. Disorder prevailed without, and intrigues within the capital. The army was without pay or discipline, and turbulent classes, intolerant of British justice, sought an asylum in Gwalior, relying upon its past traditions to give them an opportunity for pursuing their lawless occupations.

The weak Jankoji died in 1843, and a lad of eight years named Bhagirat Rao, a very distant relative, was adopted by the child-widow of the late Maharaja. He took the name of Ali Jah Jaiaji Rao, and Mama Saheb was appointed Regent. The Regent was ousted by Dada Khasgiwalla, who, being hostile to the British, won the support of the army. War was imminent in the Punjab, and these proceedings at Gwalior could not be ignored. The surrender of Dada Khasgiwalla was obtained, and Lord Ellenborough demanded an interview with the young Maharaja on 16th December 1843. Sindhia's troops prevented the meeting, and on 29th December they attacked Sir Hugh Gough at Maharajpur, losing 56 guns and sustaining a decisive defeat. The victory of Panniar was won on the same day, and the army of Sindhia was scattered. By a treaty dated 13th January 1844 lands were ceded for the maintenance of a contingent force, the army was reduced, and the affairs of Gwalior were settled. But beneath the surface the embers of further disorder smouldered, until the outbreak of the Mutiny in 1857 again revived the hopes of Maratha supremacy. The Contingent mutinied in June, and the British agent withdrew. Every effort was made to induce the Maharaja to place himself at the head of a national movement. But Sindhia and his minister Dinkar Rao resisted all overtures. They resorted to presents and various expedients for keeping the troops of the state quiet, while Delhi was being recaptured and Cawnpore avenged. At last Tantia Topi appeared near Gwalior, and the Maharaja marched out to give him battle. His troops, however, went over to the mutineers and seized the fortress, and Sindhia, with his minister, escaped to Agra. On 19th June 1858 Sir Hugh Rose retook Gwalior and restored the Maharaja to his capital. Sindhia's name and influence would have been of incalculable value to the mutineers. His loyal conduct therefore received the grateful acknowledgment of the Government. The decorations of G.C.B., G.C.S.I., and C.I.E., the rank of an honorary general in the British Army, considerable grants of territory, and in 1886 the restoration of the fort of Gwalior, expressed the gratitude of the British for his services. Jhansi was received from Gwalior, and various territorial exchanges were effected. In the matter of railways, salt, and postal arrangements, the Maharaja readily co-operated with the Government of India. He died on 20th June 1886, leaving large accumulations of treasure, and was succeeded by his son Madho Rao. (W. L.-W.)

Singapore, an island and town situated at the southernmost extremity of the Malayan Peninsula in 1° 20′ N. and 103° 50′ E. The island is the most important portion of the Crown Colony of the Straits Settlements, and the town, which is the administrative centre of the colony, is the principal emporium of the trade of Southern Asia. Singapore is one of the most valuable of the minor possessions of Great Britain. It is very strongly fortified by guns and works of a modern type, upon which large sums have been expended by the Imperial Government, aided by a heavy military contribution from the colony. Its geographical position gives it strategic value as a naval base, whence the routes to and from the Far East can be commanded. It possesses a good harbour, docks, extensive coaling wharves, an admiralty dockyard, and considerable facilities for shipping. As a commercial centre it is unrivalled in that part of the world. The total value of the imports in 1898 was £16,416,831, and the exports in the same year valued £13,583,146. The ships using the port during 1898 numbered 10,013, with an aggregate tonnage of 9,086,556, of which 5768 were British, with an aggregate tonnage of 5,402,032. The revenue of Singapore for 1898 amounted to $2,963,550, exclusive of $46,150 received for land sales, and the expenditure was $2,427,061. On the island of Pulau Brani stand the largest tin-smelting works in the world, which annually pass through their furnaces more than half the tin produced. Singapore has also establishments for tinning pine-apples and a large biscuit factory. The city possesses few fine buildings,

but Government House, the new law courts, the gaol, the lunatic asylum, and the Hong Kong and Shanghai Bank are exceptions, as also is the cathedral of St Andrew's. There are three Roman Catholic churches, a Free church, an American mission, and several chapels belonging to other Nonconformist sects. There is a good racecourse and polo-ground, fine cricket and football fields, two golf links, and innumerable lawn-tennis courts. There is a town and a country club, as well as a German club, and both the latter have good bowling-alleys attached. Singapore is governed by its own municipality, under the supervision of the Colonial Government.

The atmospheric pressure registered in Singapore for 1898 showed 30·017 inches to be the highest on 28th January, and 29·711 inches to be the lowest on 9th November; the range for the year was 0·104 inches, and the mean for the year 29·870 inches. The temperature of Singapore registered 91·9° F. in the shade on 18th March 1898, that being the highest for the year. The lowest was 70·2° F., registered on 29th January. The range for the year was 12·7° F., and the mean was 79·7°. Temperature of solar radiation for 1898 was: highest 163·2° F. on 24th March; lowest 81·0° F. on 12th February; mean for 1898, 142·3° F. The temperature of nocturnal radiation on grass was: highest 75·1° F. on 30th June; lowest 66·9° F. on 24th March; mean of 1898, 71·2° F. Relative humidity: highest 98 per cent. on 7th September; lowest 53 per cent. on 10th November; mean for 1898, 81 per cent. Northerly and north-east winds prevail from the middle of October to the end of April, southerly and south-westerly winds from the beginning of May to the middle of October. The mean velocity of winds for the year 1898 was 177 miles, the greatest velocity recorded in 24 hours was 351 miles on 15th October. Rainfall: mean for 1898, 106·19 inches; maximum, 158·68 inches; maximum monthly fall, 23·94 inches in October; minimum monthly fall, 2·96 inches; greatest fall in 24 hours, 4·12 inches on 14th October.

The following shows the composition of the population, which numbered in all 228,555 in 1901: Europeans 3824, Eurasians 4120, Chinese 164,041, Malays 36,080, Indians 17,823, other nationalities 2667. The births registered in Singapore during 1898 numbered 3751, namely, 1960 males and 1791 females, being a ratio of 16·55 per mille. The deaths registered during the same period numbered 7602, namely, 5894 males and 1708 females, a ratio of 33·54 per mille. The excess of deaths over births is due to the fact that there are comparatively few women among the Chinese; the steady increase of the population in the face of this fact is to be attributed entirely to immigration, mainly from China, but to a minor extent from India also. The persons classed above under "other nationalities" are representatives of almost every Asiatic nation of importance, and of many African races, Singapore being one of the most cosmopolitan cities in the world. (H. CL.)

Singhbhum, a district of British India, in the Chota Nagpur division of Bengal. The administrative headquarters are at Chaibassa.

Area, 3375 square miles. Population (1881), 453,775; (1891), 545,488, showing an increase of 20 per cent., which must be partly due to more accurate enumeration; average density, 145 persons per square mile. Classified according to religion, in 1891 Hindus numbered 230,999; Mahommedans, 3215; Christians, 4864, of whom 129 were Europeans; aborigines, 306,410. In 1901 the population was 608,826, showing an increase of 12 per cent. The land revenue and rates in 1897–98 were Rs.1,47,907; number of police, 184; boys at school (1896–97), 12,842, being 31·5 per cent. of the male population of school-going age; registered death-rate (1897), 23·9 per thousand. The isolation of Singhbhum has been broken by the opening of the Bengal-Nagpur Railway, which has protected it from the danger of famine, and at the same time given a value to its jungle products. In 1896-97 no less than 538,767 cubic feet of sleepers were exported for a railway beyond Benares; and the net receipts of the forest department in that year were Rs.2,40,000, or twice the land revenue. There are three missions in the district—S.P.G., Lutheran, and Roman Catholic—which have been very successful among the aboriginal tribes, especially in the spread of education.

Singora, or SUNGKLA, the Sangore of early navigators, the most important port on the east coast of the Malay Peninsula, situated in 7° 12′ N. and 100° 35′ E. It was settled at the beginning of the 19th century by Chinese from Amoy, who placed themselves under the protection of the kings of Siam. Chinese influence is evident in the architecture of the walls of the town, as well as in many of the houses, and practically the whole of the commerce is in Chinese hands. The population numbers about 10,000, the greater part consisting of Siamese, and of Malays who reside in a settlement on the north side of the harbour, and have mostly adopted the Siamese language. The channel to the inland sea or great lake of Patalung, which makes the harbour one of the most picturesque in the Far East, affords a safe and commodious anchorage, but is rendered difficult of access by a dangerous bar. A good road across the peninsula connects the port with Keddah on the west coast. A concession was granted for a railway along this route, but no work has been done upon it. The chief products of the province are paddy, tin, dried and salted fish and fruit. It is included in the munton or circle named after the historic and once powerful province of Nakawn Si Tamaraj, north of the lake, and is the residence of the chief commissioner. The rainy season is much later than in Upper Siam, commencing towards the end of the south-west monsoon. When the north-east monsoon breaks in the China Sea in October the coast becomes a leeshore, and receives the full force of the gales which sweep against it. A high sea and heavy rains then prevail.

Sing Sing. The name of the village of Ossining (*q.v.*), Westchester county, New York, U.S.A., previous to 1901.

Sinkat. See EGYPT: *Military Operations.*

Sinnah. See KURDISTAN.

Sinope, now SINÚB, the chief town of a sanjak of the same name in the Kastamúni vilayet of Asia Minor, situated on the south shore of the Black Sea, on a low sandy isthmus which connects the promontory of Boz Tepe with the mainland. It has the only safe roadstead between the Bosphorus and Batum, but is shut off from the Anatolian plateau by high forest-clad mountains, over which there is no good road. It has little trade. The population consists of 5000 Moslems and 4000 Christians. The exports are about £80,000, and the imports £50,000.

Sion, or SITTEN, the capital of the Swiss canton of the Valais. It is on the railway between St Maurice (25½ miles distant) and Brieg (33 miles distant). Sion is one of the most picturesque little cities in Switzerland, being built around two prominent hillocks that rise from the level valley of the Rhône. The north hillock is crowned by the castle of Tourbillon (built 1294, burnt 1788), which was long the residence of the bishops. The south hillock bears the castle of Valeria, long the residence of the canons, with the interesting 13th-century church of St Catherine. In the town below is the 15th-century cathedral, and the majoria (burnt in 1788), the former residence of the "major" (or mayor of the city). There are various other curious objects in the city, which is built on the banks of the Sionne torrent, and is at a height of 1680 feet above the sea. In 1888 Sion contained 5424 (in 1900, 6095) inhabitants (mainly Roman Catholics), of whom 1969 were German-speaking and 3271 French-speaking.

Sion dates from Roman times (*Sedunum*), and the bishop's see was removed thither from Martigny (*Octodurum*) about 580. In 999 the bishop received from Rudolf III., King of Burgundy, the dignity of Count of the Valais, and henceforward was the temporal as well as spiritual lord of the Valais, retaining this position, at least in part, till 1798.

See J. GREMAUD. Introduction to vol. v. (Lausanne, 1884) of his *Documents relatifs à l'histoire du Vallais.*—R. R. HOPPELER. *Beiträge zur Geschichte des Wallis im Mittelalter*, Zürich, 1897. —B. RAMEAU. *Le Vallais Historique.* Sion, 1886.

(W. A. B. C.)

Sioux City, a city of Iowa, U.S.A., capital of Woodbury county. It is on the river Missouri, at the mouth of the Big Sioux, in the north-western part of the state, at an altitude of 1103 feet. The business portion of the city is in the bottom lands, while the residences are built upon the slope and summit of the cliffs. It has excellent water-supply and sewerage systems, is well paved, mainly with wood, and is divided into eight wards. It is a railway point of great importance, five railways meeting here—the Chicago, Milwaukee, and St Paul, the Chicago, St Paul, Minneapolis, and Omaha, the Illinois Central, the Great Northern, and the Sioux City and Pacific. These, with boats on the Missouri, give it a very large trade. In 1900 it had 329 manufacturing establishments, with a total capital of \$5,691,644. These employed 3104 hands, and the production was valued at \$15,469,702. Of this more than one-half was the product of slaughtering and meat-packing houses. Sioux City is the seat of Morningside College, a Methodist Episcopal institution, opened in 1890, which in 1899 had a faculty of 18 and was attended by 217 students. The assessed valuation of real and personal property was, in 1900, \$5,341,959, the net debt was \$2,176,013, and the rate of taxation 69·00 per \$1000, indicating a very low rate of assessment. Population (1890), 37,806; (1895), 27,371, showing a decided loss in the five years; (1900), 33,111, of whom 6592 were foreign-born and 280 negroes. Of 10,082 males 21 years of age and over, 117 were illiterate (could not write).

Sioux Falls, a city of South Dakota, U.S.A., capital of Minnehaha county. It is situated on the west bank of the Big Sioux, in the south-eastern part of the state, at an altitude of 1390 feet. The city has a regular plan, is divided into six wards, has good water-supply and sewerage systems, and is well paved. It is in a rich farming region, producing mainly wheat, for which this city is the shipping point. It has five railways, the Burlington, Cedar Rapids, and Northern, the Chicago, Milwaukee, and St Paul, the Chicago, St Paul, Minneapolis, and Omaha, the Wilmar and Sioux Falls branch of the Great Northern, and the Illinois Central. It has an excellent water-power in the Falls, which descend 100 feet in half a mile, and which have been utilized in flour-mills. Sioux City was incorporated as a town in 1877, and received a city charter in 1883. Population (1880), 2164; (1890), 10,177; (1900), 10,266, of whom 1858 were foreign-born.

Sipunculoidea.—The Sipunculoidea, formerly associated with the Echiuroidea (*q.v.*) in the group Gephyrea, are marine animals of uncertain affinities. Externally, the body of a Sipunculoid presents no projections: its surface is as a rule even, and often glistening, and the colour varies from whitish through yellow to dark brown. The anterior one-quarter or one-third of the body is capable of being retracted into the remainder, as the tip of a glove-finger may be pushed into the rest, and this retractile part is termed the introvert. At the tip of the introvert the mouth opens, and is surrounded in *Sipunculus* by a funnel-shaped, ciliated lophophore (Figs. 1 and 2). In *Phascolosoma* and *Phascolion* this funnel-shaped structure has broken up into a more or less definite group of tentacles, which in *Dendrostoma* are arranged in four groups. In *Aspidosiphon* and *Physcosoma* the tentacles are usually arranged in a horse-shoe, which may be double, overhanging the mouth dorsally. On the surface of the funnel-shaped lophophore are numerous ciliated grooves, and each of the tentacles in the tentaculated forms has a similar groove directed towards the mouth. These grooves doubtless serve to direct currents of water, carrying with them small organisms towards the mouth.

The skin consists of a layer of cuticle, easily stripped off, secreted by an ectodermal layer one cell thick. Within this is usually a sheath of connective tissue, which surrounds a layer of circular muscles; the latter may be split up into separate bundles, but more usually form a uniform sheet. Within the circular muscles is a layer of longitudinal muscles, very often broken into bundles, the number of which is often of specific importance. Oblique muscles sometimes lie between the circular and longitudinal sheaths. On the inner surface is a layer of peritoneal epithelium, which is frequently ciliated, and at the bases of the retractor muscles is heaped up and modified into the reproductive organs. The ectoderm is in some genera modified to form certain excretory glands, which usually take the form of papillæ with an apical opening. These papillæ give the surface a roughened aspect; the use of their secretion is unknown. They are best developed in *Physcosoma*.

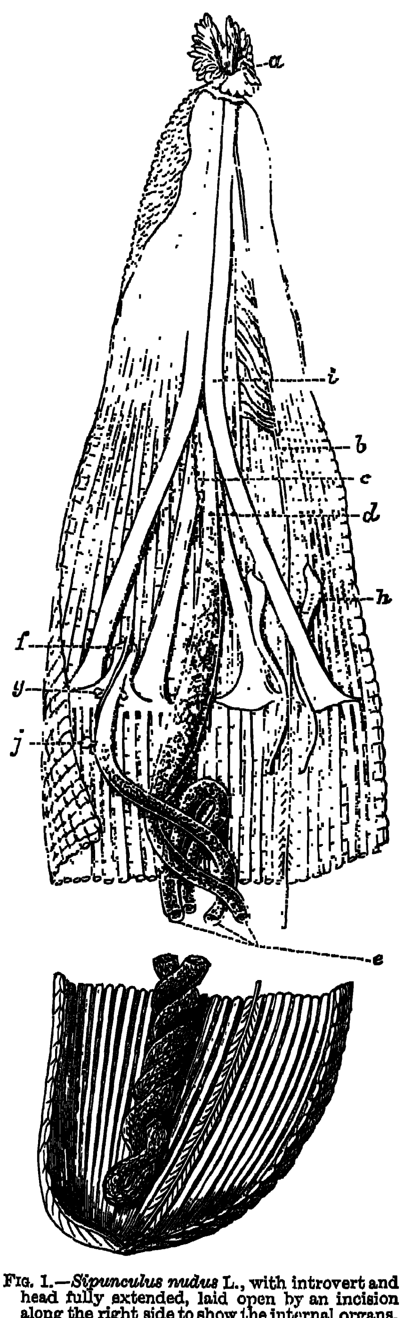

Fig. 1.—*Sipunculus nudus* L., with introvert and head fully extended, laid open by an incision along the right side to show the internal organs, ×2. *a*, mouth; *b*, ventral nerve-cord; *c*, "heart"; *d*, œsophagus; *e*, intestine; *f*, position of anus; *g*, tuft-like organs; *h*, right nephridium; *i*, retractor muscles; *j*, diverticulum on rectum. The spindle-muscle is seen overlying the rectum.

When the body of a Sipunculoid is opened, it is seen that the body-cavity is spacious and full of a corpusculated fluid, in which the various organs of the body float. The most conspicuous of these is the long, white alimentary canal, crowded with mud. The mouth is devoid of armature, and passes without break into the œsophagus; this is surrounded by the retractor muscles, which are inserted into the skin around the mouth, and have their origin in the body-wall, usually about one-third or one-half of the body-length from the anterior end (Figs. 1 and 2). Their function is to retract the introvert, which is protruded again by the contraction of the circular muscles of the skin; these, compressing the fluid of the body-cavity, force forward the anterior edge of the introvert, which in Lankester's

phraseology is pleurecbolic, acrembolic. The number of muscles varies from one (*Onchnesoma* and *Tylosoma*) to four, the latter being very common. The alimentary canal is U-shaped, the dorsal limb of the U terminating in the anus, situated not very far from the level of the origin of the retractor muscles. The limbs of the U are further twisted together in a looser or tighter coil, the axis of which may be traversed by a "spindle" muscle arising from the posterior end of the body. No glands open into the alimentary canal, but a diverticulum, which varies enormously in size, opens into the rectum. As is so often the case with animals which eat mud and sand, and extract what little nutriment is afforded by the organic débris therein, the walls of the alimentary canal are thin and apparently weak. All along one side is a microscopic ciliated groove, into which the mud does not seem to enter, and along which a continuous stream of water may be kept up. Possibly this is respiratory—there are no special respira-

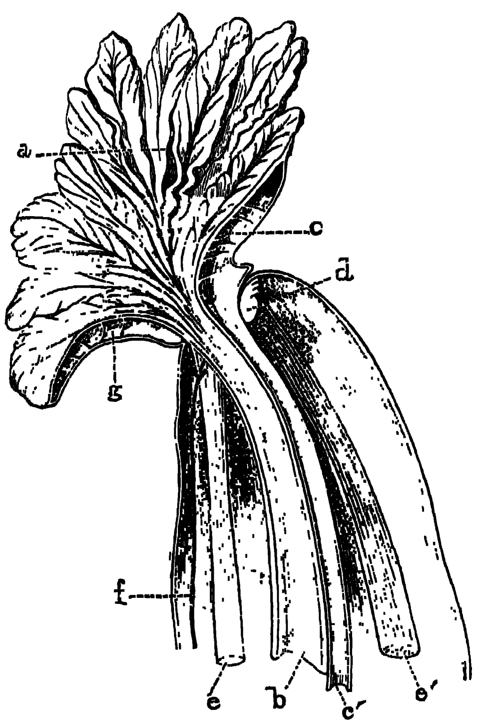

FIG. 2.—Right half of the anterior end of *Sipunculus nudus*, L., seen from the inner side and magnified. *a*, funnel-shaped grooved tentacular crown leading to the mouth; *b*, œsophagus; *c*, strands breaking up the cavity of the tentacular crown into vascular spaces; *c′*, "heart"; *d*, brain; *e*, ventral, and *e′*, dorsal retractor muscles; *f*, ventral nerve-cord; *g*, vascular spaces in tentacular crown.

tory organs. A so-called heart lies on the dorsal surface of the œsophagus; it is closed behind, but in front it opens into a circumœsophageal ring, which gives off vessels into the lophophore and tentacles. The contraction of this heart, which is not rhythmic, brings about the expansion of the tentacles and lophophore. This system is in no true sense a vascular system: there are no capillaries, and the fluid it contains, which is corpusculated, can hardly have a respiratory or nutritive function. It is simply a hydrostatic mechanism for expanding the tentacles. The excretory organs are typical nephridia, with an internal ciliated opening into the body-cavity, and an external pore. One surface of the tube is prolonged into a large sac lined with glandular, excretory cells. The organs are typically two, though one is often absent, *e.g.*, in *Phascolion*. They serve as channels by which the reproductive cells leave the body, and they are sometimes spoken of as "brown tubes." There is a well-developed brain dorsal to the mouth; this gives off a pair of œsophageal commissures, which surround the œsophagus and unite in a median ventral nerve-cord which runs between the longitudinal muscles to the posterior end of the body. From time to time it gives off minute circular nerves, which run round the body in the skin and break up into a very fine nerve plexus. There are no distinct ganglia, but ganglion cells are uniformly distributed along the ventral side of the cord. The whole is anteriorly somewhat loosely slung to the skin, so as to allow free play when the animal is extending or retracting its introvert. A pit or depression, known as "the cerebral organ," opens into the brain just above the mouth; this usually divides into two limbs, which are deeply pigmented and have been called eyes.

Sipunculoids are diœcious, and the ova and spermatozoa are formed from the modified cells lining the body-cavity, which are heaped up into a low ridge running along the line of origin of the retractor muscles. The ova and the mother-cells of the spermatozoa break off from this ridge, and increase in size considerably in the fluid of the body-cavity. Fertilization is external; and in about three days a small ciliated larva, not unlike that of the Echiuroids, but with no trace of segmentation, emerges from the egg-shell. This little creature, which has many of the features of a Trochosphere larva, swims about at the surface of the sea for about a month, and grows rapidly. At the end of this time it undergoes a rapid metamorphosis: it loses many of its larval organs, cilia, takes in a quantity of water into its body-cavity, sinks to the bottom of the sea, and begins life in its final form.

The following genera of Sipunculoids are recognized:—(i.) *Sipunculus*. This, with *Physcosoma*, has its longitudinal muscles divided up into some 17–41 bundles. It has no skin papillæ. The members of this genus attain a larger size than any other species, and the genus contains some 16–17 species. (ii.) *Physcosoma* (Fig. 3) has its body covered with papillæ, and usually numerous rows of minute hooks encircling the introvert. It is the most numerous genus, and consists for the most part of shallow-water (less than 50 fathoms) tropical and subtropical forms. They often live in tubular burrowings in coral-rock. The following three genera have their longitudinal muscles in a continuous sheath:—(iii.) *Phascolosoma*, with some 25 species, mostly small, with numerous tentacles. (iv.) *Phascolion*, 10 species, small, living in mollusc-shells and usually adopting the coiled shape of their house; only one kidney, the right, persists. (v.) *Dendrostoma*, with 4–6 tentacles, a small genus found in tropical shallow water. (vi.) *Aspidosiphon*, with 19 species, is easily distinguished by a calcareous deposit and thickened shield at the posterior end and at the base of the introvert, which is eccentric. (vii.) *Clœosiphon* has a calcareous ring, made up of lozenge-shaped plates, round the base of its centric introvert. (viii.) *Petalostoma*, a minute form with two leaf-like tentacles, is found in the English Channel. (ix.) *Onchnesoma*, with 2 species, and (x.) *Tylosoma*, with 1 species, have no tentacles, only one brown tube, and only one retractor muscle. Both genera are found off the Norwegian coast. The last named is said to have numerous papillæ and no introvert.

The *Priapuloidea*, a peculiar group of only three genera, *Priapulus*, *Priapuloides*, and *Halicryptus*, are usually placed in the neighbourhood of the Gephyrea, though there is little in their structure to warrant this classification. They are cylindrical worm-like animals, with a median anterior mouth quite devoid of any armature or tentacles. The body is ringed, and often has circles of spines, which are continued into the slightly protrusible pharynx. The alimentary canal is straight, the anus terminal, though in *Priapulus* one or two hollow ventral diverticula of the body-wall stretch out behind it. The

nervous system, composed of a ring and a ventral cord, retains its primitive connexion with the ectoderm. There are no specialized sense-organs or vascular or respiratory

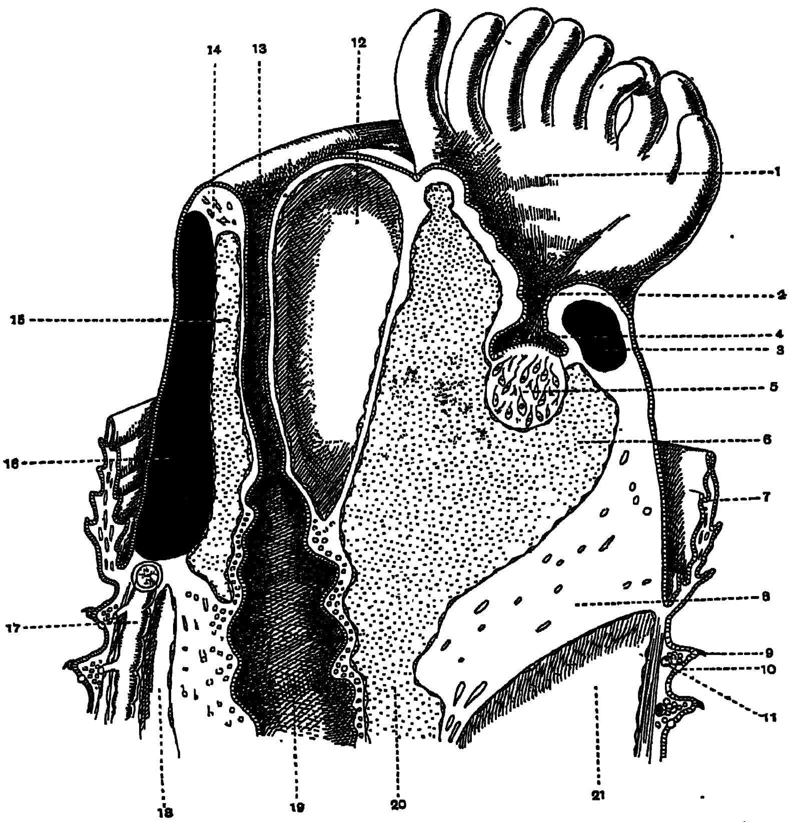

FIG. 3.—A semi-diagrammatic figure of the anterior end of half a *Physcosoma*, seen from the inner side. The introvert is fully everted and the lophophore expanded. The collar which surrounds the head is not fully extended. Two rows only of hooks are shown. 1, lophophore; 2, pigmented pit leading to brain; 3, section of dorsal portion of mesoblastic "skeleton"; 4, pit ending in eye; 5, the brain; 6, blood-sinus of dorsal side surrounding brain and giving off branches to the tentacles; 7, collar; 8, retractor muscle of head; 9, hook; 10, sense-organ; 11, nerve-ring; 12, cœlom of upper lip, it is continuous with 21; 13, mouth; 14, lower lip; 15, blood-sinus of ventral side, continuous with 6; 16, ventral portion of mesoblastic "skeleton"; 17, ventral nerve-cord; 18, cœlom, continuous with 12 and 21; 19, œsophagus; 20, dorsal vessel arising from the blood-sinus 6; 21, cœlom.

systems. The Priapuloidea are diœcious, and their male and female organs, which are one with the excretory organs, consist of a pair of branching tufts, each of which opens to the exterior on one side of the anus. The tips of these tufts enclose a flame-cell similar to those found in Platyhelminths, &c., and these probably function as excretory organs. As the animals become adult, diverticula arise on the tubes of these organs, which develop either spermatozoa or ova. These pass out through the ducts. Nothing is known of the development. The much-needed investigation of this point would probably throw some light on the affinities of the group. There are three genera: (i.) *Priapulus*, with the species *P. caudatus*, Lam., of the Arctic and Antarctic and neighbouring cold seas (Fig. 4), and *P. bicaudatus*, Dan., of the north Atlantic and Arctic seas; (ii.) *Priapuloides australis*, de Guerne, of the circum-polar waters of the south; and (iii.) *Halicryptus*, with the species

FIG. 4.—*Priapulus caudatus* Lam. Natural size. *a*, mouth, surrounded by spines.

H. spinulosus, v. Sieb., of northern seas. They live in the mud, which they eat, in comparatively shallow waters up to 50 fathoms.

Sirajganj, a town of British India, in the Pabna district of Bengal, on the right bank of the Jamuna or main stream of the Brahmaputra; 6 hours by steamer from the railway terminus at Goalundo. It is the chief river mart for jute in northern Bengal, with several jute presses and a jute mill. Population (1881), 21,037; (1891), 23,267.

Sirmur, or SARMOR (also called Nahan, after the chief town), a native state of India, within the Punjab. It occupies the lower ranges of the Himalaya, between Simla and Mussoorie. Area, 1108 square miles. Population (1881), 112,763; (1891), 124,134; (1901), 135,626, showing a continuous increase of about 10 per cent. in each decade. Estimated gross revenue, Rs.5,12,000; military force, 604 men. The chief, whose title is Raja, is a Rajput of high lineage. The Raja Shamsher Perkash, G.C.S.I., who died in 1898, ruled with remarkable ability and success. A younger son commanded the Imperial Service sappers in the Tirah campaign of 1896–97, and was rewarded with the rank of honorary captain in the Indian army and the distinction of C.I.E. Attempts have been made to establish an iron foundry, and to develop mines of slate and mica. The town of NAHAN is situated about 40 miles south of Simla, 3057 feet above the sea. The palace of the Raja and several other houses are built of stone in European style. Population (1881), 5253.

Sirohi, a native state of India, in the Rajputana agency. Area, 1966 square miles. Population (1881), 142,903; (1891), 188,977; (1901), 154,350, showing an increase of 30 per cent. in the earlier, but a decrease of 17 per cent. in the later period, due to the results of famine. Gross revenue (1896–97), Rs.4,21,587; tribute, Rs.6880. The chief, whose title is Maharao, is a Deora Rajput of the Chauhan clan, and claims descent from the last Hindu king of Delhi. The state is traversed by the Rajputana Railway. The town of SIROHI is 28 miles north of Abu-road station. Population (1881), 5699. It has manufactures of sword-blades and other weapons. The Crosthwaite Hospital, called after the late agent, which is built and equipped on modern principles, was opened by Sir Robert Crosthwaite in December 1897.

Sirsa, a town of British India, in the Hissar district of the Punjab, situated on a dry bed of the river Ghaggar; station on a branch of the Rajputana Railway, half-way between Rewari and Ferozepore. Population (1881), 12,292; (1891), 16,415; municipal income (1897–98), Rs.19,942. It occupies an ancient site, and was re-founded in 1837 as the headquarters of a British district, which was subdivided in 1884 between Hissar and Ferozepore. It is an important centre of trade with Rajputana, and has manufactures of cotton cloth and pottery.

Sis, the ancient *Sision*, the chief town of the Khozan sanjak of the Adana vilayet of Asiatic Turkey, situated on the left bank of the Girgen Su, a tributary of the Jihún, Pyramus, and at the south end of the important pass across Mount Taurus, which is followed by the road from Geuksún (*Kokusos*), to the Cilician plain and Adana. It was besieged by the Arabs in 704, and rebuilt in 1086 by Leo II., king of Lesser Armenia, who made it his capital. In 1374 it was taken and demolished by the sultan of Egypt, and it has never recovered its prosperity. It is the seat of an Armenian Katholikos, and the monastery and church built by Leo II. are interesting.

Sisterhoods (Modern Anglican).—The dissolution of religious houses in England (1536–1540) under Henry VIII. swept away more than 140 nunneries, and the Anglican Church was left without sisterhoods for three centuries. But as these had for 900 years formed part of her system, there were protests from time to time and attempts at restoration. Amongst such protests, which generally dwelt a good deal on the want of provision for unmarried women, may be mentioned three in successive centuries. The historian Fuller would have been glad "if such feminine foundations had still continued," those "good shee-schools," only without vows (Bk. vi.). Richardson the novelist, in *Sir Charles Grandison*, wishes there could be a Protestant nunnery in every county, "with a truly worthy divine, at the appointment of the bishop of the diocese, to direct and animate the devotion of such a society"; in 1829 the poet Southey, in his *Colloquies* (cxiii.), trusts that "thirty years hence this reproach also may be effaced, and England may have its Béguines and its sisters of mercy. It is grievously in need of them." Also small practical efforts were made in the religious households of Nicholas Ferrar at Little Gidding, 1625, and of William Law at King's Cliffe, 1743; and under Charles II., says Fr. Bede, *Autob.*, "about 12 Protestant ladies of gentle birth and considerable means" founded a shortlived convent, with Sancroft, then Dean of St Paul's, for director.

Southey's appeal had weight, and before the thirty years had passed, compassion for the needs of the destitute in great cities, and the impulse of a strong Church revival, aroused a body of laymen, among whom were included Mr Gladstone, Sir T. D. Acland, Mr A. J. Beresford-Hope, Lord Lyttelton, and Lord John Manners (chairman), to exertions which restored sisterhoods to the Church of England. On 26th March 1845 the Park Village Community was set on foot in Regent's Park, London, to minister to the poor population of St Pancras. The "Rule" was compiled by Dr Pusey, who also gave spiritual supervision. In the Crimean war the superior and other sisters went out as nurses with Florence Nightingale. The community afterwards united with the Devonport Sisters, founded by Miss Sellon in 1849, and together they form what is known as Ascot Priory. The St Thomas's sisterhood at Oxford commenced in 1847; and the present mother-superior of the Holy Trinity Convent at Oxford, Marian Hughes, dedicated herself before witnesses to such a life as early as 1841 (Liddon's *Life of Dr Pusey*, iii.).

Four sisterhoods stand together as the largest: those of Clewer, Wantage, All Saints, and East Grinstead; and the work of the first may stand as a specimen of that of others. The "Community of St John the Baptist" at Clewer, near Windsor, arose in 1849 through the efforts of Mrs Tennant and the vicar, afterwards warden of the society, the Rev. T. T. Carter, to save fallen women. Under the first superior, Harriet Monsell, the numbers grew apace, and are now above 200. Their services to society and the Church include 6 houses for fallen women, 7 orphanages, 9 elementary and high schools and colleges, 5 hospitals, mission work in 13 parishes, and visiting in several "married quarters" of barracks. Many of these are important institutions, and their labours extend over a wide area; two of the settlements are in India, and two in the United States. A list of 26 sisterhoods is given in the *Official Year-Book of the C.E.*, 1900, to which may be added 10 institutions of deaconesses, many of whom live in community under rule. The Episcopal Church of Scotland has 3 sisterhoods; and they are found also at Toronto, "Saint John the Divine"; Brisbane, "Sacred Advent"; Grahamstown, "Resurrection"; Bloemfontein, "St Michael and All Angels"; Maritzburg, "Saint John the Divine." The *Year-Book* of the Protestant Episcopal Church of America (Anglican) mentions 17 American sisterhoods and 7 deaconess homes and training colleges.

Practically all Anglican sisterhoods originated in works of mercy, and this fact largely accounts for the rapidity with which they have won their way to the good-will and confidence of the Church. Their number is believed to exceed 3000, and the demand for their services is greater than the supply. Bishops are often their visitors, and Church Congresses, Convocation, and Lambeth Conferences have given them encouragement and regulation. This change in sympathy, again, has gained a hearing from modern historians, who tend more and more to discredit the wholesale defamation of the dissolution period. This charitable activity, however, distinguishes the modern sister from the nuns of primitive and mediæval times, who were cloistered and contemplative, and left external works to deaconesses, or to laywomen of a "third order," or to the freeer societies like the Béguines. St Vincent de Paul is considered to have begun the new era with his institution of "Sisters of Charity" in 1634. Another modern feature is the fuller recognition of family ties: Rule 29 of the Clewer sisters directs that "the sisters shall have free intercourse with relations, who may visit them at any time." But in most essential respects modern sisterhoods follow the ancient traditions. They devote themselves to the celibate life, have property in common, and observe a common rule of prayer, fellowship, and work. Government is by a sister-superior, assisted by various officers. The warden and chaplain are clergy, and the visitor is commonly a bishop. In one important regard there has been hesitation, and authorities like Dr Littledale and Bishop Grafton contend strongly for the primitive ideal of the convent as family, with a constitutional government, as against the later and widespread Jesuit ideal of the convent as regiment, with a theory of despotic rule and absolute obedience. If some early mistakes in the restoration of sisterhoods were due to this exaggerated doctrine of obedience, the doctrine itself may be trusted to disappear among a Church and people accustomed to free institutions and to respect for individuality.

Sistova, or Sistow, chief town of a department of Bulgaria, on the right bank of the Danube, 40 miles above Rustchuk. It has improved considerably in prosperity since the Russian war of 1878, notwithstanding a large migration of the Turkish population, and has a considerable trade in corn and wine. A Russian petroleum depôt has been established. The exports in 1897 amounted to 30,261 tons, valued at £132,961, and the imports to 26,296 tons, valued at £207,601; and in 1900 the exports and imports amounted respectively to only 17,295 tons, valued at £94,520, and 15,065 tons, valued at £91,691. Population (1892), 13,212.

Sitapur, a town and district of British India, in the Lucknow division of Oudh. The town is on the river Sarayan, half-way between Lucknow and Shahjahanpur; railway station, 55 miles north-west from Lucknow. Population (1881), 18,544; (1891), 21,380; municipal

income (1897–98), Rs.30,592, less than half from octroi; incidence of taxation, R.0.12.6 per head; registered death-rate (1897), 61·5 per thousand. It is still a cantonment, with a European regiment. It has a high school and printing-press.

The district of SITAPUR has an area of 2255 square miles. Population (1881), 958,251; (1891), 1,075,413, showing an increase of 12 per cent.; average density, 477 per square mile. In 1901 the population was 1,175,579, showing an increase of 9 per cent. The land revenue and rates are Rs.15,34,427, the incidence of assessment being just R.1 per acre; cultivated area (1896–97), 874,472 acres, of which 121,608 were irrigated from wells and tanks; number of police, 1490; vernacular schools, 159, with 5811 pupils; registered death-rate (1897), 36·6 per thousand. The principal crops are rice, pulse, wheat, barley, sugar-cane, and opium. The district is traversed by the Lucknow–Bareilly section of the Rohilkhand and Kumaon Railway. There are no Government canals.

Sitka, formerly Novo Arkhangelsk, the most notable town of S.E. Alaska, situated on Sitka Sound on Baranoff Island, in 57° 03′ N. and 135° 20′ W. Founded in 1804 by Lisianski and Baranoff, after the destruction of an earlier trading post (1800–04) in a less defensible situation, it was until 1867 the chief port and seat of government of Russian America, a fortified trading-post, with churches, a seminary, library, shipyard, foundries, and all the belongings of a great mercantile corporation under military discipline. Since the purchase of Alaska it has continued to be the seat of government and of the United States courts, though its commercial importance has diminished relatively to other towns in Alaska. The transfer of the territory took place at Sitka (18th October 1867). The settlement, besides Government buildings, comprises a large Indian village of frame houses, as well as numerous magazines, shops and dwellings of the white population, a saw-mill, a Greek church and mission school, a large Presbyterian school and mission, and an ethnological museum. In the vicinity are numerous mines of gold and silver. The extinct volcano Mount Edgecumbe is a conspicuous landmark across the Sound. The population in 1890 was 300 whites and 893 natives; in 1900 the total population was 1396. The mean annual temperature of Sitka is 43·3° F.; rainfall 81·7 inches. The prevailing winds are from the south and east.

Sittingbourne, a market-town in the Faversham parliamentary division of Kent, England, on a creek of the Swale, 16 miles by rail west by north of Canterbury. Modern buildings are a free library, a Masonic hall, and public baths. Area of parish (an urban district), 1004 acres. Population (1881), 7856; (1901), 8944.

Siut. See ASSIUT.

Sivaganga, a town of British India, in the Madura district of Madras; situated in 9° 51′ N. and 78° 32′ E., 25 miles east of Madura. Population (1891), 8800. It contains the residence of a *zamindar*, whose estate covers an area of 1220 square miles and pays a permanent land revenue of £25,864. The succession has been the subject of prolonged litigation. There is a high school.

Sivas.—(1) One of the largest and most important vilayets of Asia Minor, lying between 38° 30′ and 41° N. and 35° 30′ and 39° E. It is divided into four sanjaks—Sivas, Tokat, Amásia, and Shabin Kara-hissar; has an area of 32,300 square miles, and a population of 1,090,000 (Moslems, 840,000, of whom one-third are Kizilbash; Armenians, 172,000; Greeks, 78,000). The vilayet is rich in mineral wealth—silver, lead, copper, iron, manganese, arsenic, alum, salt, and coal; has several hot and cold mineral springs; and large forests of fir, pine, beech, and oak. The climate is good, and the soil fertile. Wheat and barley are largely grown on the plateau, and in the lower districts there are extensive fruit orchards and vineyards. The port of the vilayet is Samsún, whence a *chaussée* runs through Amasia, Tokat, and Sivas to Kharpút. The exports in 1900 amounted to £422,175, and the imports to £502,506; the principal items in the former being grain and flour, opium, textiles, tobacco, wool, live stock, and carpets, while cotton goods represent 28 per cent. of the imports.

(2) The chief town of the vilayet and of a sanjak of the same name, the ancient *Sebasteia*, altitude 4420 feet, situated in the broad valley of the Kizil Irmak, on one of its tributaries, the Murdan Su. The climate is healthy, but severe in winter. Coarse cotton cloth and woollen socks are manufactured. The *medresses*, or colleges, built in the 13th century by the Seljúk sultans of Rúm, are amongst the finest remains of Seljúk art in Asia Minor. In one of them is the tomb of its founder, Izz-ed-dín Kai Káús I. (1210–19). Near the town is the Armenian Monastery of the Holy Cross, in which are kept the throne of Senekherim and other relics. There are several Armenian churches of interest, a flourishing American mission with church and schools, and a Jesuit mission. Population, Moslems, 33,000; Armenians, 9000; Greeks, 2000. Sebasteia was the name given under the early empire to an unknown place, which had been called Megalopolis by Pompey. Under Diocletian it became the capital of Armenia Minor, and in the 7th century that of the Sebasteia Theme. Justinian rebuilt the walls and, under the Byzantine emperors, it was second only to Cæsarea in size and wealth. In 1021 Senekherim, king of the Armenian province of Vaspuragan (Van), ceded his dominions to Basil II., and became the Byzantine viceroy of Sebasteia and the surrounding country. This position was held by his successors until the town fell into the hands of the Turkomans after the defeat, 1071, of Romanus II. by the Seljúks. After having been ruled for nearly a century by the Danishmand Emirs, it was taken, 1172, by the Seljúk sultan of Rúm, and in 1224 was rebuilt by Sultan Ala-ed-dín Kai Kubad I. In 1400, when captured by Timúr, the city is said to have had 100,000 inhabitants. On this occasion the bravest defenders were massacred, and 4000 Armenians were buried alive. From this disaster Sivas never recovered. In November 1895 most of the Armenians of wealth and influence were massacred. Mekhitar, the founder of the Mekhitarist Order and of the famous monastery at Venice, was born (1676) at Sivas. (C. W. W.)

Sivori, Ernesto Camillo (1815–1894), Italian violinist, was born at Genoa 25th October 1815, and was taught by Restano and Costa until, when he was about six years old, Paganini heard him play, and was so impressed that he wrote a concertino for violin, guitar, viola, and violoncello, in which the composer used to play the guitar part. From 1827 Sivori began the career of a travelling virtuoso, which lasted almost without interruption until 1864. He played Mendelssohn's concerto for the first time in England, in 1846, and was in England again in the seasons of 1851 and 1864. He lived for many years in Paris, and died at Genoa 18th February 1894. He was the recognized successor of Paganini, and his playing possessed all the qualities that distinguish the virtuoso.

Sivri-Hissar, the ancient *Justinianopolis-Palia*, a town of Asia Minor, in the Angora vilayet, situated 8 miles north of the site of Pessinus. It is a road and commercial centre, with a trade in opium and mohair. The population includes a large Armenian community. Justinianopolis was one of the strong places on the Byzantine military road, and became the chief city of Galatia Salutaris, and the seat of a metropolitan who held the title of archbishop of Pessinus.

Skagerrack, an arm of the North Sea giving access to the Cattegat, whilst northwards it forms Christiania Fjord. (For the currents, temperature, and salinity of the water, &c., see NORTH SEA.)

Skagway, a town in S.E. Alaska at the mouth of the river of the same name, in 59° 27′ N. and 135° 16′ W., on an indentation of Taiya Inlet, a branch of Chilkoot Inlet, leading out of Lynn Canal. This settlement was made in 1895, though individuals had squatted there earlier. It originated in the rush for the Klondike gold-fields, for which Skagway is the most convenient entrance, by the trail over the lower of the two passes to the head-waters of the Yukon. After a stormy beginning, due to the usual mixed population of a community of diggers, Skagway has steadily grown in population, business, and good order. It has water-works, churches, schools, &c., and being the seaward termination of the Yukon and White Pass Railway, by which goods and passengers reach the Klondike, its prosperity seems assured. In 1900 the population was 3117. It is connected with Dawson by telegraph, and with the outside world by frequent steamers.

Skating.—Development in both branches of skating, speed and figure, was great in the later years of the 19th century. The pastime profited both by increasing devotion to athletics and by increased facilities of communication, which led to international competitions, interchange of ideas, and the institution of skating clubs in Switzerland and elsewhere, especially those of Davos, St Moritz, and Grindelwald, where ice is available every winter. Although skating instruments are so simple, the evolution of the skate has advanced considerably, contributing to marked improvement in the skater's skill. In *speed-skating* an epoch was marked, first, by the almost universal adoption of the Norwegian type of racing skate; and, secondly, by the institution in 1892, at an international congress held in Holland, of annual races for the championships of Europe and of the world.

(i.) The Norwegian skate, introduced and perfected (1887–1902) by Axel Paulsen and Harald Hagen, is constructed with a view to lightness, strength, and diminution of friction. The blade, of specially hardened steel, is set in a hollow horizontal tube of aluminium, and connected by similar vertical tubes with foot-plates riveted to a closely-fitting boot with thin leather sole. It is 16–17¾ inches long and ½–2 millimetres thick (*i.e.*, ·019–·078 inch), the average employed for hard ice being ¾ mm., often thinner towards the heel. This thickness is suitable for good English ice, but for softer ice $\frac{1}{16}$ or $\frac{3}{32}$ inch is preferable. The blade is flat on the ice throughout, except for an inch in front; this flatness distributes the weight, and with the extreme thinness of blade reduces friction to a minimum. The edges are right-angled and sharp.

The skater's style has been modified. The blade, when planted on the ice with weight upon it, describes a nearly straight line, the last few feet only curving slightly outwards as the skate leaves the ice. Hence the stroke of the best modern skaters is almost, if not entirely, on the inside edge, a gain in directness and speed, the outside edge being used for curves only. The length of stroke has tended to diminish. Contrasted with the 12–18 yards' stroke attributed to the old English champion, W. "Turkey" Smart, which was partly on the outside edge, the modern racing stroke rarely exceeds 10 yards, and is usually nearer 6 or 7. Particular instances vary with conditions of ice, &c., but at St Petersburg, in 1896, Eden's stroke in the 10,000 metre race averaged about 7½ yards, that of P. Oestlund at Davos in 1900, the same (for one lap, 8 yards). J. F. Donoghue's stride in 1891 was computed at about 6 yards. The general effect has been vastly increased speed, and a conjoint cause is the stricter training undergone before important races.

(ii.) The races held annually since 1892–93 for the championships of Europe and of the world, under the auspices of the International Skating Union, have assembled representatives from the skating countries of Europe and from America; but up to 1902, after the victorious career of Mr J. F. Donoghue through Europe in 1890–91, Americans rarely competed in Europe, though America has produced some remarkably fine skaters, such as J. L. Johnson and Nilsson; while England, through lack of ice for practice, has fallen somewhat behind in skill, and up to 1902 entered but a single representative for the world's championship, Mr C. Edgington (Oxford University), who from 1899 held successfully against the foreigners the only world's record made in recent years by an Englishman, viz., 19 miles 348 yards in an hour. Hence the struggle lies usually between Norway, Sweden, Germany, Austria, Hungary, Holland, Finland, and Russia. France has produced no speed-skater of note except M. G. de Stoppani.

The professional championship was held in 1893–94 at Zwolle, in Holland, and was won by H. Hagen (Norway), but since then has lapsed. The winners of the world's amateur championship are as follow:—

Date.	Place.	Name.	Nationality.
1892–93 .	Amsterdam	J. Eden	Holland
1893–94 .	Stockholm	Not decided	...
1894–95 .	Hamar	J. Eden	Holland
1895–96 .	St Petersburg	J. Eden	„
1896–97 .	Montreal	J. K. McCulloch	Canada
1897–98 .	Davos	P. Oestlund	Norway
1898–99 .	Berlin	P. Oestlund	„
1899–1900 .	Christiania	E. Engelsaas	„
1900–01 .	Stockholm	F. Wathén	Finland
1901–02 .	Helsingfors	Not decided *	...

* R. Gundersen (Norway) won two races only.

The races are four in number, over distances of 500, 1500, 5000, and 10,000 metres, and to obtain the title of champion a skater must win three races and finish in the fourth. In addition, each country, when possible, holds its own championship races. The English champions for 1899–1900 were A. E. Tebbit (amateur) and F. Ward (professional); and for 1901–2, A. E. Tebbit and J. Bates; but the National Skating Association was prevented by unsuitable weather from holding the races from 1895–1900.

In England races are still skated, with rare exceptions, on straight courses, with a sharp turn round a post or barrel, the distance prescribed for N.S.A. championships being 1½ miles with three turns. The Continental and international system involves a course with straight sides and curved ends of such a radius that no slackening of speed is necessary. In both instances the competitors race two at a time on a double track, and the time test is used. Each skater must keep his own course, to prevent either from using the other as pacemaker or wind-shield. The international regulations (*Eiswettlauf Ordnung*) prescribe that, if a single track be used, the hindmost skater must keep at a minimum distance of 5 metres from the other, on pain of disqualification. The advantage of inner curve on a Continental course is given alternately, and a space left open between the tracks at one point for the skaters to cross.

The curves are skated with a step-over-step action, and the direction is always from right to left. Hence, on entering the curve the right foot is brought across in front and set down on the inside edge, the left passing behind on the outside edge, and being in its turn set down on an outside edge in front. The strokes thus form a series of tangents to the curve, and are little shorter than in the straight. With a radius of 25 and 30 metres, as at Davos, the curves can be skated with safety at full speed. Skating records are somewhat confused, varying widely with conditions and form of track. The world's records for the four championship distances up to 1902 were:—

Distance.	Time.		Holder and Nationality.	Place and Date.
Metres.	min.	secs.		
500 (=547 yds.) . .	0	45⅕	P. Oestlund (Norway)	Davos, 1900
1500 (=1640 yds.) . .	2	22⅗	„ „	„ „
5000 (=3 miles 188 yds.)	8	37⅗	J. Eden (Holland)	Hamar, 1894
10,000 (=6 miles 376 yds.)	17	50⅗	P. Oestlund (Norway)	Davos, 1900

For other distances and times, cf. *The Field* (*passim*); *Sporting*

and Athletic Records, by H. Morgan-Browne (1897); *The Sportsman's Year-Book*, 1899; *The Spirit of the Times*, W. Curtis (New York); *The Badminton Magazine*, January 1900; *Whitaker's Almanac.*

Figure-skating has received a great impetus—

(i.) In England, (*a*) from the multiplication of clubs, *e.g.*, Wimbledon (founded 1870), Thames Valley, Crystal Palace, &c., in addition to the original "Skating Club" and those in Switzerland already mentioned; and from the construction of numerous artificial rinks, such as "Niagara" and the "National Skating Palace"; (*b*) from the encouragement afforded by the National Skating Association, which offers 1st, 2nd, and 3rd class badges (and a special or "Diamond" badge for figure-skating) for figure tests, as well as for speed; and in 1893 founded a "London Skating Council," while in 1898 and in 1902 it held the figure-skating championship of the world in London. The N.S.A. has, however, occupied an anomalous position, holding international competitions in Continental style, while encouraging a style which in itself disqualifies Englishmen from competing.

(ii.) Abroad, from increased organization and the institution of rinks and minor competitions in every important town, in addition to the amateur championships of Europe and of the world held by the International Skating Union.

Thus figure-skating also has developed on international lines, and two separate styles or schools have been evolved, English and Continental, based no doubt on variety of national temperament; the distinctive features of the latter being use of arms and "unemployed" leg, and the bending of the knee, which in the English school are rigidly forbidden. The foreign school was founded by Jackson Haynes, an American professional and accomplished dancer, and is the more showy and seemingly the more graceful, the English being the more severe and the more self-restrained, but bolder and stronger, having for its object not an individual display, but perfect skating in combination. There are, of course, local modifications, the strictest exponents of the English school being the Davos and St Moritz skaters, while the Continental varies from the complete *abandon* of the French to the more restrained style of the Germans; Canadians cultivate also grape-vines and other two-footed figures. The essential features are, however, identical. Thus Englishmen consider of secondary importance loops, cross-cuts, continuous and hand-in-hand skating, though such figures are included in the 1st class test of the N.S.A., and devote themselves mainly to "combined figures." Combined figures have been defined as "symmetrical execution of a figure by one or more pairs of skaters." Originally known as the "skating club figures," they have been gradually developed, and in 1891 delegates from the principal clubs established a regular terminology. The ideal number of skaters for a combined figure is four, though sixes and eights are seen, one being chosen "caller" of the movement to be skated. Various sets of "calls" are arranged at the discretion of different clubs, and consist ordinarily of "turns" and "changes." The N.S.A. offer a challenge shield for an annual competition in combined figure-skating. There has of late, however, been a marked tendency towards unification of style, through Englishmen adopting Continental methods, rendered almost a necessity by the circumscribed area of artificial rinks. In 1901 the Figure Skating Club was established for this purpose, and its members attained such success that an English lady, Mrs Syers, gained the second place in the world's championship competition in 1902, and with her husband won the International Pair Skating.

Continental skating culminates in the annual meeting for the amateur championship of the world, which was won by Herr Grenander (Stockholm), 1898, Herr G. Hügel (Vienna), 1899 and 1900, and Herr U. Salchow (Stockholm), 1901 and 1902. The competition consists of two parts, (*a*) compulsory figures, (*b*) free skating, the latter affording scope for the performance of dance steps and brilliant individual figures, such as the "sitting pirouette," of which Herr Hugel is master, and the "star," consisting of four crosses (forward rocker, back loop, back counter), invented by Herr Engelmann and splendidly rendered by Herr Salchow.

As in speed-skating, important professional meetings are almost non-existent.

The skates used for the English and Continental styles differ in radius, though both are of the same type, *i.e.*, a blade fastened to the boot by sole-plates, the "Mount Charles" pattern being the one generally adopted by Englishmen. The English radius is 7 ft., or now more usually 6 ft.; the foreign, 5½ or even 5 ft., and the result is seen in the larger curves skated on the former, and the greater pace obtained owing to decreased friction; at the same time, the difficulty of making a turn is greater. The English skate has generally right-angled edges and blade of same thickness throughout, except in the "Dowler" variety, which is thicker towards the extremities. The foreign skate is sometimes thicker in the middle than at the ends.

Skeat, Walter William (1835——), English philologist, was born in London, 21st November 1835, and educated at King's College, Highgate Grammar School, and Christ's College, Cambridge, of which he became a fellow in July 1860. In 1878 he was elected Ellington and Bosworth Professor of Anglo-Saxon at Cambridge. He completed Mitchell Kemble's edition of the Anglo-Saxon Gospels, and did much other work both in Anglo-Saxon and in Gothic, but is perhaps most generally known for his labours in Middle English, and for his standard editions of Chaucer and Piers Plowman. As he himself generously declared, he was at first mainly guided in the study of Chaucer by Henry Bradshaw, with whom he was to have participated in the edition of Chaucer planned in 1870 by the University of Oxford, having declined in Bradshaw's favour an offer of the editorship made to himself. Bradshaw's perseverance was not equal to his genius, and the scheme came to nothing for the time, but was eventually resumed and carried into effect by Professor Skeat in an edition of seven volumes, the last of which was published in 1897. He also issued an edition of Chaucer in one volume for general readers, and a separate edition of his *Treatise on the Astrolabe*, with a learned commentary. His standard edition of Piers Plowman was published in 1886, and, besides the *Treatise on the Astrolabe*, he edited numerous books for the Early English Text Society, including Barbour's *Bruce* and the romances of *Havelock the Dane* and *William of Palerne.* For the Scottish Text Society he edited *The King's Quair*, usually ascribed to James the First of Scotland, and he published an edition of Chatterton, with an investigation of the sources of the obsolete words employed by him. In pure philology Professor Skeat's principal achievement is his *Etymological English Dictionary*, the most important of all his works, which must be considered in connexion with the numerous publications of the English Dialect Society, in all of which, even when not edited by himself, he had a hand as the society's director and afterwards its president. He is also the author of a work on the principles of English etymology, and of a volume of essays entitled *A Student's Pastime*, besides minor matters too numerous to mention. No modern scholar has laboured more assiduously, or produced a larger amount of first-class work.

Skegness, a popular bathing-resort in the South Lindsey, or Horncastle, parliamentary division of Lincolnshire, England, 20 miles north-east of Boston. Since 1873,

when railway connexion was given with Firsby on the Lincolnshire loop line, the place has undergone a complete transformation, and possesses now broad tree-shaded streets, a marine promenade, public gardens, good hotels, a cricket ground, golf links covering 400 acres, and a long pier, opened in 1881. There are broad, firm sands, on which account Skegness is much visited. On bank holidays and similar holidays several thousands of excursionists are poured over the sands from the manufacturing towns of Yorkshire, Nottinghamshire, Derbyshire, Leicestershire, and Lancashire. Since 1894 it has been governed by an urban district council. Population of the urban district (1891), 1488; (1901), 2140.

Skien, a seaport town of Norway, county of Bratsberg, on the south coast, on the river Skien, 5 miles below its issue from Lake Nord, and 6 miles above its outflow into Frier Fjord. It has been mostly rebuilt since a fire in 1886. Here Henrik Ibsen, the dramatist, was born in 1828. In 1892 a canal, nearly 50 miles long and ascending 189 feet by means of 15 lochs, was made between Lakes Bandak and Nord. In the town and district are numerous saw-mills, planing-, cotton-spinning-, and flour-mills, factories for wood-pulp, furniture, ironmongery, paper, bleaching-powder, calcium carbide, tobacco, hosiery, shoes, butter, candles and soap, also a copper mine (at Omdal). The total trade approximates to half a million sterling (£173,000 in 1887); the exports being ice, timber (telegraph poles for the British Government), wood-pulp, and copper, and the imports coal and china-clay. In 1898 the port was entered and cleared by vessels of an aggregate of 123,100 tons. Population (1891), 8979; (1900) 11,343.

Skin. See PATHOLOGY: *Skin*.

Skipton, a parish and market-town in the Skipton parliamentary division of Yorkshire, England, on the Aire, 18 miles north-east of Bradford by rail. Science and art schools have been erected. There are extensive woollen and cotton factories, and, in the neighbourhood, a large limestone quarry. Area of township (an urban district), 4245 acres. Population (1891), 10,376; (1901), 11,986.

Skobeleff, Michael Dimitriévitch (1843–1882), Russian general, was born near Moscow on 29th September 1843. After graduating as a staff officer at St Petersburg he was sent to Turkestan in 1868 and, with the exception of an interval of two years, during which he was on the staff of the Grand Duke Michael in the Caucasus, remained in Central Asia until 1877. He commanded the advanced guard of General Lomakine's column from Kinderly Bay, in the Caspian, to join General Verefkin, from Orenburg, in the expedition to Khiva in 1874, and, after great suffering on the desert march, took a prominent part in the capture of the Khivan capital. Dressed as a Turkoman, he intrepidly explored in a hostile country the route from Khiva to Igdy, and also the old bed of the Oxus. In 1875 he was given an important command in the expedition against Khokand under General Kaufmann, showing great capacity in the action of Makram, where he outmanœuvred a greatly superior force and captured 58 guns, and in a brilliant night attack in the retreat from Andijan, when he routed a large force with a handful of cavalry. He was promoted to be major-general, decorated with the order of St George, and appointed the first Governor of Fergana. In the Turkish war of 1877 he seized the bridge over the Sereth at Barborchi in April, and in June crossed the Danube with the 8th Corps. He commanded the Caucasian Cossack Brigade in the attack of the Green Hills at the second battle of Plevna. He captured Lovtcha on 3rd September, and distinguished himself again in the desperate fighting on the Green Hills in the third battle of Plevna. Promoted to be a lieutenant-general, and given the command of the 16th Division, he took part in the investment of Plevna and also in the fight of 9th December, when Osman Pasha surrendered, with his army. In January 1878 he crossed the Balkans in a severe snowstorm, defeating the Turks at Senova, near Schipka, and capturing 36,000 men and 90 guns. Dressed with care in white uniform and mounted on a white horse, and always in the thickest of the fray, he was known and adored by his soldiers as the "White General." He returned to Turkestan after the war, and in 1880 and 1881 further distinguished himself in retrieving the disasters inflicted by the Tekke Turkomans, captured Geok-Tepe, and, after much slaughter, reduced the Akhal-Teke country to submission. He was advancing on Askabad and Kalat i-Nadiri when he was disavowed and recalled. He was given the command at Minsk. In the last years of his short life he engaged actively in politics, and made speeches in Paris and in Moscow in the beginning of 1882 in favour of a militant Panslavism, predicting a desperate strife between Teuton and Slav. He was at once recalled to St Petersburg. He was staying at a Moscow hotel, on his way from Minsk to his estate close by, when he died suddenly of heart disease on 7th July 1882. (R. H. V.)

Skopin, a district town of Russia, in the government of Ryazañ, 23 miles by rail from Ryazhsk junction. It is a very old town, which is now a great centre for trade in corn, hemp, oil, meat, cattle, and salt exported to Moscow, and in hardware goods imported both from the capital and from Nijni-Novogorod. It has several flour-mills, oil-mills, tanneries, and soap-works. Population (1897), 14,737.

Skowhegan, a town of Maine, U.S.A., capital of Somerset county. It is on the river Kennebec 35 miles above Augusta, and on a line of the Maine Central Railroad. Using the ample water-power furnished by the river, it has manufactures of varied character. Population (1880), 3869; (1900), 4266, of whom 480 were foreign-born.

Skram, Erik. See DANISH LITERATURE.

Skye, the largest island of the Inner Hebrides, Scotland, lying between 57° 1′ 12″ and 57° 42′ 39″ N. and 5° 38′ 50″ and 6° 47′ 8″ W. The sheep farms include some of the finest in Scotland, carrying famous stocks. The crofters succeed best with turnips and potatoes. Since the passing of the Crofters Act in 1886, the old black huts have been largely replaced by well-built houses in those parishes where stone is obtainable, and more attention is being paid to cleanliness in the home. The opening of an extension of the Highland Railway has brought the fishing grounds somewhat closer to the markets. In 1899 the value of the fish caught in the Skye district was £159,988. Diatomite is found in the island, and is used for the manufacture of explosives. A stone pier has been built at Broadford. There is a fever hospital, a court house and resident sheriff-substitute, and a tweed factory, at Portree, near which town stands the combination poorhouse of the island. Population of the island (1891), 15,705; (1901), 14,608.

Slagelse, a town of Denmark, county Sorö, island of Zealand, 58 miles by rail west-south-west of Copenhagen. It is one of the oldest towns of the kingdom, and was mentioned in the 12th century. In the vicinity are the ruins of the Knights Hospitallers' monastery of Antvorskov. Population, (1880), 6076; (1901), 8958.

Slatina, chief town of the district of Olt, Rumania, 87 miles west of Bucharest, on the river Olt or Alutha.

It has nine churches, of which the most remarkable is that of St Jonascu. The town is very ancient. Population (1895), 6500; (1900), 8028.

Slaughter-House, or ABATTOIR.—In the United Kingdom slaughter-houses are of two kinds, those which belong to individual butchers and those which belong to public authorities; the former are usually called private slaughter-houses, the latter public slaughter-houses. Private slaughter-houses in existence in England before the passing of the Public Health Act, 1875, were established without licence by the local authority, except in those towns to which the provisions of the Towns Improvement Clauses Act, 1847, relating to slaughter-houses, were applied by special Act. By the Act of 1875 these provisions were extended to all urban districts. Subsequently to 1890 urban authorities adopting Part III. of the Public Health (Amendment) Act of that year could license for limited periods of not less than one year all slaughter-houses coming into existence after such adoption. In London, slaughter-houses have been licensed since 1855. Private slaughter-houses are frequently situated at the rear of the shop in which the meat is sold. Each consists of a compartment in which the animals are killed, and in association with this are the pounds in which a few animals can be kept pending slaughter. These buildings are regulated by by-laws made under the Public Health Act by the several urban sanitary authorities. The by-laws usually provide for the floor to be made of jointless paving, to ensure that the earth shall not be fouled in the process of slaughtering; for the walls to be cemented to a certain height above the floor, to provide a surface which can be easily cleaned; for the doors to be of sufficient width to enable cattle to enter the slaughter-house without difficulty; and for the poundage to have floor-space sufficient for each animal. These by-laws also provide for water-supply to the slaughter-house for cleansing, and to the pounds for the use of the animals, for the periodical lime-whiting of the premises, and for the observance of care to prevent the blood escaping into the drains. Private slaughter-houses, especially those which were established without licence, are often in too close proximity to inhabited buildings. In towns in which by-laws are not strictly enforced they are often sources of nuisance. Private slaughter-houses are also objectionable on other grounds. They lead to the driving of cattle through the towns on the way to the slaughter-house, sometimes to the danger of the inhabitants, and they render impossible any systematic inspection of meat. It is in connexion with the increasing demand for such meat-inspection that the objections to private slaughter-houses are most manifested; and hence, in countries in which the law provides for the obligatory inspection of meat, private slaughter-houses are ceasing to exist, and public abattoirs are being substituted for them.

Private.

Public slaughter-houses are of great antiquity and owe their beginnings to Roman civilization. In 300 B.C. animals were slaughtered in the open air in the Forum in Rome. Later, to meet the convenience of butchers, a house on the river Tiber was given to them for the purposes of their trade. This house had been occupied by a Roman citizen named Macellus. The building appears to have retained his name, and hence the *macellum* of Livy's time subsequently erected in the Forum, which, *inter alia*, is believed to have contained rooms for the slaughter of animals. The rooms actually used for slaughter were *lanienæ*, from *laniare*, but the word *macellum* has been preserved in the Italian *macellare*, to slaughter, and in the German *metzgen* or *metzgeln*, and in the English *massacre*.

Public.

Public slaughter-houses existed in many large towns of Germany in mediæval times under the name of *Kuttelhöfe*; they were mostly situated on the rivers, which provided an ample supply of water, and afforded means for the removal of the blood which drained into them. Some of these Kuttelhöfe continued to exist within recent years. No law other than a town law governed their establishment and management. They were owned or controlled by the butchers' corporations or gilds, but all butchers were not members of the gilds; and this appears to have led to a ministerial order in Prussia in 1826, which made it inadmissible to require every butcher to slaughter in them. Shortly after the middle of the 19th century the prevalence of trichinosis compelled a return to the use of public slaughter-houses; and the enactment of laws in 1868 and 1881 in Prussia, and similar laws in other German states, empowered urban authorities to require that all animals killed in towns should be slaughtered in public slaughter-houses. (Schwarz, *Bau, Einrichtung und Betrieb öffentlicher Schlacht- und Viehhöfe.*)

In France, in the 15th and 16th centuries, numerous towns were provided with public slaughter-houses. It was required that they should be used by all persons killing animals the flesh of which was to be sold; but their position and the conditions they created were such as urgently to demand amelioration, and some effort was made in this direction in 1567. It was not, however, until the time of Napoleon I. that it was decided that the atrocious nuisance which these slaughter-houses created should be removed. By decrees passed in 1807 and 1810 public slaughter-houses were required to be provided in all large towns in France, the needs of Paris being determined by a Commission, which recommended the establishment of five abattoirs or public slaughter-houses. In 1838 the requirement that public slaughter-houses should be provided in large centres was extended to all towns in France, and it was further required that the slaughter-houses should be situated at a distance from dwelling-houses. In 1867 the large abattoir of La Villette was constructed to meet the needs of Paris, two of the five constructed under the decrees of Napoleon being closed. In 1898 the additional abattoir of Vaugirard was opened, and the remainder of the five were closed except Villejuif, which was restricted in its use to the slaughter of horses for human food.

For other countries the position may be more briefly stated. In Belgium public slaughter-houses have been provided in all the large and many of the small towns. In Switzerland there are public slaughter-houses in nearly all places having more than two thousand inhabitants. In Italy a law of 1890 required that public slaughter-houses should be erected in all communities of more than six thousand inhabitants. In Austria a law of 1850 required the provision of such places in all the large and medium-sized towns. In Norway and Sweden a law of 1892 required the provision of public slaughter-houses; but in Norway there is as yet only one, at Christiansund, and in Sweden there are none, though they are proposed at Stockholm, Gothenburg, and a few smaller towns. In Denmark there are public slaughter-houses in a few towns, including Copenhagen. In Russia, Spain, and Portugal some have existed for a number of years. It is in Germany, however, that the greatest progress has been made, and especially in Prussia, where Professor Ostertag, of Berlin, states they have "literally grown out of the ground" (*Handbuch der Fleischbeschau*); so much so that in 1897 there were 321 public slaughter-houses in the kingdom, 40 of which were provided in the period 1895–97.

In England the power to provide public slaughter-houses

was given by the Public Health Act, 1848, to the local authorities of cities, towns, boroughs, &c., to which the Act was applied by Order; and later, was given to all urban sanitary authorities by section 169 of the Public Health Act, 1875. These authorities have, however, suffered from the disadvantage that they have had no power to control the continuance of private slaughter-houses (except in so far as these were annually licensed), and they have therefore been unable to ensure that the public provision would be used by the butchers. In Ireland and Scotland much the same powers exist; but in Scotland, if the burgh commissioners provide a public slaughter-house, no other slaughter-house can be used. Some English local authorities have obtained in local Acts powers similar to those possessed by the burgh commissioners in Scotland. The need for still wider control is, however, manifest. Belfast may be cited as an illustration of a town in which a public slaughter-house has been provided, and in which there are no private slaughter-houses, but which receives a quantity of meat from private slaughter-houses erected beyond the boundaries of the city.

Regulations.

The outcome of these difficulties is that the power of local authorities to provide public slaughter-houses has been but sparingly used. There is no law requiring that meat shall be inspected before sale for human food, hence there is no obligation upon butchers to make use of public establishments for the slaughter of their cattle. This, indeed, is the position of some of the Continental slaughter-houses; but the increasing strictness of the laws as to meat-inspection, and especially in requiring that all animals shall be inspected at the time of slaughter, is making the use of public slaughter-houses obligatory. Such a law now exists in Belgium, where it has served as a model to other countries. An Imperial German law of 1900 extends to all parts of that country the same requirement, and enacts that "neat cattle, swine, sheep, goats, horses, and dogs, the meat of which is intended to be used for food for man, shall be subjected to an official inspection both before and after slaughter." Antecedent to that year it was in force in southern Germany, in Brunswick, and Saxony, but only in some parts of northern, western, and central Germany. A similar law exists in Norway and Sweden, but, as already stated, provision of public slaughter-houses is still wanting; in Austria-Hungary there is a similar requirement, but Ostertag states that the administration is lacking in uniformity; in Italy, he writes, the regulation of meat-inspection having been left to provincial authorities, thorough reform is impossible. In the British colonies advance is being made. The Meat Supervision Act of Victoria empowers the Board of Health to make regulations for ensuring the wholesomeness of meat supplies. Regulations have been made for Melbourne. Cattle are killed in public slaughter-houses and the carcases are stamped, thus showing in which slaughter-house they have been killed.

Construction.

The planning and construction of public slaughter-houses have been the subject of excellent treatises by German writers, among whom may be mentioned Dr Oscar Schwarz, of Stolp, and the late Herr Osthoff, city architect, Berlin, to whose works the author of this article is largely indebted for information. After inspection of the public slaughter-houses in England and in a number of Continental cities, the writer considers that those of Germany are most deserving of description.

The slaughter-house should be situated outside the town, or so placed as to be isolated, and approached by wide roads, so that if cattle are driven through them there should not be interference with the traffic. If possible, the slaughter-house should be connected with the railway system by a branch line, with a platform which has an impervious surface capable of being readily cleansed and disinfected. The most convenient shape of the site is a rectangle or square, having one side abutting on the principal road and another side bounded by the railway. A cattle-market is usually provided in connexion with the slaughter-house, and the position should be such that cattle brought by train can be taken immediately into the cattle-market and from the market or the railway to the slaughter-house. The cattle-market should be entirely separate from the slaughter-house area. Osthoff states (*Schlachthöfe für kleine und mittelgrosse Städte*) that the area of the slaughter-house should be as follows :—

		Sq. Metres.
Towns of 5,000– 7,000 inhabitants	.	0·40 per inhabitant.
,, 7,000–10,000 ,,	.	0·35 ,, ,,
,, 10,000–50,000 ,,	.	0·30 ,, ,,
,, over 50,000 ,,	.	0·25 ,, ,,

It is of course assumed that the population derives the whole of its meat-supply from this source.

The parts required, according to Dr Oscar Schwarz, are: (1) an administrative block; (2) a slaughtering-hall, with a special room for scalding swine; (3) cattle lairs; (4) room for scalding and cleansing tripe and intestines; (5) an engine-house; (6) separate slaughtering-room, with lairs for animals suffering from, or suspected to be suffering from, contagious disease.

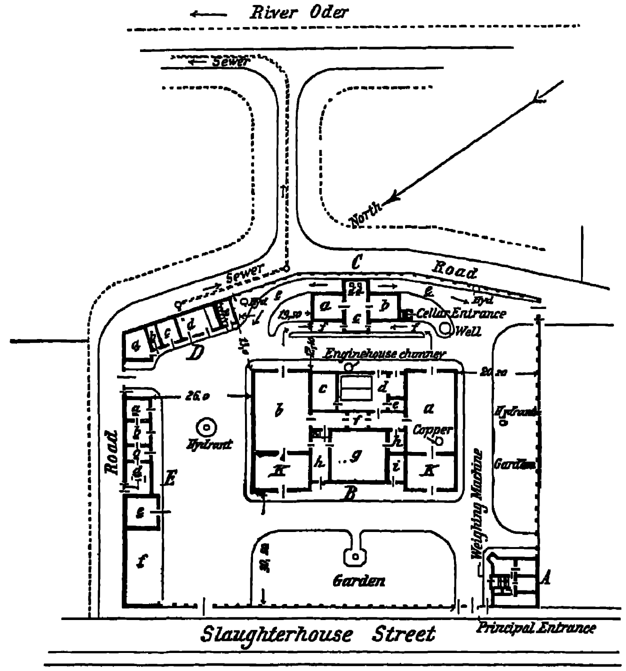
In small towns the slaughtering-hall and room for cleansing intestines may, to save cost of construction, be under the same roof. A necessary adjunct is a cold chamber, to which carcases can be removed from the slaughtering-hall. The actual slaughtering compartment has been built on two plans—one, providing a separate slaughtering-room for each butcher; the other, a common slaughtering-hall. The latter is greatly to be preferred, inasmuch as it is the only arrangement which gives adequate opportunity for inspection by the officials whose duty it is to examine the meat. The slaughter-house in Berlin was constructed on the separate-room system; but the writer was informed, when visiting it a few years ago, that it was intended to reconstruct it, on account of the difficulties of inspection of which it was the cause. During recent years in Germany the practice has been to construct slaughter-houses with common halls. The part occupied by each butcher at the time of slaughtering is, however, sufficiently distinguishable, and at Hamburg the position of the hooks hanging from above divides the hall into separate areas, each of which has an entrance from without. Schwarz gives the following as the most convenient arrangement of the buildings :—The administrative building (with the house of the superintendent) at the entrance, so that from it the entrance and whole place can be seen. In the vicinity should be a weighing-machine for cattle. The centre of the area is occupied by the slaughtering-halls, and the lairs belonging to them only separated from them by a road or passage way. The manure-house and tripe-house must be easily accessible from all the slaughtering-halls, but not in direct communication with them, or smell from them may enter the hall.

The manure-house must abut upon a road, to enable its contents to be removed without passing through the premises. Next to the tripe and pig-scalding houses is the engine-house. The building for diseased animals, with the slaughter-house for them, must be isolated from all other buildings. All buildings should be so arranged that they may be capable of extension as the population of the town increases. By the provision of grass plots and trees every effort should be made to relieve the premises of the dreary appearance they will otherwise present.

Cold chambers, although not included among the absolute essentials for small slaughter-houses, are an almost necessary adjunct, for they serve for the preservation of the meat after slaughter, and are indeed absolutely necessary when the slaughter-house is of large size. The cold chamber should be situated opposite the slaughtering-halls, so that carcases can be conveyed by overhead carriers directly from those halls to it. Within the cold chamber are separate compartments or cages of different sizes, rented by butchers, who are thus able to preserve their meat and draw upon their supply as their business may require. The cold chamber is therefore a great convenience to the butchers, and is a source of profit to the authority owning the slaughter-house. A frequent adjunct to large German slaughter-houses is the "Freibank," at which is sold at low price cooked meat of quality which renders it unfit to be sold under ordinary conditions.

Much depends upon the design and details of construction of the several component parts of a public slaughter-house, upon the provision of adequate lighting and ventilation of the buildings, upon the construction of walls, floors, and fittings which are impermeable and can be readily cleansed, and upon the provision of an abundant water-supply. It is essential that the buildings should be well lighted, especially those which are used for the slaughtering operations, or for any detailed examination of meat which may be needed—such, for instance, as for trichinæ. The material generally used for the floor of the slaughtering-hall is cement or granolithic pavement, which must not present so smooth a surface as to be slippery. The floor must have an adequate fall, so that the washings may discharge into a system of drainage.

The plans of the public slaughter-house of Neusalz on the Oder and of Düsseldorf well illustrate the provision which is now made respectively for a small and for a large town. The writer is indebted to Dr Schwarz for the plan and a description of the slaughter-house at Neusalz. It was completed in October 1899,



The figures give measurements in metres.

FIG. 1.—Plan of Public Slaughter-House at Neusalz on the Oder (1899).

and is erected on the Oder below the town, on land of an area of 8500 square metres. The building has been carefully planned by the town architect, Herr Brannaschk, so as to admit of increase within the next 10–20 years. Brickwork is used for the construction of the buildings, and the roofs are wood and cement. The walls of all the rooms except those of the administrative block are lined partly with polished stone, partly with cement, to a height of two metres above the floor. The floors consist of stone slabs set in cement (Fig. 1).

The administrative block (*A*) is situated at the entrance and is a three-storey building, containing an office, a room for examination of meat for trichinæ, and dwelling-rooms for the superintendent. In the central block (*B*) two slaughter-halls are provided (*a*) for swine and (*b*) for cattle and sheep. With these are associated (*c*) an engine-house, (*d*) a boiler and fuel room, (*e*) a workshop, (*f*) a passage communicating with the two slaughter-halls, (*g*) a cold chamber, (*h*) ante-rooms to the cold chamber, (*i*) dressing-rooms for assistants, and (*k*) stabling. The cold chamber has an area of 169 square metres and contains 28 cells of various sizes. In order to attain an even temperature of 2° C. to 4° C., air rendered cold by the ammonia process is conveyed to the room by channels. In the engine-house (*c*) are a 48-horse-power engine, the cooling machines, and the water-pump, which pumps water from a well into two cisterns situated in a water-tower over the passage between the two slaughter-halls. In the outbuilding (*C*) are (*a*) and (*b*), the gut-washing rooms for cattle and swine respectively, (*c*) an ante-room with (*d*) openings for manure to be thrown into carts. The road (*e*) slopes downwards, so as to enable a cart to be driven below the openings through which the manure is discharged. In the outbuilding (*D*) are (*a*) a horse slaughtering-room, (*b*) a stable, (*c*) a bathroom, (*d*) a room in which the floor washings are treated chemically or by filtration before discharge into the river, and (*e*) a urinal. In the outbuilding (*E*) are (*a*) a stable for sick animals, (*b*) a slaughter-house for diseased animals, (*c*) a sterilizing-room for meat to be subsequently sold in (*d*) the "Freibank," (*e*) a stable for horses, and (*f*) a cart-shed. The slaughter-house is to be lighted with electric light. The cost of the buildings is about £19,000, and provides for a population of from 20,000 to 25,000 inhabitants.

The slaughter-house at Düsseldorf is on a more extensive scale.

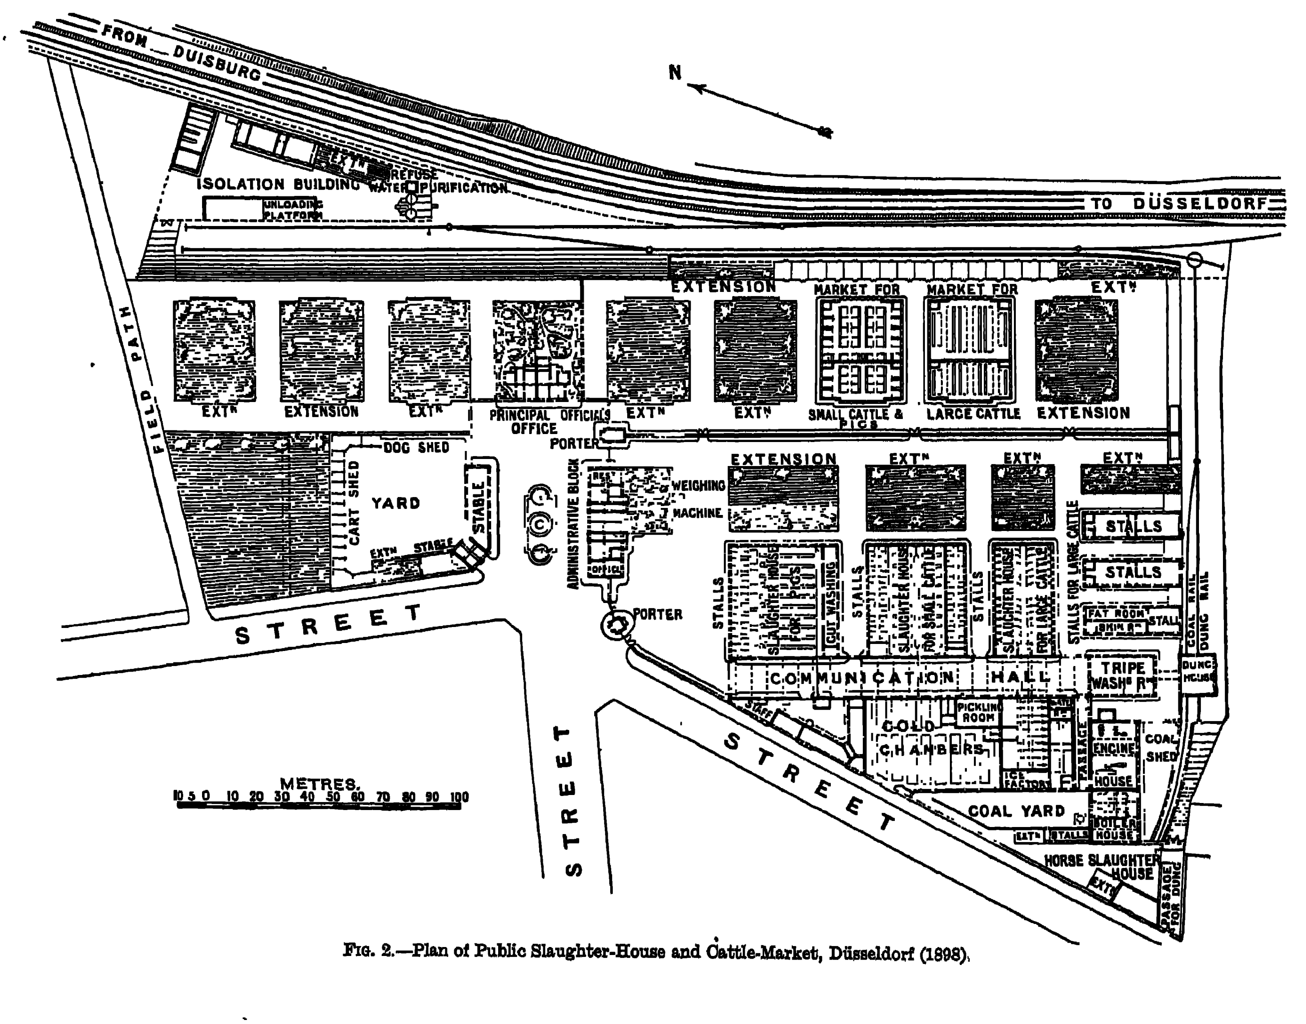


FIG. 2.—Plan of Public Slaughter-House and Cattle-Market, Düsseldorf (1898).

It was erected at an estimated cost of from £162,000 to £175,000, and covers an area of about 23·2 acres. Provision is made for each department to be practically doubled in size. It is unnecessary to describe it in any detail, but it may be noted that it has a market associated with it, and that separate slaughter-halls are provided for large cattle, for small cattle (sheep and calves), and for swine (Fig. 2). The population of Dusseldorf was 212,949 in 1900.

The average cost of slaughter-houses in Germany is given by Osthoff, of Berlin (*Handbuch der Hygiene*), as 7 to 8 marks per inhabitant if no cold chamber is provided, and from 10 to 12 marks per inhabitant if there is a cold chamber, or, in more detail, as follows :—

Number of Inhabitants.	Cost of Slaughter-house per Inhabitant, in Marks.	
	Without Cold Chamber.	With Cold Chamber.
5,000– 6,000 . .	8	12
6,000– 8,000 . .	7	10
8,000–15,000 . .	6	9
15,000–20,000 . .	7	10
Over 20,000 . .	8	10

Slaughter-houses in Germany pay their own expenses, the fees received for the use of the slaughter-house, and for examination of meat and stamping after examination, providing a sufficient sum for this purpose. The fees vary in different places. From the works of Osthoff and Schwarz it would appear that these fees average about one pfennig per kilogramme of the living animal, or about half a farthing per ℔ of meat.

In Chicago and certain other western American cities large numbers of cattle are slaughtered and the meat prepared for transmission to all parts of the world. The important feature of these slaughter-houses is their adaptation for rapidly dealing with the animals which they receive. At the Chicago slaughter-houses the cattle to be slaughtered are driven up a winding viaduct, by which, in certain of the houses, they eventually reach the roof. Each animal now passes into a narrow pen, where it is at once stunned by a blow on the head. It then falls through a trap-door in the pen into an immense slaughtering-room, where the hind legs are secured, and the animal hoisted by a wire rope suspended from a trolley-line. A knife is then plunged into its throat and the carcase made to travel along the line. The carcase is next lowered to the floor, the hide taken off, the head and feet cut off and the internal parts removed. The carcase again travels along the trolley-line to a place where it is divided into halves, which then, after washing, travel to the refrigeration-room, being trimmed while on the way. The extent of the business may be judged by the fact that over 400 cattle are killed per hour in the slaughtering-room. The cooling-rooms are so large that 13,000 halves of beef hang there at one time. The method of dealing with sheep is very similar. The animals are driven into narrow alleys, then into the slaughter-room, where their throats are cut. They next travel along a route where their skins and the internal organs are removed, and finally pass into the cooling-rooms. Swine are raised in the slaughter-room on to the trolley-line by a chain attached to the animals' feet and to a solid disc or wheel, which in revolving carries them until a mechanical contrivance throws the chain upon the trolley-line where a knife is plunged into their throat. In its subsequent passage the carcase is scalded, scraped by a machine through which it passes, later decapitated, the internal parts removed, and the interior washed. The carcase then travels to the cooling-room.

The use of public slaughter-houses has not been found to affect the price of meat, although one of the numerous arguments used by butchers against being required to slaughter in public slaughter-houses was that they would have this effect. The increasing recognition in European countries of the need for inspection, at the time of slaughter, of the flesh of all cattle intended to supply food for man, the necessity for the provision of public slaughter-houses to make such inspection practicable, the convenience which these slaughter-houses afford to those engaged in the business of butcher, combine to ensure that, at any rate in all populous places, they will in time entirely supersede private slaughter-houses, which offer none of these advantages.

No doubt the provision of public slaughter-houses will continue to be opposed by the butchers' trade so long as private slaughter-houses are permitted, and, as already stated, local authorities in England are discouraged from making public provision by their inability to prevent the continuance of the use of all existing private slaughter-houses. Probably the extension to English local authorities of the power which the law of Scotland gives to the commissioners of Scottish burghs of closing private slaughter-houses when a public slaughter-house has been provided, would facilitate the much-needed substitution of public for private slaughter-houses. (S. F. M.)

Sligo, a maritime county of Ireland, province of Connaught.

Population.—The area of the administrative county in 1900 was 442,205 acres, of which 73,364 were tillage, 236,818 pasture, 82 fallow, 7123 plantation, 35,716 turf bog, 6517 marsh, 65,382 barren mountain, and 17,203 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, comprises the whole of the old judicial county except 3 electoral divisions now added to Mayo. The population in 1881 was 111,578; in 1891, 98,013; and in 1901, 84,022, of whom 41,760 were males and 42,262 females, divided as follows among the different religions: Roman Catholics 76,194, Protestant Episcopalians 6362, Presbyterians 648, Methodists 529, and other denominations 289. The decrease of population between 1881 and 1891 was 12·16 per cent., and between 1891 and 1901, 11 per cent. The average number of persons to an acre in 1891 was ·21, and of the total population, 86,545 persons inhabited the rural districts, being an average of 178 persons to each square mile under crops and pasture. The following table gives the degree of education in 1891 :—

	Males.	Females.	Total.	Percentage.			
				R.C.	Pr. Ep.	Presb.	Meth.
Read and write .	29,729	29,387	59,116	64·7	88·8	92·5	94·4
Read only	4,458	4,989	9,447	11·2	5·5	3·6	2·9
Illiterate	9,615	10,131	19,746	24·1	5·7	3·9	2·7

The percentage of illiterates among Roman Catholics in 1881 was 33·3. In 1891 there were 8 superior schools, with 296 pupils (Roman Catholics 189 and Protestants 107), and 226 primary schools, with 15,061 pupils (Roman Catholics 13,629 and Protestants 1432). The number of pupils on the rolls of the national schools on 31st December 1900 was 15,776, of whom 14,407 were Roman Catholics and 1369 Protestants. The following table gives the number of births, deaths, and marriages in various years :—

Year.	Births.	Deaths.	Marriages.
1881 . .	1999	1157	281
1891 . .	2011	1394	316
1900 . .	689	350	286

In 1900 the birth-rate per 1000 was 20·1 and the death-rate 16·1; the rate of illegitimacy was ·4 per cent. of the total births. The total number of emigrants who left the county between 1st May 1851 and 31st December 1900 was 74,658, of whom 35,413 were males and 39,245 females. The only town of any importance in the county is Sligo, which in 1891 had a population of 10,274, and in 1901 of 10,862.

Administration.—The county is divided into two parliamentary divisions, North and South, the number of registered electors in 1901 being respectively 8281 and 7570. The rateable value in 1900 was £213,457. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises 1 urban and 4 rural sanitary districts.

Agriculture.—The following tables show the acreage under crops, including meadow and clover, and the amount

of live stock in 1881, 1891, 1895, and 1900. The figures for 1900 are for the new administrative county:—

Year.	Wheat.	Oats.	Barley, Rye, Beans, &c.	Potatoes.	Turnips.	Other Green Crops.	Meadow and Clover.	Total.
1881	324	25,907	1091	22,485	3362	1736	34,959	89,864
1891	387	17,892	726	16,382	2959	2225	33,534	74,105
1895	290	17,753	747	16,557	3184	2041	38,702	79,274
1900	288	14,388	697	14,658	2492	2859	37,982	73,364

For 1900 the total value of the cereal and other crops was estimated at £488,295. The number of acres under pasture in 1881 was 225,099; in 1891, 240,301; and in 1900, 236,818.

Year.	Horses and Mules.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1881	8638	7806	89,238	59,837	18,934	4074	345,071
1891	9024	8835	93,376	88,228	24,748	6980	359,244
1895	9438	9045	94,460	75,474	27,441	6393	402,447
1900	7720	9727	96,351	72,572	29,042	6785	434,844

The number of milch cows in 1891 was 31,298, and in 1900, 31,374. It is estimated that the total value of cattle, sheep, and pigs for 1900 was £1,383,087. In 1900 the number of holdings not exceeding 1 acre was 824; between 1 and 5, 1381; between 5 and 15, 5589; between 15 and 30, 4337; between 30 and 50, 1597; between 50 and 100, 781; between 100 and 200, 298; between 200 and 500, 129; and above 500, 35—total, 14,971. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1901, was 683, amounting to £128,957. The number of loans for agricultural improvements sanctioned under sec. 31 of the Land Act, 1881, between 1882 and 1901 was 512, and the amount issued £34,633. The total amount issued on loan for all classes of works under the Land Improvement Acts from the commencement of operations in 1847 to 31st March 1901 was £139,932.

Fisheries.—In 1900, 159 persons were employed in the salmon fishery district of Sligo.

Sligo, a maritime town, capital of the above county, on the river Garavogue, 137 miles north-west of Dublin by rail. Under the Local Government (Ireland) Act, 1898, it retains its mayor and corporation, but has practically the status of an urban district council. In all 740 vessels, of 107,060 tons, entered in 1900, and 607, of 66,012 tons, cleared. Population (1891), 10,274; (1901), 10,862.

Sliven, or Slivno, the chief town of a department in Eastern Rumelia, Bulgaria, near an important defile of the Balkans called the Iron Gate, 100 miles east-north-east of Philippopolis. Its black wine is still famous. Thoroughly modern machinery has been introduced into the Government factory, which employs about 300 hands; and the cloth manufacture for the army equals that of any other European country. Bulgarian home-spuns ("shayak") are also manufactured, and there is a small trade in silk. The general trade in staple articles is large. There is an important higher class school, with 40 professors and attended by about 800 pupils. Population (1892), 23,210; (1900), 24,542, of whom nine-tenths are Bulgarians.

Slobodskoi, a district town of Russia, in the government and 20 miles to the north-west of Vyatka, on the river Vyatka. It was founded in 1546 and is now a growing town. It has distilleries, match and glue works, tanneries and breweries, and carries on a brisk trade, chiefly in oats, flax, linseed, and wooden ware. Population (1897), 10,052.

Slocum, Henry Warner (1827–1894), American soldier, was born in Onondaga county, New York, 24th September 1827, and graduated at the United States Military Academy in 1852. He resigned in 1856 to practise law at Syracuse, N.Y. When the Civil War broke out he became a colonel (May 1861) of the 27th New York volunteers. He fought through the Virginia campaigns (1861–63), as brigadier and then as major-general of volunteers. In the west, in 1864, he occupied Atlanta in September, and led the left wing through Sherman's march of invasion. He resigned from the army, September 1865, resumed professional practice at Brooklyn, and was chosen to Congress, 1868, serving three terms. He died at Brooklyn 14th April 1894.

Slough, a market-town in the Wycombe parliamentary division of Buckinghamshire, England, 18 miles west of London by rail, and 2 miles north of Windsor. The Leopold Institute is a memorial of the Duke of Albany. The town has been formed into a civil parish (an urban district), comprising the parish of Upton-cum-Chalvey and part of Stoke Poges. Area, 1639 acres. Population (1891), 8713; (1901), 11,461.

Smaldeel. See Orange River Colony.

Small Arms.—British and Foreign.—For a table of the rifles in use up to 1880, a short history of the development of firearms, and a general description of manufacture (the last being much the same at the present time), the reader is referred to the article "Gunmaking" in vol. xi. of the *Ency. Brit.*, 9th edition. The rifle, however, now in the hands of the soldier, whether British or foreign, differs very greatly from that of 1880, being superior to the latter in velocity, range, penetration, and accuracy; while the cartridges, with which it is loaded, are charged with a smokeless explosive and contained in a magazine from which they are automatically fed, ready to be at once pushed home into the breech.

Repeating rifles.

The repeating or magazine system, now universally adopted, may be said to date back to about 1840, when the first repeating rifle was brought out by Colt in America. The Henry, Spencer, and Winchester (all American) systems followed, the last-named still holding the field, and being perhaps the proximate cause of the general adoption of the magazine in all military rifles; for in the Russo-Turkish war of 1877–78 some of the Turkish troops were armed with this rifle, and the rapidity of fire obtainable with it brought the repeating system prominently forward, with the result that by 1886 all the important Powers, with the exception of the United States, Great Britain, and Russia, had armed their troops with magazine rifles.

These earlier patterns were all of large calibre (that is, not less than ·45 inch), being frequently conversions of the single-loaders previously used to avoid the heavy outlay on a completely new armament; but the advantages of a smaller calibre were soon discovered, the earliest experiments in this direction having apparently been originated by Major Rubin in Switzerland in 1883. The smaller calibre brings with it certain distinct advantages, viz., a lighter bullet and smaller charge, and as a consequence a lighter cartridge; and a higher velocity without undue recoil, since the recoil varies directly as the weight of the bullet and charge. As a consequence of the lighter bullet, the soldier can carry many more

cartridges than formerly, while the absence of recoil combined with a flat trajectory enables him to shoot with far more accuracy and greater prospect of striking his foe. Owing to the trajectory of the British ·303-inch magazine rifle, when firing at an object 500 yards distant, never rising more than $4\frac{1}{2}$ feet above the direct line of sight, the British soldier is taught always to aim at the feet of his enemy when once he has come within that range, and not to alter his sights as the range decreases, since, if his aim be moderately correct, though he will hit the objective higher and higher up, he will still hit it somewhere. At a range of 350 yards the bayonet is usually fixed, and this always tends to cause low shooting at a time when excitement is apt to make men shoot high. The 500-yards sight is therefore termed the "fixed sight."[1]

Small calibre: advantages.

On the other hand, the small calibre has some very definite disadvantages. In order to get the requisite weight, a small-calibre bullet must be much longer proportionately than the larger-calibre bullet. The ·303-inch bullet, for instance, weighing only 215 grains, is 1·25 inches long, while the Martini-Henry bullet, ·45 inch in diameter and weighing 480 grains, is only 1·27 inches in length; and this greater length, as compared to diameter, necessitates a much sharper pitch of rifling in order to revolve the bullet sufficiently rapidly to keep it point first. The pitch in the British ·303 rifle is one turn in 10 inches, and in the Martini-Henry one turn in 22 inches.

Its disadvantages.

Bullets of the hardest lead when fired from barrels with this high-pitched rifling were found to "strip," that is, they were forced through the barrel without rotation being impressed on them, their surfaces being torn off. To remedy this, the lead bullet must be encased in an envelope of harder material (the envelope of the British bullet is made of cupro-nickel), and this hard envelope produces some exceedingly important effects. The enveloped bullet has a much higher penetrative power than one of lead only; but on the other hand there is no doubt that, unless it should happen to strike a large bone (more especially if it should do so when it first enters the body, as it then drives the splinters forwards), it does not inflict nearly such severe wounds, nor has it such a stunning effect as the old lead bullet. The cause is obvious: it cuts a small clean hole and does not deform. This fact is of great military importance, especially in warfare with savages, in which the chief danger is usually a rush of enormous numbers at close quarters.

A minor disadvantage arises from the fact that the hard envelope wears away the rifling of the barrel more rapidly than lead does; the latest pattern, British rifle, will, however, fire at least 8000 rounds before being sufficiently worn materially to impair its accuracy, and in ordinary circumstances any rifle will become unserviceable from other causes long before that number is fired. The advantages, however, of the small calibre have been judged to outweigh the disadvantages, and it has been universally adopted. (See the table at the end of this section.)

Smokeless powder.

As already stated, a smokeless explosive has been adopted universally. It is the natural concomitant of the magazine system, and without it the advantages of the latter would be enormously reduced, since in the case of a rapid fire with the old smoky powders the firer is quickly enveloped in a cloud of smoke, which, besides betraying his position to his enemy, prevents him from seeing to take aim. France was the first to recognize and take action in this matter, and in 1886 armed her troops with a small-bore magazine rifle firing a smokeless propellant.

Most nations arm their cavalry with carbines. The carbine generally has the same breech mechanism and fires the same cartridge as the rifle used by the infantry, but is much shorter and is rarely fitted for a bayonet. Italy is an exception, her carbine having a bayonet which folds under the carbine on a hinge. The carbine usually has a wooden hand-guard extending nearly to the muzzle, to enable it to be grasped, when heated by rapid firing, in almost any position, so that the trooper may not be hampered in hurried mounting. The bolt knob is also made to fold down more closely, to be convenient for carrying slung on the back, or in the leather sheath or carbine "bucket" on the saddle. (See Figs. 12 and 16.)

Automatic rifles.

Although no nation has yet armed her forces with an automatic rifle—that is, a rifle in which the recoil, or a portion of the gases of explosion, is used to do the work of opening and closing the breech which is now done by hand—it is not because such weapons have not been made to work practically. There are already some rifles, and more pistols, of this class before the world, notably the Maxim, Woodgate, Mannlicher, Bergmann, and Mauser. A perusal of the article on MACHINE GUNS in this work will show the principles on which automatic mechanism can be provided. So far the recoiling barrel has been mainly utilized. Of course, automatic rifles could not of necessity be so simple or so free from liability to damage as the existing rifles, and they would also probably be slightly heavier. Complication is, however, merely comparative, and many weapons of war which, with reasonable care, are now found to be perfectly serviceable for the roughest campaigning, would have been scouted as wholly unsuitable in the 'seventies. The gain in rapidity of fire with an automatic rifle should be out of all proportion to that due to merely getting rid of the time taken in working the bolt; for, with the slight recoil given by the light bullet of the modern rifle (especially if that recoil be largely absorbed in working the mechanism), it would appear possible with an automatic weapon to keep the eye continually on the sights and to maintain the aim, the recovery of aim being at present one of the great factors in the rate of fire, if accuracy be combined with rapidity. On the other hand, the potential waste of ammunition would be equally increased, and the rifles would be considerably more costly. Looking, however, to the past, it certainly appears more than probable that the adoption by any one great Power of the automatic system would force it on all.

British Rifles.—The Lee-Metford or Lee-Enfield magazine rifles or carbines, with which the British army and navy are armed, have the Lee breech and magazine mechanism and the Metford or Enfield system of rifling. The latter has superseded the former, as it stands the wear caused by the enveloped bullet more successfully. Compare Figs. 1 and 2. The various patterns (see General Table) differ only in details; the principle of the mechanism is the same in all, and they take the same cartridge and bayonet.

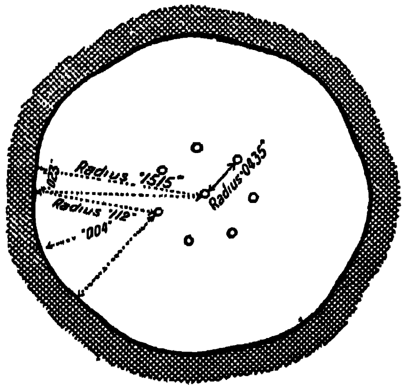

Fig. 1.

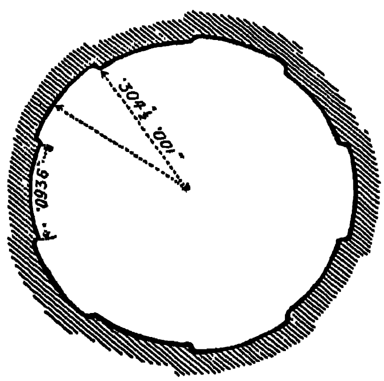

Fig. 2.

The breech (see Figs. 3 to 9) is closed by a bolt I, with bolt-head O, which slides in a "bolt-way" cut for it in the body B, much as does an ordinary door bolt. When pushed home, and the bolt knob turned down, the bolt is locked, the bolt-head O

[1] This applies especially when accurate range-finding is practically impossible. Of course there are occasions when alteration of sights should be made for short ranges.

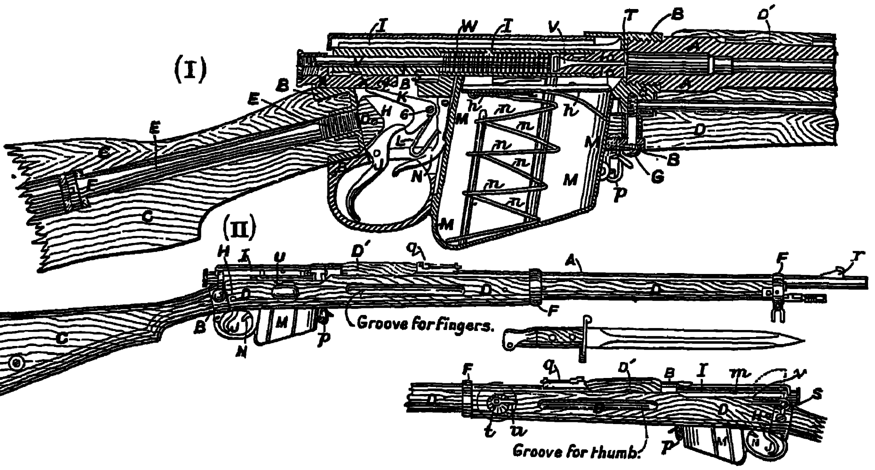

Fig. 3.

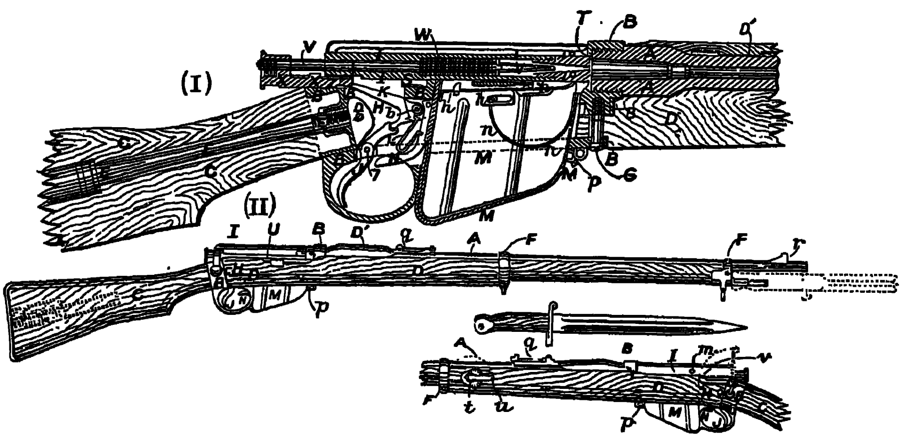

Fig. 4.

abutting against the base of the cartridge. Movement backwards is prevented by the rib P being brought in front of the lug Q on the body B, and a projection R (Fig. 6) being turned into the groove S in the interior of the bolt-way. Upward movement is prevented by the bolt being partially enveloped by the bolt-way and the bolt-head fitting into the recess T just in rear of the breech. The bolt contains the striker V and main spring W. The former is attached to the cocking-piece X. Supposing the bolt fully withdrawn (see Fig. 6) it is clear that as it is pushed forward the toe Y of the cocking-piece X will encounter the nose Z of the trigger sear K; and if the bolt be then pushed home, the spring W will be compressed, owing to the cocking-piece and striker being held back. If now the trigger J be pulled, the nose of sear K is depressed and the striker flies forward and fires the cartridge. When released, the striker can be cocked by pulling out the cocking-piece by hand. If placed on half-cock, the shape of the half-cock notch Z′ causes the sear nose to be locked and the trigger cannot be pulled. In the later patterns a safety catch is provided (see Fig. 10). This is a prolongation (d) of the cocking-piece X carrying a thumb-piece (f). When the latter is turned up, a half-round axis-pin (e) can be turned into either of the semicircular slots (b) or (c) on a prolongation (a) of the bolt I, and the cocking-piece is then locked to the bolt.

The magazine M is a detachable sheet steel box (see Figs. 3, 4, and 9). It is provided with a platform (h) pushed upwards by a spring (n). On this platform the cartridges (ten, in two parallel but overlapping columns of five, in the later patterns) rest, the spring (n) being compressed as the magazine is filled. The tops of the side walls of the magazine are bent inwards, and, while permitting the magazine to be filled with cartridges one by one, will not allow them to escape until pushed forward about an inch. Pivoted in the body is the "cut-off" or lid (g) (see Figs. 7 and 8). When this is closed, the cartridges in the magazine are kept down clear of the bolt-way.

When using the rifle as a single-loader the cut-off is closed, the bolt is withdrawn, and a cartridge placed on the cut-off and partially in the breech. It is then pushed home by the bolt, and as this is done the claw (k) of the extractor rides up over, and hooks on to, the cartridge's rim; consequently, when the bolt is withdrawn, the cartridge (fired or unfired) is pulled out with it, and is ejected, its base, on the side opposite to that held by the extractor claw, striking against the ejector screw (m) and being thus canted to the right and thrown clear of the rifle (see Fig. 7). It should be noted that, as the bolt is turned for opening, the projection R working in the cam groove S causes the bolt to recede very slightly and to draw back the cartridge correspondingly. Owing to leverage, this first shift can be effected with considerable power in case a cartridge should stick. Once shifted the cartridge case can be readily extracted, as it is coned. This action is termed "primary extraction."

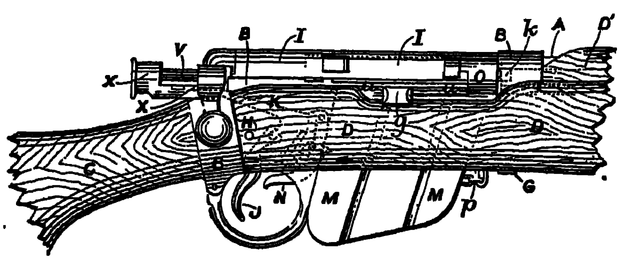

Fig. 5.

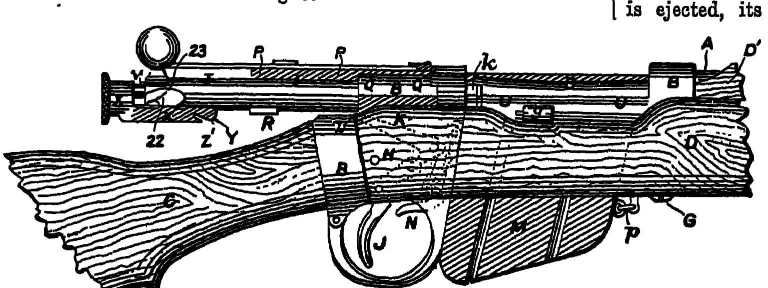

Fig. 6.

The forward part of the cocking-piece X has a stud X′, which, in combination with the cam groove 22 and projection 23 on the under side of the bolt I, performs the function of preventing the rifle from being fired when the breech is not properly closed, and also causes a slight withdrawal of the point of the striker when the bolt is opened. It should be observed in this connexion that the cocking-piece X, though it can move longitudinally, cannot *turn* with the bolt.

To load from the magazine (see Figs. 8 and 9) the cut-off (g) is opened. The cartridges immediately rise and a portion of the base of the top cartridge (o1) can be engaged by the bolt-head O and pushed into the breech. Immediately

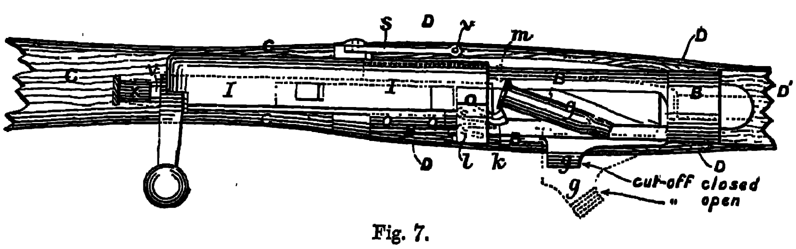

Fig. 7.

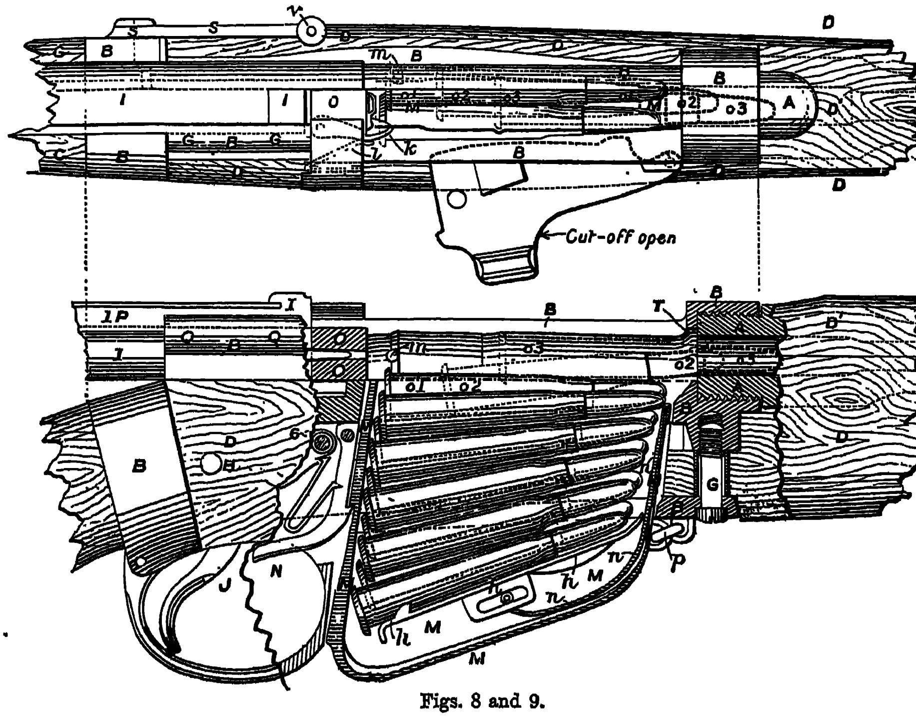
this cartridge is fired, extracted, and ejected, another cartridge rises in front of the bolt ready to be pushed home; (*o*1) (*o*2) (*o*3) represent the different positions of the cartridge, (*o*1), as it is pushed from the magazine into the breech.

The bolt, extractor, ejector, safety, and magazine actions, described above, are much the same in principle in all magazine rifles with box magazines, but the diversity of detail is considerable. The principal feature in which the British rifle differs from others is in the method of filling the magazine. The underlying principle of the British magazine is that the rifle shall be normally used as a single-loader, and exceptionally as a magazine weapon, the store of cartridges in the magazine being retained intact for emergencies. Continental Powers, on the other hand, with a few exceptions, have adopted rifles without cut-off, and always load from the magazine. To fill the latter rapidly the cartridges are carried packed in bundles of from three to six, in sheet metal or cardboard receptacles. These receptacles are of two kinds, "clips" or "chargers."

The clip, employed in the Mannlicher system, is used with a magazine with parallel walls, being held down in the magazine against the pressure of the magazine platform spring by means of a spring catch. It has its sides turned over at top and bottom to retain the cartridges until pushed forward some distance by the bolt; but openings are left through which the magazine platform spring can act on the cartridges, and also to permit the clip to fall out past the platform spring, through a hole in the bottom of the magazine, when empty (see Figs. 13 and 15). The charger, used in the Mauser system, does not enter the magazine, but is placed



Figs. 8 and 9.

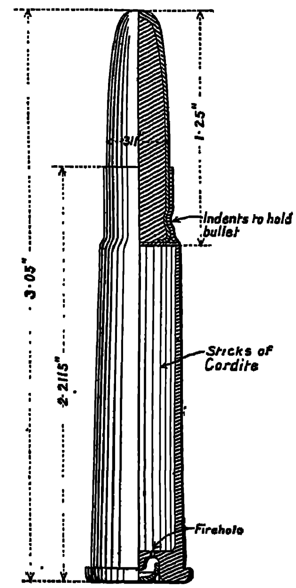


Fig. 11.

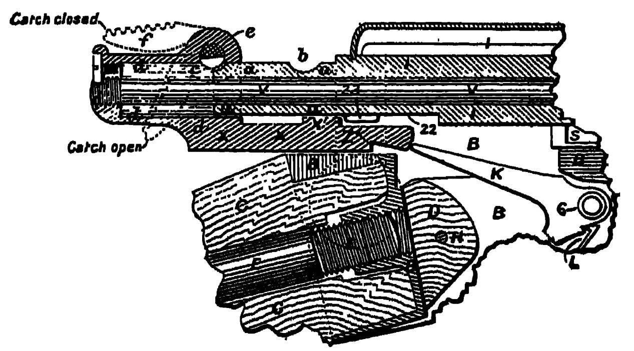

Fig. 10.

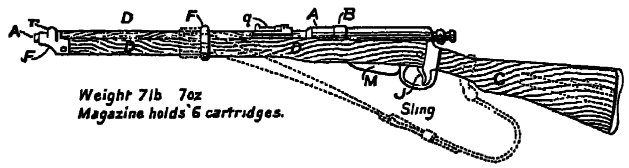

Fig. 12.

over the top of the magazine, and all the cartridges in it pushed by *one* motion into the magazine. A magazine with overlapping walls allowing entry but not exit (except, of course, by the push of the bolt) is necessary with a charger. The British rifle could be adapted easily for loading by charger, if this were considered desirable.

Besides the vertical box magazine systems there are the horizontal box and tube systems. The former, the Krag-Jörgensen, is described under the section *United States* below. The latter, the oldest European magazine system and termed the Kropatschek, consists of a tube under the fore end in which the cartridges lie base to point, being pushed backwards to the breech by means of a long spiral spring. By an extremely neat though intricate mechanism the cartridges are placed one by one on a pivoted carrier (*h*) and presented in front of the bolt (see Figs. 18 and 19). It is highly improbable that France would again adopt the tube system in any new pattern of rifle, as it has the following objections when compared with the box system, whether vertical or horizontal:—It is exceedingly cumbrous for an equal number of cartridges; its feed and cut-off mechanism is very complicated; the balance of the rifle is much more altered as the magazine empties; the placing of the cartridges base to point, even when the bullet has a flat point, is not unattended with danger, especially when the magazine is full and the spiral spring strongly compressed; lastly, loading by any form of charger is practically impossible.

As regards the foreign rifles and cartridges shown in Figs. 13 to 19, their principal features are as follows:—

Austria-Hungary.—Both the 1890 and 1895 patterns have "straight-pull" bolts; that is, bolts which are not turned for locking. The bolts are in two parts which "telescope" into each other. In the 1890 pattern (see Fig. 13) when the bolt I is home against the cartridge and the "lever cylinder" I′, which carries the bolt knob, is further pushed forward, the hinged block R is caused to drop in front of the resistance piece Q, and so locks the bolt I against the cartridge. In the 1895 pattern (see Fig. 14) the final pushing forward of the lever cylinder causes the head of the bolt I to turn and projections on its head to lock into recesses SS just in rear of the breech. The turning is due to helical feathers (20) on the inside of the lever cylinder I′ working in grooves in the rear of the bolt I. The trigger mechanism in the 1890 pattern is the "double pull," much used in Continental arms. It will be seen from the figure that as the trigger is pulled the bearing is taken first at (8) and then at (9). This gives, owing to the change of leverage, power at the commencement and rapidity at the end of the pull; and by this means a heavy pull, to give

† The Mark I.* only differs from Mark I. in not being fitted with a clearing rod.
§ A charger can be used with the Krag-Jörgensen system if desired.
‖ Increasing twist from 1 turn in 19¾ inches at breech to 1 turn in 8·25 inches at muzzle.
** Germany is re-arming with a new rifle (Pattern 1898) with charger loading on the latest Mauser system. This rifle has no barrel casing (see text); but it has the same calibre and muzzle velocity and takes the same cartridge as the 1888 pattern.
§§ Japan is re-arming with a new rifle (pattern 1900) on the Mauser system. It has a calibre of ·256 inches, O.V. of 2286 f.s., and is about 1 lb lighter than the 1893 pattern.
‡ The United States have decided to re-arm the navy with a rifle of the same calibre as that used by the army.

safety against accidental discharge, is combined with a light pull at the moment of firing. The loading by clip has been explained.

Germany.—The rifle (see Fig. 15) has a turning bolt, projections on the bolt-head being turned into recesses SS in rear of the breech to lock the bolt. The special feature of this rifle is the steel barrel casing A′, which permits the use of a lighter and cheaper barrel, since it protects the latter; it allows free expansion of the barrel when heated, facilitates equal radiation of the heat into the air-space between the barrel and casing, and mitigates the evil effects of warping of the stock. There are, however, also very obvious objections to this casing, and it has only been adopted by Germany, Belgium, and Denmark. The cartridge used is rimless (see Fig. 17). There is a slight advantage in this class of cartridge in that there is no necessity to make any provision for preventing the rim of a cartridge getting in front of the cartridge next above it. A reference to Fig. 9 will show that a jam would result if this occurred. The German clip can therefore be put into the rifle either way up, the Austrian clip in only one way.

France.—This rifle (see Figs. 18 and 19) calls for no special remark. Its bolt is very similar to that of the British rifle, and its special peculiarity—its tube magazine—has already been discussed.

The rate of fire with magazine rifles, if we merely reckon the time to load and *discharge* the rifle, may be taken roughly at ten rounds in about 15 to 20 seconds. This rate is, however, valueless for practical purposes. The only rate worth considering is that of *aimed* fire. This is roughly about three times that of a single-loader, and at a very easy target ten rounds might be fired with fairly good results in from 30 to 40 seconds.

(H. W. B.)

UNITED STATES.

Rifles.—The United States magazine rifle, calibre ·30, model 1892, adopted after exhaustive competitive tests and improved in the models 1896 and 1898, is upon the Krag-Jörgensen system. The fixed magazine for five cartridges is placed horizontally under, and also to the left side of, the receiver. The normal use of the rifle is as a single-loader, a cut-off allowing the cartridges in the magazine to be held in reserve. The main advantages claimed for this reserve magazine rifle over a clip-loading repeating rifle, designed only for magazine fire, are its convenient use as a single-loader, the full reserve of ammunition always instantly available for the supreme moment in an action, the moral support which a knowledge of this reserve is presumed to give, and the restraint upon officers and men produced by the desire to retain it intact until the instant when its expenditure shall produce the greatest effect. This restraint, however, requires greater fire discipline on the part of the soldier. With guns of the repeating non-reserve type, a slightly more rapid fire can be obtained than from a reserve magazine rifle, but with the disadvantage that, at the very moment when the highest rate of firing is most desired it is probable that the soldier may find his gun either empty or only partially full.

The Krag-Jörgensen model.

The principal parts of the rifle are as follows:—The barrel (B, Fig. 20) is rolled from open-hearth steel of an elastic limit of 70,000 ℔ and an ultimate tenacity of 120,000 ℔ per square inch; annealed, bored, turned, chambered, tested at a high proof pressure, rifled, finished and oil-tempered to compress the bore initially; length 30 inches; rifling, uniform twist, one turn in 10 inches; 4 grooves ·004 of an inch deep; width of grooves, in terms of land, 3. The receiver (R) is a solid forging, machined to shape, having a hole or well to receive the bolt (O), the magazine (M) and a connecting channel enlarged in front so as properly to direct the passage of the cartridge from the magazine into the chamber (C) of the barrel. Excepting this channel, which is to the left, the bottom of the receiver is closed, and affords a smooth surface on which cartridges may be placed when using the arm as a single-loader. Fig. 20 is a sectional view of the operating parts, consisting of the bolt and magazine mechanism.

The bolt mechanism consists of the bolt (O), sleeve (V), extractor (X), safety lock (Y), firing pin (F), and striker (K), and main spring (Z). The bolt moves backwards and forwards and rotates in the well-hole of the receiver; it carries a cartridge, either from the

magazine, or one placed by hand in front of it, into the chamber, and supports its head when fired. The locking lug (L) will sustain any powder pressure liable to occur. The sleeve unites the parts of the bolt mechanism and directly carries the extractor; their rotation with the bolt is prevented by their engagement in the opening between the walls of the receiver. The hook of the extractor engages the rim of the cartridge case, and retains the head of the latter in

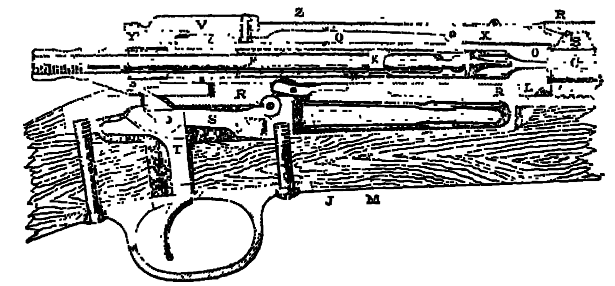

Fig. 20.

the countersink of the bolt until the case is thrown out by the ejector (J), operated at the end of the rear movement of the bolt by a groove in the under surface of the latter. The safety lock prevents accidental firing of the piece. The firing pin is made of two pieces—the rod, with its cocking-piece (P) below, and the separate striker (K) easily removed for repairs.

The gun having been discharged, to remove the empty cartridge, reload, and fire, the bolt mechanism operates as follows:—To open the bolt, raise the handle until it comes into contact with the sleeve, then pull directly to the rear until the locking lug strikes the shoulder of the receiver. Raising the handle rotates the bolt and separates the locking lug from the shoulder of its recess in the receiver. This separation is made easy by the slight inclination to the axis of the receiver of the vertical planes containing the rear surface of the locking lug and the shoulder of the recess. This rotation of the bolt causes a cocking cam on its rear under surface to force back the cocking-piece and firing pin, withdrawing the point of the striker and partially compressing the main spring (Z). Closing the bolt by a reverse motion compresses the main spring and cocks the piece completely, seats the cartridge in the chamber, and forces the extractor hook over the rim of the cartridge case. Pulling the trigger (T) releases the sear (S) and allows the firing pin and striker to move forward and strike the primer, firing the cartridge.

The magazine mechanism (Figs. 21 and 22) includes the gate (G), carrier (A), follower (W), magazine spring (N), hinge bar (H), and cut-off (U). Fig. 21 represents a cross section of the gun through the point of ejector, the bolt closed, the magazine filled and "off."

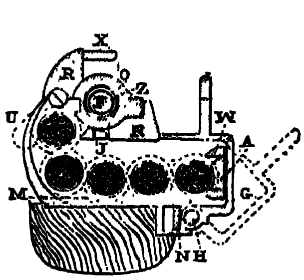

Fig. 21

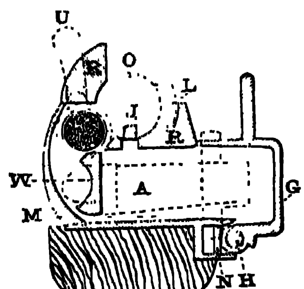

Fig. 22.

Fig. 22 shows the same cross section, when all but the last cartridge have been fired; the magazine is "on" and the bolt opened.

To charge the magazine, open the gate, by revolving it to the right on the hinge bar pin (see dotted lines, Fig. 21), insert the cartridges by hand or from a quick-loader, and then close the gate. As the gate is opened the carrier is retracted, leaving an unobstructed opening for the insertion of the cartridges. As the gate is closed the magazine spring swings the carrier into the magazine against the last cartridge inserted. When the thumb-piece of the cut-off is turned up the magazine is "on" (see Fig. 22). The spindle of the cut-off is then in its hole in the upper wall of the magazine channel and permits the top cartridge to rise high enough to be caught by the bolt in its forward movement. As the bolt is closed, this cartridge is pushed forward through the magazine channel and well of the receiver into the chamber, the point of the bullet being directed by a ramp on the receiver. When the cut-off thumb-piece is turned down the magazine is "off" (see Fig. 21). The point of the cut-off spindle then bears on the rim of the upper cartridge and holds it down in the magazine channel below the action of the bolt. The magazine mechanism then remains inoperative, and the arm can be used as a single-loader, the cartridges in the magazine being held in reserve. The stock with hand-guard is of walnut. The sight is graduated up to 2000 yards and provided with adjustment for windage, and jointed ramrod and oiler are carried in a hole in the butt. The bayonet is of the knife pattern and is carried in a metal scabbard with hook for attachment to woven cartridge belt holding 100 cartridges; weight of belt and cartridges, 7·4 ℔; weight of gun, 9·2 ℔. The United States magazine carbine, model 1899 (see Fig. 23) is practically the same as the rifle, using the same cartridge, giving about 80 feet per second less velocity. The stock and mountings are different, the barrel 22 inches long, and the total weight about 8 ℔.

The ball cartridge (see Fig. 24) consists of the case A, the bullet B, the primer C, and the charge of smokeless powder D. The bullet has a core of tin and lead composition, jacketed with cupro-nickel steel, weight 220 grains, velocity, fired in the rifle, 2200 feet per second. The maximum pressure is about 48,000 ℔ per square inch.

Forty-two aimed shots have been fired in two minutes with the arm, used as a single-loader, and 43 shots in the same time, using magazine. The maximum range is about 4400 yards. The penetration in white pine at 53 feet from the muzzle is about 56·5 inches.

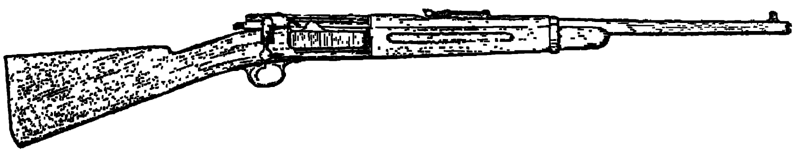

Fig. 23.

The infantry and foot artillery of the army are armed with the rifle, and the cavalry with the carbine; both of them passed successfully the crucial test of field service in the Spanish-American war. In addition to the ready use of the United States magazine rifle either as a single-loader with magazine in reserve or as a magazine arm, the following mechanical advantages are claimed for this gun:—(1) The mechanism requires but little force to operate. The first portion of the motion of unlocking the bolt and starting the empty cartridge shell, the final seating of the cartridge, and the locking,

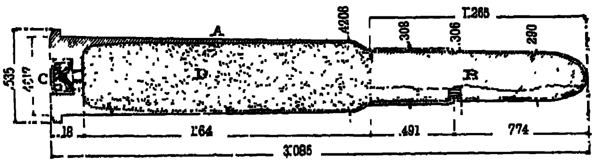

Fig. 24.

are accomplished by a motion of rotation, bringing into play the assistance offered by cams on the bolt and receiver. The compression of the main spring is given in the same manner, and not by a direct forward push of the hand against the main spring; (2) The locking lug which supports the bolt at discharge is at the forward end, with two supplementary supports in the nature of a rib and a lug farther to the rear; (3) The cut-off can be easily seen by the squad leaders and operated with full, partially full, or empty magazine; (4) The magazine is readily charged or replenished with single cartridges, or loaded by charging packets or quick-loaders, but these devices do not constitute any essential part of the mechanism; (5) The magazine can be charged whether the bolt is opened or closed, and whether the gun is adjusted for magazine or single-loader fire; (6) The bolt is in a single piece, without any separate bolt-head—the extractor does not rotate with the bolt; (7) If the bolt be not entirely closed upon pulling the trigger, the action of the main spring closes and securely locks the bolt before the firing pin can reach the primer; (8) In case of miss-fire the piece is cocked either by turning the handle up and down or by pulling the firing pin directly to the rear by means of its thumb-piece; (9) The mechanism is simple, strong, and composed of few parts, assembled with a minimum of screws or pins. The bolt can be readily removed and the bolt and magazine mechanisms easily dismounted or assembled without the use of special tools.

The United States magazine rifles and carbines, sabres and swords, are made at the Springfield Armoury, Springfield, Massachusetts, established in 1795. The capacity of the armoury is 500 magazine rifles per day. A small-arms plant of about the same size is being installed at Rock Island Arsenal and Armoury, Rock Island, Illinois.

Both these armouries are under officers of the ordnance department of the army. The national guard is armed with the Springfield rifle and carbine, calibre ·45, mostly model 1884. The model 1888 has a ramrod and bayonet combined.

The breech mechanism of the *Springfield rifle* consists of a receiver or frame, and a breech lock which rotates around a hinge pin perpendicular to the bore of the gun, above the bore and in front of the block. Fig. 25 represents a section of the breech mechanism by a vertical plane through the axis of the receiver, with the several parts projected thereon, showing their relative position.

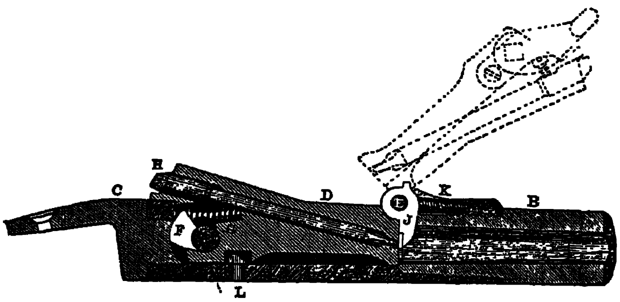

Fig. 25.

The barrel (B) is screwed into the receiver (A). The principal parts of the breech mechanism are the breech block (D), the hinge pin (E), the cam latch (F), the cam latch spring (G), the extractor (J), and the ejector spring and spindle (K). The breech block has an oblique hole through it for the firing pin (H). The hinge pin hole is elongated in the direction of the axis of the bore. The hinge pin passes through two holes in the lugs in the receiver. The cam latch locks the breech block in firing by entering a circular recess in the breech screw (C). The axis of the cam shaft projects on the right side, and to it is attached a thumb-piece, by which the cam latch is operated. This axis fits loosely. The extractor is mounted on the hinge pin, and part of its extremity is cut into such shape as to form, when in place, a part of the counterbore of the chamber, in which the rim of the cartridge rests. To load, the cartridge is inserted in the chamber in advance of the face of the breech block, when the block can be closed and locked (Fig. 26). When the piece is fired the breech block moves bodily slightly to the rear, owing to the elongation of the hinge pin hole. Owing to this motion of the block and to the loose fit of the cam latch shaft in its hole in the block, the pressure of the powder gas is transmitted directly through the breech block and the body of the cam latch to the breech screw, and there is no strain on the hinge pin or cam

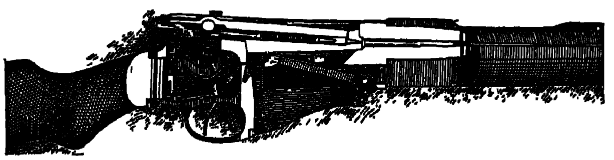

Fig. 26.—Action Closed.

latch shaft. The bearing of the cam is above the centre of the breech screw, the resistance of which tends to press the rear end of the breech block downward and forward under pressure of the powder gases. The block is opened by pressing the thumb-piece forward, which disengages the cam latch from the recess (Fig. 27). When the block has nearly completed its upward rotation it strikes against the projecting lug of the extractor and rotates the latter slowly, thus partly extracting the empty cartridge case. When the rear end of the ejector spindle passes below the axis of the hinge pin, the extractor becomes an ejector, and, with accelerated motion, completes the withdrawal of the shell and throws it against the ejector stud (L) and out of the gun. The Springfield rifle, without bayonet, weighs 9·3 ℔; the carbine, similar in construction, 7·9 ℔. The rifle cartridge consists essentially of a rim brass case, a lubricated bullet weighing 500 grains, and a charge of smokeless powder substituted for the 70 grains of black musket powder formerly used, giving the same velocity, 1316 feet per second, and about the same pressure, 25,000 pounds per square inch.

For uniformity the United States navy and marine corps have adopted the "Army Magazine Rifle," calibre ·30, which will gradually replace the United States navy rifle, model 1895, calibre 6 millimetres (approximately 0·2362).

This latter arm is known as the *Lee straight-pull rifle*, and is essentially a rapid-fire or repeating arm, rather than a magazine gun, since there is no provision for cutting off the supply of ammunition from the magazine and using the arm as a single-loader while the magazine contains cartridges. It may be used as a single-loader if the magazine be not charged, but in general it will be used as a repeater, five cartridges in a clip being entered in the magazine and the gun not being loaded until the charge is exhausted. In case loose ammunition is furnished, the magazine may be charged with single cartridges, any number from one to five being entered.

The motion of the hand, while not strictly "straight-pull," is such in effect that the operator makes no motion other than in a

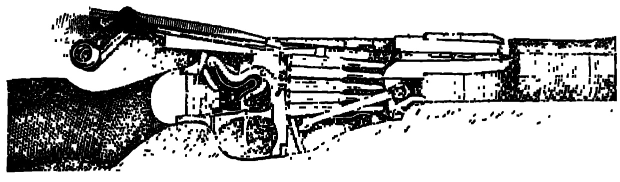

Fig. 27.—Action Open.

direction straight to the rear, the shape of the cam and the cam seat causing the rear end of the bolt to rise in the first part of the motion, carrying the hand with it. The extraction of the cartridge case is accomplished by the motion to the rear of the extractor, a hook-shaped piece moving in a groove on the left side of the receiver and acted upon by a flat spring. The extractor does not move to the rear until the bolt has moved about 1⅝ inches, when the front lug on the bolt strikes it and draws it to the rear with a sudden jerk. The ejection of the cartridge case is accomplished when the bolt has been fully drawn to the rear by the tail of the extractor striking the bevelled front face of the bolt-stop, which arrests it suddenly and imparts to it a quick, short, transverse motion, which ejects the empty case. The retraction of the firing pin is caused by the first motion of the lever handle, which brings the nib of the lever handle to bear against the cocking toe of the firing pin and pushes it to the rear, the bolt during this time having practically only an upward motion of its rear part. At the same time the nib of the lever handle slips into a notch in the cocking toe of the firing pin, preventing any forward motion of the firing pin with respect to the bolt. The cocking of the firing pin is caused by the sear arresting the forward motion of the firing pin (in closing the breech) while the bolt moves on, compressing the main spring. The locking lug is part of the bolt, and is a rectangular lug on the under face. In closing the breech, in the final motion of the bolt (which is down), the locking lug is seated and bears against a corresponding shoulder in the lower part of the receiver. In opening the breech, the first motion of the bolt is upward, raising the bolt so that the locking lug clears the shoulder and the bolt can move to the rear. Safety devices are provided to prevent the bolt from being opened until the piece is fired, and to lock the firing pin when the gun is cocked.

Cartridge.—A cannelured cartridge, weight about 309 grains, having a charge of 33 grains of smokeless powder and a hardened lead bullet, with a copper jacket plated with tin, weighing 112 grains, is used. The maximum chamber pressure is 49,000 ℔ per square inch. The bullet has a velocity of 2550 feet (777·24 metres) per second at 60 feet from muzzle, with the consequent advantage of a very flat trajectory. The weight of the loaded belt,

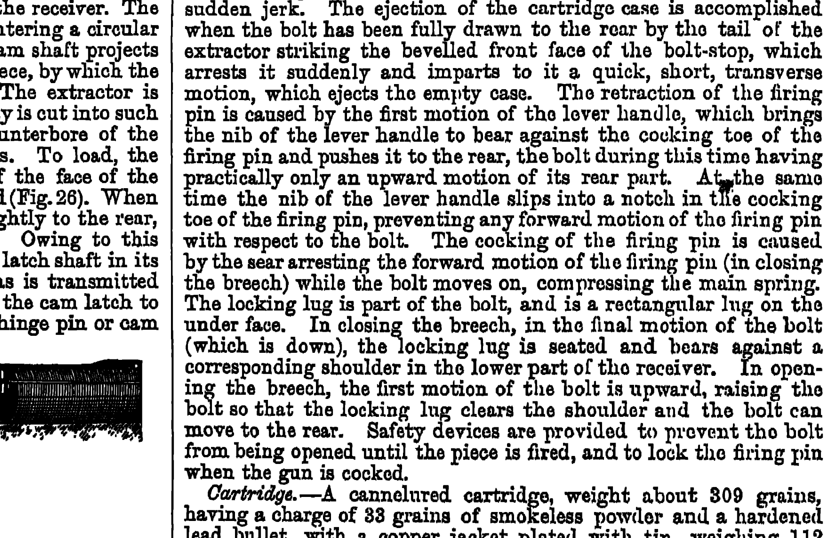

Fig. 28.—Action closed.

containing 180 cartridges in 12 pockets of 3 clips each, is about 9¾ ℔.

The *Winchester repeating rifle, calibre* ·30, *model* 1895, is a fixed box magazine lever-action gun (Figs. 28 and 29).

The receiver, open at the top, permits the symmetrical lockings of the breech-bolt. The first opening motion of the lever withdraws the trigger from contact with the sear, before the gun is

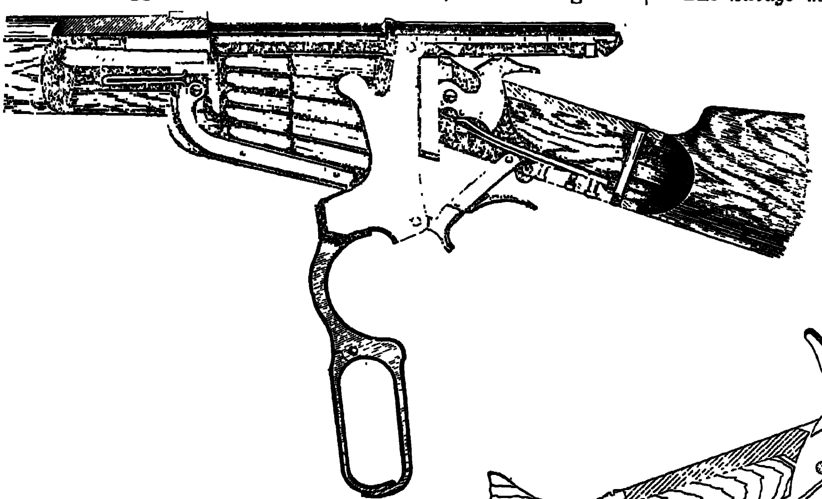

Fig. 29.—Action open.

unlocked, so that it is impossible to fire the gun except when fully locked. The continued opening motion of the lever draws down the locking bolt and withdraws the breech-bolt, cocking the gun and ejecting the cartridge or fired shell. The breech-bolt, passing over the hammer, presses the firing pin lock against the latter, and makes fast the firing pin. When the breech-bolt is in its rearmost position, the hammer is made to hold it open by contact, so that the magazine may be easily loaded. When in this position, the upper cartridge in the magazine is so presented as to engage the breech-bolt.

The closing action of the lever carries forward the breech-bolt, forcing the cartridge out of the magazine into the chamber. After the breech-bolt has reached its closed position, the locking bolt is lifted into place, first locking the gun and afterwards unlocking the firing pin. The final closing movement of the lever presents the trigger against the sear, leaving the gun in position for firing. The magazine, of the box type, contains five cartridges, and the number in the magazine can always be known by opening the gun, if light serves, or by feeling, if light fails. The magazine follower presents the cartridges to the lower front edge of the breech-bolt in position to be forced into the chamber, and is arranged to prevent the escape of the cartridge following before the preceding one is in the grasp of the extractor, thus preventing the jamming of the gun by false movement.

The *Remington-Lee rifle* (see Fig. 30) is a box magazine rifle, arranged to load with a filler or clip containing five cartridges. It is manufactured to fire the ·30 calibre army, the 6 millimetre navy, and other small-calibre smokeless cartridges.

This rifle is also made of the same general form, with a flat cut-

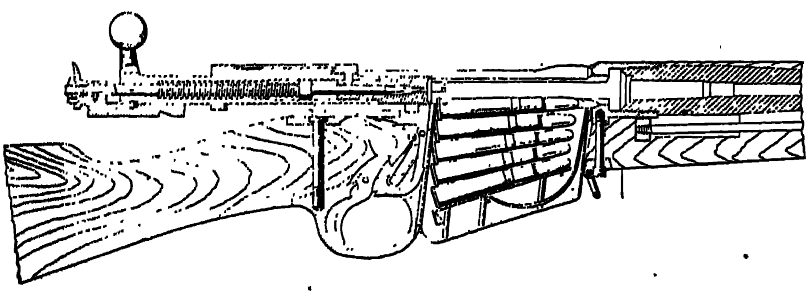

Fig. 30.

off which can be pressed in, forming a false bottom for the receiver, so as to convert the gun into a single-loader, or with detachable magazines, a number of which, filled with cartridges, can be carried in a belt, so that the rifle can be used as a repeater for rapid continuous fire. The Remington Armoury, at Ilion, N.Y., also manufactures the single-loader small-bore rifle for smokeless powder, to meet the demand on the part of Mexico and Central and South American countries for a simple system for certain troops (Fig. 31).

The *Savage magazine rifle, model* 1899, is a "hammerless," lever-action repeating arm, with a revolving cartridge carrier in a fixed magazine under the receiver for five rimmed cartridges, charged one at a time by hand. It can be used readily as a single-loader (Figs. 32 and 33).

The magazine is charged while the system is open. The finger-lever (A) is opened to its fullest extent (see Fig. 32). The cartridges are inserted into the magazine by pushing them down and under the catch (B) on the automatic cut-off (C). A sixth cartridge can be placed in the breech-opening (D) above the catch (B). On closing the finger-lever (A) the cartridge in the

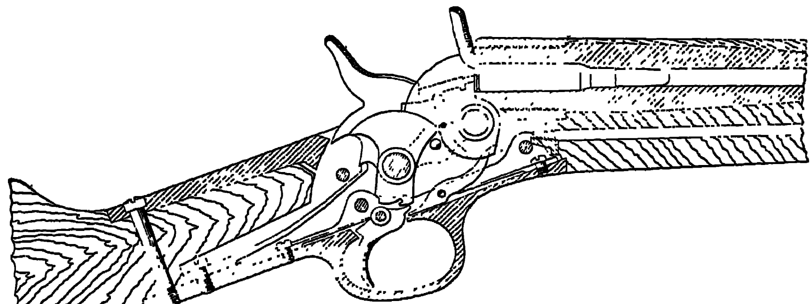

Fig. 31.

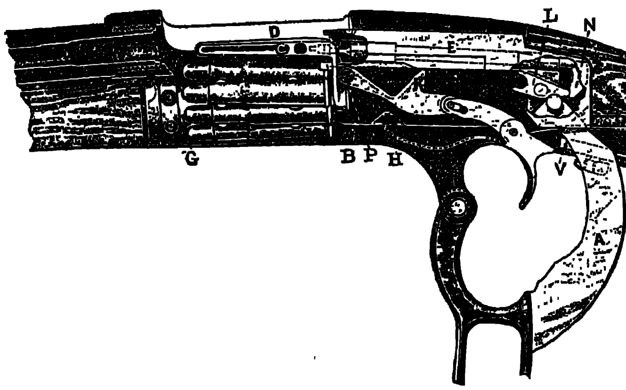

Fig. 32.—Action Open.

breech-opening (D) will be carried forward by the breech-bolt (E) into the chamber of the barrel, making the rifle ready to fire.

In using the rifle as a single-loader, the placing of a cartridge in the breech-opening (D) forces the automatic cut-off (C) back into its recess in the receiver, retiring the uppermost cartridge in the magazine below the line of movement of the breech-bolt (E), so that only the cartridge in the breech-opening will be engaged by the breech-bolt on its forward travel. For magazine fire, there being no cartridge in the breech-opening (D), but one or more cartridges in the magazine, the breech-bolt (E) on its forward travel, will engage and carry forward into the barrel chamber the uppermost cartridge in the magazine. The automatic cut-off (C) has on its face a projection which ejects the fired shells, after being withdrawn by the extractor (F) on the breech-bolt (E). The numerals on the magazine carrier (G) show, through the opening in the receiver, the number of cartridges contained in the magazine. The breech-bolt (E) is positively operated by the finger-lever (A), without any intermediate mechanism, and when closed, ready for firing, is immovably locked by the finger-lever resting on a solid projection at (H) in the receiver. The recoil of the discharge is supported at (U), and is in the direct line of the strain. The breech-bolt (E) carries the extractor (F), a retractor (L), the hammer (N), the main spring (O), and indicator (Y). The firing mechanism is operated as follows:—If the rifle has been fired, the act of opening the finger-lever, and thereby the breech-bolt, locks a retractor (L) by engagement with the sear pin (P), and the hammer (N, with firing pin) is positively retracted and held back from the

face of the breech-bolt. The closing movement of the breech-bolt brings the hammer (N) in engagement with the face of the sear (K), compressing the main spring (O), and the rifle is fully cocked. The

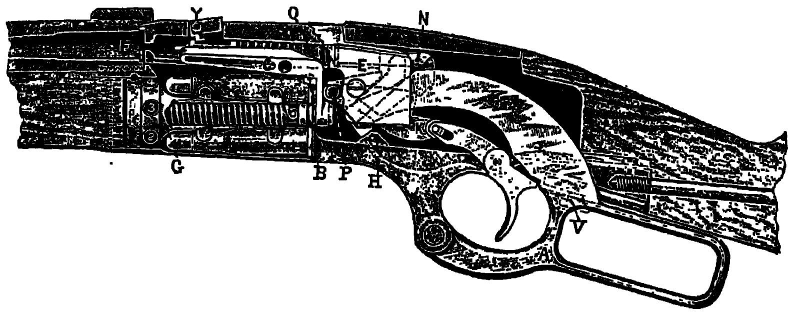

Fig. 33.—Action closed.

action can be locked by pushing forward the lock (V), which locks the trigger and lever. The indicator (Y) shows the position of the firing mechanism.

Revolvers.—The *Colt's double-action revolver, calibre* ·38, *model* 1896, is used in the United States army. The United States navy revolver, calibre ·38, model 1895, is practically the same arm. The revolver can be cocked by hand before each fire, or the cocking and firing can be accomplished by simply pulling the trigger.

Revolvers.

The revolver consists of the barrel (B), the cylinder (C) with six chambers, the frame (F), and the firing mechanism, all of steel. The muzzle velocity with a charge of 16 grains of black powder and a bullet of 150 grains of lead, is about 708 feet per second, giving at 25 yards a penetration of about 5 inches in pine. Eighteen shots can be fired in 44 seconds, loading each chamber

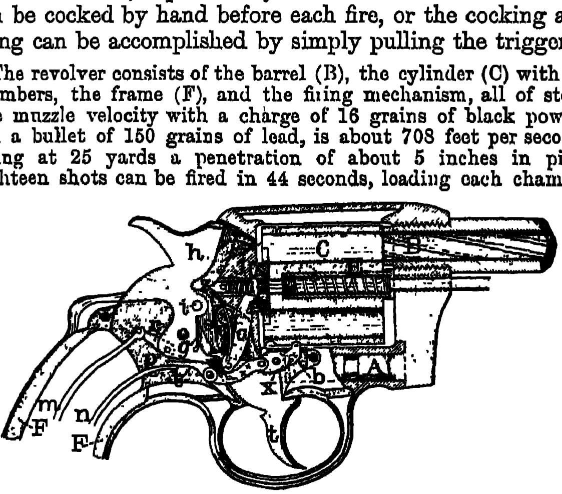

Fig. 34.

separately, and beginning and closing with cylinder closed and chambers empty (Figs. 34 and 35).

The lock mechanism consists of the hammer (*h*), with its stirrup (*r*), stirrup pin (*p*), strut (*s*), strut pin (*i*), strut spring (*g*); the trigger (*t*); the rebound lever (*l*); the hand (*a*), with the spring (*z*); the cylinder bolt (*b*), with its spring (*x*); the locking lever (*v*); the main spring (*m*), and rebound lever spring (*n*). The hammer (*h*), trigger (*t*), and rebound lever (*l*) are pivoted on their respective pins, which are fastened in the left side of the frame. The lower end of the rebound lever spring (*n*) is secured to the frame and the free end bears under the rear end of the rebound lever so that the latter, when the trigger is released, cams the hammer back to its safety position, and forces the trigger forward. Pressure upon the trigger causes its upper edge to engage the strut, and thereby raises the hammer until nearly in the full-cock position, when the strut will escape from the trigger, and the hammer, under the action of the main spring, will fall and strike the cartridge. A projection on the upper part of the trigger, working in a slot in the frame, prevents the cylinder from making more than one-sixth of a revolution at a time by entering one of the grooves nearest the rear end of the surface of the cylinder. When the cylinder is swung out of the frame, the parts are arranged to prevent the cocking of the hammer. The cylinder bolt is pivoted on the trigger pin, and its spring, bearing on the rebound lever arm, causes the nose of the bolt to project through a slot in the frame ready to enter one of the rectangular cuts in the cylinder surface. During the first movement of the trigger in cocking the revolver, the nose of the bolt is withdrawn, allowing free rotation of the cylinder. The object of the bolt is to prevent rotation of the cylinder in transportation. The hand is attached by its pivot to the trigger, and, as the latter swings on its pin when the hammer is being cocked, the hand is raised and revolves the cylinder, and also serves to lock the cylinder in position at the time of firing. An abutment on the side plate supports the hand spring in rear. The spring ensures the engagement of the hand with the ratchet (*y*). The revolver is cocked by hand by withdrawing the hammer by the pressure of the thumb until its full-cock notch engages in the rear sharp corner of the trigger. Pulling the trigger then releases the hammer, allowing its firing pin (*f*) to move forward and strike the cartridge.

The locking lever is pivoted by its screw in a recess in the left side of the frame, and so connected with the latch that it locks the hammer and trigger when the latch is pushed to the rear for opening the cylinder, and does not unlock them until the cylinder is positively closed and is locked by the latch. The cylinder revolves and is supported on a central arbour of the crane (E). The crane fits in a recess in the frame below the barrel and turns on its pivot arm (A). The ejector rod with its spring passes through the centre of the cylinder arbour and is terminated in rear by the ejector with a ratchet (*y*). Pushing against the front end of the ejector rod will empty the chambers, the cylinder being swung out for loading. The thumb-piece of the latch (*j*) slides to the rear in the left side of the frame, unlocking the cylinder for opening, but upon closing the cylinder, the body of the latch firmly enters a recess in

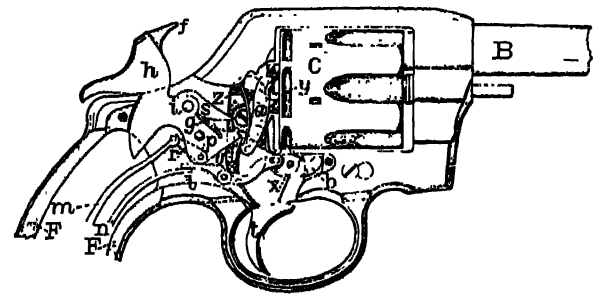

Fig. 35.

the ejector, locking the cylinder in position for firing. The barrel is firmly screwed to the frame. The Smith and Wesson revolvers are essentially of the divided frame type, the barrel and cylinder tipping downwards on a pivot in the lower forward part of the frame, at the time of loading the cartridges or ejecting the shells. The ejection is automatic.

The Colt Automatic Pistol, calibre ·38. The action of this pistol is semi-automatic, the trigger being slightly pulled for each shot fired. The magazine being charged with cartridges and in position, the first cartridge is loaded into the barrel by pulling the slide to the rear, and fired by pulling the trigger, when the operations of extracting the empty cartridge case, reloading a new cartridge into the barrel, and cocking the piece, are performed automatically.

The pistol (Figs. 36 and 37) consists of four main parts: the frame (F), the barrel (B), the slide (S), and the magazine (M). The frame

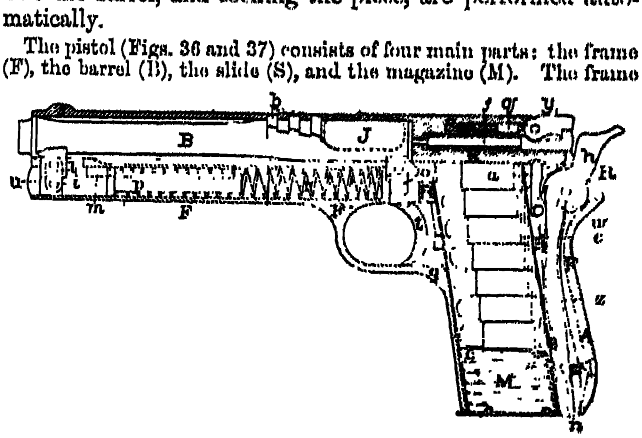

Fig. 36.

forms, at its rear and lower part, the handle (A), which is hollow, and contains the seat for the magazine. After being charged with seven cartridges, the magazine is seated from below and held in place by the magazine catch (*n*), which slightly projects from the bottom of the handle. This projection serves to release the magazine from the catch, when it can be readily drawn from the

handle for re-charging. In front of the handle is the trigger guard (g), in which the trigger (t) is found, and in the rear and above the grip the firing mechanism is placed in the part of the frame called the receiver (R). The firing mechanism consists of the hammer (h), the sear (w), the trigger (t), a safety device (a), the main spring (z) and sear spring (e), the lower part of the latter serving to operate the magazine catch. The top of the receiver extends forward from the handle, and to it the barrel is attached by two short links, one (l) near the front end of the barrel, and the other (o) at its rear end; these links are pivoted to the receiver and also to the barrel, and allow the barrel to swing rearwards thereon. As both links are of the same length, the rearward movement of the barrel in swinging on these links carries the barrel slightly downwards, but keeps its longitudinal axis in parallel positions during all its movements. Below the barrel the receiver forms a tubular seat for the retractor spring (r), which in front is closed by a plug (u) fastened in the receiver by the lower pivot-pin (i) of the front barrel-link. The upper surface of the receiver and two longitudinal grooves on its sides form the seat for the slide which is guided thereon in its rearward and forward movements. The rear part of the slide forms the bolt or breech block (K), and the front part forms a partly tubular cover (s) which encloses the barrel. In the forward part of the receiver is a transverse mortice extending through the retractor spring seat, and transverse recesses in the forward part of the slide serve to admit a key (m) which, passing through the sides of the slide and through the mortice, serves to lock the slide to the frame. The retractor spring (r), in its seat in the frame, consists of a spiral spring, the rear end of which rests against the receiver, and the front end of which

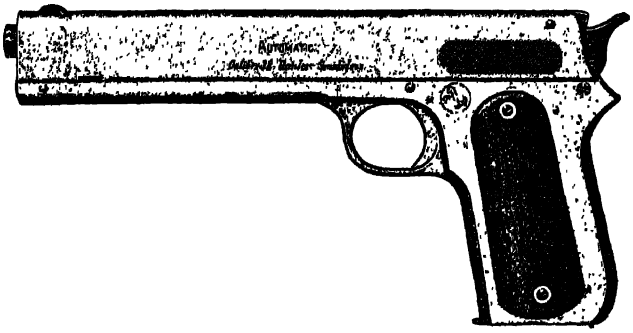

Fig. 37.

carries a piston (p). The rear face of the key (m) has a slight recess, and when the key is in its place the front end of the retractor spring rests in this recess, thereby confining the key laterally. The tension of the retractor spring is exerted to force the key and the slide to their forward position. Upon the barrel are provided three transverse ribs (b), and in the interior of the slide are three corresponding recesses. These serve to lock the barrel and the slide firmly together when in their forward position. Between the locking recesses and the bolt, the slide has an opening on its right side for the ejection of the cartridge cases (J), and the bolt is provided with an extractor, a firing pin (f), a firing pin retraction spring (q), and a firing pin lock (y). This latter is pivoted at the rear end in the top of the slide, and when depressed, locks the firing pin in its retracted position, thus preventing its point from coming in contact with the cartridge primer. When raised, the firing pin lock releases the firing pin, and in this position also serves as the rear sight, being provided on the top with a sighting notch.

The *operation* of the pistol is as follows:—When a charged magazine (M) is inserted, the slide (S) is drawn once to the rear by hand, thereby cocking the hammer (h). In this position of the slide, the carrier (c) and carrier spring in the magazine raise the topmost cartridge so as to bring it into the path of the bolt (K). On releasing the slide, it, with the bolt, is carried forward by the retractor spring (r), and during this movement the bolt forces the topmost cartridge into the barrel (B). As the slide approaches its forward position the front of the bolt encounters the rear end of the barrel and forces the latter to its forward position. During this forward movement the barrel swings forward and upward on the links (l, o), and thus the locking ribs (b) on the barrel are carried into the corresponding locking recesses in the slide. The barrel and slide are thereby positively interlocked, and the pistol is ready for firing.

A slight pull on the trigger (t) now serves to move the sear (w) so as to release the hammer (h) and fire a shot. The force of the powder gases driving the bullet from the barrel is exerted rearwardly against the bolt, and, overcoming the inertia of the slide and the tension of the retractor spring, causes the slide and the barrel to recoil together. After moving rearwards together, for a distance, enough to ensure the bullet having passed from the barrel, the downward swinging movement of the barrel releases the latter from the slide and stops the barrel in its rearmost position. The momentum of the slide causes the latter to continue its rearward movement, thereby again cocking the hammer and compressing the retractor spring, until, as the slide arrives at its rearmost position, the empty shell is ejected from the side of the pistol and another cartridge raised in front of the bolt. During the return or forward movement of the slide, caused by the retractor spring, the cartridge is driven into the barrel, and the slide and barrel are interlocked, thus making the pistol ready for another shot. These operations may be continued so long as there are cartridges in the magazine, each discharge requiring only the slight pull on the trigger. The pistol is provided with a safety device (a) which makes it impossible to pull the trigger so as to release the hammer unless the slide and barrel are in their first forward position, and safely interlocked. (J. T. T.)

Smart, Henry (1813–1879), English organist and musical composer, born in London, 26th October 1813, was the son of a violinist, and nephew of Sir George Smart. After studying for the legal profession, Smart turned to music and worked with W. H. Kearns. In 1831 he became organist of Blackburn Parish Church, where he wrote his first important work, a Reformation anthem; then of St Giles's, Cripplegate; St Luke's, Old Street; and finally of St Pancras, in 1864, which last post he held at the time of his death, 6th July 1879, less than a month after receiving a Government pension of £100 per annum. Although Smart is now known chiefly by his compositions for the organ, which are numerous, effective, and very melodious if not strikingly original, he wrote many vocal works, including some of the best specimens of modern part songs. His cantata *The Bride of Dunkerron* was written for the Birmingham Festival of 1864; *Jacob* for Glasgow, in 1873; and his opera, *Bertha*, was produced with some success at the Haymarket in 1855. In the last fifteen years of his life Smart was, to all intents and purposes, blind.

Smell. See PHYSIOLOGY, *Special Senses.*

Smetana, Friedrich (1824–1884), Bohemian composer and pianist, was born at Leitomischl, 2nd March 1824. He made such rapid progress in his studies under Ikavec, at Neuhaus, that at the age of six he appeared in public as pianist so successfully that his father's opposition to a musician's career was overcome. He then went to Proksch, at Prague, until, a spirit of restlessness seizing him, he left for Leipzig to make the acquaintance of Schumann and Mendelssohn. Limited means prevented him from studying with the latter, and he returned to Prague, where he at once became Konzert-meister to the Emperor Ferdinand. In 1848 he married Katharin Kólar, pianist, and with her founded a music school at Prague. At the same time he met Liszt, who subsequently influenced him greatly, and with whom he afterwards stayed at Weimar. In 1856 Smetana accepted Alexander Dreyschock's suggestion to go as conductor of the Philharmonic Society at Gothenburg. There he remained five years, when, owing to his wife's ill-health, he returned to Prague after a successful concert tour. The death of his wife at Dresden on their return, caused Smetana to change his mind, and he went back to Sweden. But the opening of the Interims Theater in 1866, and the offer of its conductorship, induced his return. In Sweden he had already written *Hakon Jarl*, *Richard III.*, and *Wallenstein's Lager*, and had completed his opera *Die Brandenburger in Böhmen* (5th January 1866). Five months later it was followed by his best-known opera, *Die Verkaufte Braut*, and in 1868 *Dalibor* was given. Between 1874 and 1882 he produced *Zwei Witwen*, *Hubicka* (*Der Kuss*), *Tajewstvi* (*Das Geheimniss*), *Certova Stena*, and *Die Teufelsmauer*, as well as the "grand prize" opera *Libuse*, written for the opening of the National Theatre at Prague, 11th June

1881. In *Die Teufelsmauer* were clear signs of decay in Smetana's powers, he having already in 1874 lost his sense of hearing. To celebrate his sixtieth birthday a fête was arranged by the combined Bohemian musical societies; but on that day Smetana lost his reason and was removed to a lunatic asylum, where he died, 12th May 1884. A great deal of his pianoforte music is interesting, the *Stammbuchblätter*, for example; while his series of symphonic poems, entitled *Mein Vaterland* (*Vlast*), and his beautiful string-quartet, *Aus meinem Leben*, have made the tour of the civilized world. He was an admirable pianist, and in many ways justified his countrymen's title of the "Czechish Beethoven." (R. H. L.)

Smethwick, a municipal borough (1899) in the Handsworth parliamentary division of Staffordshire, England, 3 miles west of Birmingham by rail. Among modern buildings are two Established churches and a Roman Catholic church. Victoria Park (35 acres) was opened in 1888, and West Smethwick Park in 1895. Area, 1872 acres. Population (1891), 36,170; (1901), 54,560.

Smichow, chief town of a government district in Bohemia, Austria, on the left bank of the Moldau, opposite Prague, with which it is connected by a bridge and in which it is now practically merged. Population (1890), 32,646; (1900), 47,094, mostly Czech.

Smiles, Samuel (1812——), British author, was born at Haddington, 23rd December 1812. He was educated there and at Edinburgh University, where he studied medicine; and for some years practised as a surgeon at Haddington. Abandoning the medical profession he took to journalism, and from 1838 till 1844 edited the *Leeds Times*. Though he gave up regular journalism in 1844, he continued to be a frequent contributor to periodicals. From 1845 till 1854 he was secretary of the Leeds and Thirsk Railway, and from 1854 till 1856 of the South-Eastern Railway. In 1857 he published a *Life of George Stephenson*, which was the precursor of a series of biographies from the world of industry, such as *Lives of the Engineers* (3 vols., 1861–62), *Industrial Biography* (1863), *Lives of Boulton and Watt* (1865), *The Life of a Scotch Naturalist* (Thomas Edwards) (1876), *Life and Labour* (1887), *A Publisher and his Friends* (a history of the house of Murray, under "glorious John") (1891), *Jasmin* (1891), *Josiah Wedgwood* (1894). In 1859 appeared *Self-Help*, a volume of popular ethics which was very widely read. Its success prompted successors, such as *Character* (1871), *Thrift* (1875), *Duty* (1880). Dr Smiles (who was made hon. LL.D. of Edinburgh University) also published two works dealing with the history of the Huguenots, and a *History of Ireland*.

Smith, Goldwin (1823——), British historian, educational reformer, and publicist, was born at Reading on 13th August 1823. He was educated at Eton and Magdalen College, Oxford, and after an undergraduate career of exceptional brilliancy was elected to a fellowship at University College. A Liberal in his outlook, not only on politics but on every aspect of life, he threw his keen intellect and trenchant style into the cause of university reform, the leading champion of which was another fellow of University College, Arthur Penrhyn Stanley. On the Royal Commission of 1850 to inquire into the reform of the university, of which Stanley was secretary, he served as assistant-secretary; and he was secretary to the commissioners appointed by the Act of 1854. His position as an authority on educational reform was further recognized by a seat on the Popular Education Commission of 1858. In 1868, when the question of reform at Oxford was again growing acute, he published a brilliant pamphlet, entitled *The Reorganization of the University of Oxford*. Besides the abolition of tests, effected by the Act of 1871, many of the reforms there suggested, such as the revival of the faculties, the reorganization of the professoriate, the abolition of celibacy as a condition of the tenure of fellowships, and the combination of the colleges for lecturing purposes, were incorporated in the Act of 1877, or subsequently adopted by the University. Among those that have not yet found favour are "the creation of a responsible department of government with adequate powers for the visitation of endowed institutions," to which would be transferred all powers now vested in the Privy Council or in the Visitors of Colleges, "with regard to the amendment of statutes or the appropriation of revenues"; the abolition of religious tests in the theological faculty, and its conversion into a department of unfettered research; the conferment only of real degrees; the election of the vice-chancellor by congregation; the abolition of the Hebdomadal Council, and what he calls "the most indispensable though perhaps the most difficult reform," the abolition of the Convocation of non-resident graduates. He gave the counsel of perfection that "pass" examinations ought to cease; but he recognized that this change "must wait on the reorganization of the educational institutions immediately below the University, at which a passman ought to finish his career." His aspiration that colonists and Americans should be attracted to Oxford has been realized by Mr Rhodes's will. On what is perhaps the vital problem of modern education, the question of ancient *versus* modern languages, he pronounces that the latter "are indispensable accomplishments, but they do not form a high mental training"—an opinion entitled to peculiar respect as coming from a president of the Modern Language Association. The same conspicuous openness of mind appears in his judgment, delivered after he had held the regius professorship of Modern History at Oxford from 1858 to 1866, that "ancient history, besides the still unequalled excellence of the writers, is the best instrument for cultivating the historical sense." But though penetrated with the sense that all modern intellect and art derive their greatness from Greece and Rome, no man's writings "palpitate with actuality" more than his, nor has any one wielded a more eager weapon on every battlefield of political or social reform.

The multiplicity of his interests, indeed, injured his work as a historian; he did not, like Gibbon, devote his life to one monumental work that should preserve his fame to future generations. His chief historical writings—*The United Kingdom: a Political History* (1899), and *The United States: an Outline of Political History* (1893)—though based on thorough familiarity with their subject, make no claim to original research. Both are remarkable examples of terse and brilliant narrative, and of the subordination of details to a consistent effect. The *United States* stands without a rival in its kind; the *United Kingdom* naturally challenges comparison with Green's *Short History of the English People*, but its insistence on the political rather than the picturesque aspect of history, its view of affairs from the arena no less than from the study, and its fuller treatment of the great problems of the 19th century, make it rather the complement of Green's work than the rival. A peculiar breadth of outlook is lent to both his histories by his equal familiarity with the conditions of the Old World and the New. The outbreak of the American Civil War proved a turning-point in his life. Unlike most men of the ruling classes in England, he warmly championed the cause of the North, and by his pamphlets, especially one

entitled *Does the Bible sanction American Slavery?* (1863), played a chief part in converting English opinion to what was afterwards universally recognized as the right side. Visiting America on a lecture tour in 1864, he received an enthusiastic welcome, and was entertained at a public banquet in New York. In 1868 he threw up his career in England and settled in the United States, where he held the professorship of English and Constitutional History at Cornell University till 1871. In that year he removed to Toronto, where he edited the *Canadian Monthly*, and subsequently founded the *Week* and the *Bystander*. He did not, however, cease to take an active interest in English politics. He had been a strong supporter of Irish Disestablishment, but he refused to follow Gladstone in accepting Home Rule. He expressly stated that "if he ever had a political leader, his leader was John Bright, not Mr Gladstone." Speaking in 1886, he referred to his "standing by the side of John Bright against the dismemberment of the great Anglo-Saxon community of the West, as I now stand against the dismemberment of the great Anglo-Saxon community of the East." These words form the key to his views of the future of the British Empire. He always maintained that Canada, separated by great barriers, running north and south, into four zones, each having unimpeded communication with the adjoining portions of the United States, was destined by its natural configuration to enter into a commercial union with them, which would result in her breaking away from the British empire, and in the union of the Anglo-Saxons of the American continent into one great nation. These views are most fully stated in his *Canada and the Canadian Question* (1891). Though describing himself as "anti-Imperialistic to the core," he was yet deeply penetrated with a sense of the greatness of the British race. Of the British empire in India he said that "it is the noblest the world has seen. . . . Never had there been such an attempt to make conquest the servant of civilization. About keeping India there is no question. England has a real duty there." His fear was that England would become a nation of factory-workers, thinking more of their trade-union than of their country. These forebodings were intensified in his *Commonwealth or Empire?* (1902)—a warning to the United States against the assumption of imperial responsibilities. Among other causes that he powerfully attacked were liquor prohibition, female suffrage, and State Socialism. All these are discussed in his *Essays on Questions of the Day* (revised edition, 1894). He also published sympathetic monographs on *Cowper* and *Jane Austen*, and attempted verse in *Bay Leaves* and *Specimens of Greek Tragedy*. In his *Guesses at the Riddle of Existence* (1897), he abandons the faith in Christianity expressed in his lecture of 1861 on Historical Progress (where he forecast the speedy reunion of Christendom on the "basis of free conviction"), and writes in a spirit "not of Agnosticism, if Agnosticism imports despair of spiritual truth, but of free and hopeful inquiry, the way for which it is necessary to clear by removing the wreck of that upon which we can found our faith no more." Particularly characteristic are his two little books, designed primarily as guides for American visitors to England. *Oxford and her Colleges*, with its blending of complete sympathy and knowledge, stands alone in its way. In *A Trip to England* he has, with a few masterly strokes, drawn a perfect miniature of English society and English landscape.

Smith, Sir William (1813–1893), lexicographer, was the eldest son of William Smith, of Enfield, a Nonconformist. He was originally destined for a theological career, but instead took up law, and was articled to a solicitor. In his spare time he taught himself classics, with such success that, when he entered University College as a student, he carried off both the Greek and Latin prizes. After pursuing his studies there he obtained a post at University College school, and at the same began to write on scholarly subjects and publish editions of the classics. He next turned his attention to that branch of work for which he is chiefly known—the collection of information in lexicographical form. His first attempt was the *Dictionary of Greek and Roman Antiquities*, which appeared in 1842. The greater part of this was written by himself. In 1849 followed the *Dictionary of Greek and Roman Biography*, and the *Greek and Roman Geography* in 1857. In this work some of the leading scholars of the day were associated with him. In 1850 he published the first of the school dictionaries; and in 1853 he began the Principia Series, which marked a distinct step in the school teaching of Greek and Latin. Then came the *Students' Manuals of History and Literature*, in which the Greek History was the editor's own work. In carrying out this task Smith was most ably seconded by Murray, the publisher, who, when the original publishers of the dictionaries got into difficulties, volunteered to take a share in the undertaking, and contributed largely to the great success attained by these encyclopædic volumes. The most important, perhaps, of the books edited by William Smith were those that dealt with ecclesiastical subjects. These were the *Dictionary of the Bible* (1860–65), the *Dictionary of Christian Antiquities* (1875–80), undertaken in collaboration with Archdeacon Cheetham; and the *Dictionary of Christian Biography* (1877–87), jointly with Dr Wace. The *Atlas*, on which Sir George Grove collaborated, appeared in 1875. All these books have become standard works, and the Dictionaries of the Bible and the Greek and Roman Antiquities appeared in new and revised editions before the editor's death. From 1853 to 1869 Smith was classical examiner to the University of London, and on his retirement he became a member of the Senate. He sat on the Committee to inquire into questions of copyright, and was for several years Registrar of the Royal Literary Fund. He edited Gibbon, with Guizot's and Milman's notes, in 1854–55. In 1867 he became editor of the *Quarterly Review*, which he directed until his death in 1893 with marked success, his remarkable memory and accuracy, as well as his tact and courtesy, specially fitting him for such a post. He was D.C.L. of Oxford and Dublin, and the honour of knighthood was conferred on him the year before his death. (A. Z.)

Smith, William Henry (1825–1891), English man of business and statesman, was born in London 24th June 1825. His father was the founder of the great distributing firm of W. H. Smith & Son, in the Strand, and at an early age he became a partner and devoted himself to the business. He betrayed no political aspirations until 1865, when he came forward as a Conservative to contest Westminster against John Stuart Mill and the Hon. Mr Grosvenor. Defeated on that occasion, he triumphed in 1868, winning a victory when his party was in general vanquished on all sides. The prestige thus obtained, and the accident of representing so important a constituency, combined with wealth and his business abilities to recommend him to Disraeli, who in 1874 made him secretary to the Treasury. In 1877 he gained cabinet rank as first lord of the Admiralty; in 1885 he was successively secretary for War and chief secretary for Ireland; in 1886 he was again at the War Office; and when late in that year Lord Randolph Churchill's

resignation necessitated a reconstruction of the ministry, Mr Smith found himself first lord of the Treasury and leader of the House of Commons. He was no orator, and made no pretence to genius, but his success in these high offices was complete, and was admittedly due, not merely to business ability, but to the universal respect which was gained by his patience, good temper, zeal for the public service, and thorough kindness of heart. He died at Walmer Castle (which he occupied as Warden of the Cinque Ports) on 6th October 1891. In recognition of his services, a peerage in her own right was conferred on his widow, with the title of Viscountess Hambleden.

Smith, William Robertson (1846-1894), Scottish philologist, physicist, archæologist, Biblical critic, and the editor, from 1880, of the 9th edition of this Encyclopædia, was born 8th November 1846 at Keig in Aberdeenshire, where his father was Free Church minister. He was educated at home and at Aberdeen University, where he attained the highest academic distinctions, winning among other things the Ferguson mathematical scholarship, which is open to all graduates of Scottish universities under three years' standing. In 1866 he entered the Free Church College at Edinburgh as a student of theology. During two summer sessions he studied philosophy and theology at Bonn and Göttingen, making friends in all branches of learning. From 1868 to 1870 he acted as assistant to the professor of natural philosophy in Edinburgh University. During this period he was not only most successful as a teacher, but produced much original work — especially in the experimental and mathematical treatment of electricity — which is still regarded as standard. In 1870 he was appointed and ordained to the office of professor of Oriental languages and Old Testament exegesis at the Free Church College, Aberdeen, and here he began that series of theological investigations which, characterized as they were by learned research and the use of the most scientific methods, were destined to make his name famous. He was the pupil and personal friend of many leaders of the higher criticism in Germany, and from the first he advocated views which, though now widely accepted, were then regarded with apprehension. The articles on Biblical subjects which he contributed to the 9th edition of the *Encyclopædia Britannica* distressed and alarmed the authorities of the Free Church. In 1876 a committee of the General Assembly of that Church reported on them so adversely that Smith demanded a formal trial, in the course of which he defended himself with consummate ability and eloquence. The indictment dropped, but a vote of want of confidence was passed, and in 1881 Smith was removed from his chair. During this long struggle he was sustained by the conviction that he was fighting for freedom, and at the end of the trial he was probably the most popular, if not the most powerful, man in Scotland. Marks of sympathy were showered on him from all sides.

In 1875 he was appointed one of the Old Testament Revisers; in 1880–82 he delivered by invitation, to very large audiences in Edinburgh and Glasgow, two courses of lectures on the criticism of the Old Testament, which he afterwards published (*The Old Testament in the Jewish Church*, first edition 1881, second edition 1892, and *The Prophets of Israel*, 1882, which also passed through two editions); and soon after his dismissal from his chair he joined Professor Baynes in the editorship of the *Encyclopædia Britannica*, and after Professor Baynes's death remained in supreme editorial control till the work was completed. His versatility, firmness combined with tact, width of view, and painstaking struggle for accuracy were largely responsible for the maintenance of its high standard. But he did not let his other duties interfere with his Semitic studies. He visited Arabia, Egypt, Syria, Palestine, Tunis, and southern Spain, and had an intimate knowledge of, and personal acquaintance with, not only the literature, but the life of the East. His early friendship with J. F. McLennan, that most original student of primitive marriage, had a great influence on Smith's studies, and his attention was always strongly attracted to the comparative study of primitive customs and their meaning. His chief contributions to this branch of learning were his article SACRIFICE in the *Encyclopædia Britannica*, his *Kinship and Marriage in Early Arabia* (Cambridge, 1885), and above all his *Lectures on the Religion of the Semites*, 1st edition 1889, 2nd edition 1894. His originality and grasp of mind enabled him to seize the essential among masses of details, and he had in a marked degree the power of carrying a subject further than his predecessors.

In 1883 Robertson Smith was appointed Lord Almoner's Professor of Arabic at Cambridge, which henceforth became his home. He occupied rooms in Trinity College till 1885, when he was elected to a professorial Fellowship at Christ's College. In 1886 he became University Librarian, and in 1889 Adams Professor of Arabic. In 1888–91 he delivered, as Burnett lecturer, three courses of lectures at Aberdeen on the primitive religion of the Semites, of which only one course has been published (see above). Early in 1890 grave symptoms of constitutional disease manifested themselves, and the last years of his life were full of suffering which he bore with the utmost courage and patience. He never ceased to work, and when near his end was actively engaged in planning the *Encyclopædia Biblica*, which he had hoped to edit. He died at Cambridge, 31st March 1894, and was buried at Keig. Small and slight in person and never robust in health, Robertson Smith was yet a man of ceaseless and fiery energy; of an intellect extraordinarily alert and quick, and as sagacious in practical matters as it was keen and piercing in speculation; of an erudition astonishing both in its range and in its readiness; of a temper susceptible of the highest enthusiasm for worthy ends, and able to inspire others with its own ardour; endowed with the warmest affections, and with the kindest and most generous disposition, but impatient of stupidity and ready to blaze out at whatever savoured of wrong and injustice. The sweetness and purity of his nature combined with his brilliant conversational powers to render him the most delightful of friends and companions. (A. E. S.)

Smolensk, a government of West Russia, lying to the east of Moscow, with an area of 21,638 square miles and a domiciled population which numbered 1,191,172 in 1882 and 1,551,068 in 1897, when there were 810,765 women and the urban population numbered 121,383. In 1898 the population was estimated at 1,671,000. It is chiefly composed of White Russians (47 per cent.), in the west, Great Russians (42 per cent.), in the east, and a mixture of both (11 per cent.). Most of the inhabitants (98 per cent.) belong to the Orthodox Greek Church; the rest are Nonconformists. The province is divided into 12 districts, the chief towns of which are Smolensk (see below), Byelyi (6956), Dorogobuzh (6640), Dukhovschina 3115), Elnya (2429), Gzhatsk (6312), Krasnyi (2755), Poryechie (5692), Roslavl (17,848), Sytchevka (4805), Vyazma (15,676), and Yukhnoff (2253). In 1899 there were 1492 schools, attended by 78,700 scholars, of whom only 15,400 were girls. Forty per cent. of the children of school age received no education at all. The county and district councils, however, are very active in organizing

hospitals and infirmaries, and all the peasants in the province are embodied in a mutual insurance against fire. Out of a total area of 13,687,000 acres 5,342,000 were held by the village communities, 7,172,000 by private persons, and 324,000 by the Crown. No less than 5,029,000 acres, or 37 per cent. of the total area, are under forests, and 1,215,000 are uncultivable. Nearly 30 per cent. of the surface is arable land, and 20 per cent. is under meadows. In the year 1900 there were 2,200,000 acres under crops, and the average yield in 1895–99 was: rye, 6,932,000 cwt.; wheat, 80,500 cwt.; oats, 4,260,000 cwt.; barley, 755,000 cwt.; all cereals, 12,104,000 cwt.; also potatoes, 7,473,000 cwt. This supply is not sufficient for the population, and grain has to be imported. Improved agricultural implements are beginning to be manufactured within the province, and to be applied on the landlords' estates, and partly also by the peasants. Flax (121,500 acres) and hemp are important crops, and some tobacco is also grown. There were in 1898, 438,000 horses, 564,844 horned cattle, 629,250 sheep, and 242,920 pigs in the province. In the way of mining industries only phosphorite is extracted, and of this, 32,000 cwt. is obtained annually. The domestic trades are not so well developed as in the other parts of Central Russia, while in 1898 there were only 1762 factories, employing 13,000 workers and showing a yearly return of about 14,000,000 roubles. The most important industry is that represented by a large paper mill, which employs no fewer than 4000 hands. A considerable part of the population is, however, compelled to leave their homes in search of work in different parts of Russia. (P. A. K.)

Smolensk, the capital of the above government, built on both banks of the Upper Dnieper, 260 miles by rail west-south-west of Moscow, at the junction of the two important railways from Warsaw to Moscow and Riga to Orel. The city has much improved of late years. It has monuments in remembrance of the war of 1812 and of the Russian composer Glinka. It is well provided with schools, and has three public libraries, a historical and archæological museum which contains very interesting antiquities, a people's palace and a people's theatre, and several philanthropic and scientific societies. It is well supplied with water, and has an extensive network of telephones. Factories and trade, however, are but feebly developed. Population (1897), 46,900.

Smyrna, *Ismir*, the capital of the Aidin vilayet, and the most important town of Asia Minor, situated at the head of a gulf 30 miles long, in 38° 26′ N. and 27° 9′ E. It is one of the principal ports of the Ottoman empire, and has a large trade, of which the greater part is with Great Britain. The total values of the general trade for 1898, 1899, and 1900 were:—

Year.	Exports.	Imports.
1898 . .	£3,294,529	£2,677,948
1899 . .	3,782,781	2,562,885
1900 . .	2,541,172	1,425,480

Earlier returns are not very trustworthy. The chief items of export are figs, tobacco, valonea, carpets, raisins, and silk. The British share of the total trade amounted in 1899 to 50 per cent., and in 1900 to 57 per cent. In 1900 the appearance of plague, and the consequent imposition of quarantine by Turkish and foreign ports upon all arrivals from Smyrna, paralysed trade. Until 1894 the two railways from Smyrna to the interior belonged to British companies, but in 1897 the Smyrna–Ala-shehr line passed into the hands of a French syndicate, which completed an extension to Afiún Kara-hissar, and so effected a junction with the Anatolian railway system. The Smyrna–Aidin line has been extended to Dineir. The population is about 250,000, of whom more than half are Greek, including 45,000 Hellenic subjects, and less than one-fourth Moslems. The Moslems, Armenians, Greeks, Europeans, and Jews live in separate quarters of the city. Interesting discoveries throwing light on the water-supply of Roman Smyrna have been made.

Smyth, Charles Piazzi (1819–1900), British astronomer, was born at Naples on the 3rd January 1819. He was called Piazzi after his godfather, the celebrated Italian astronomer of that name, whose acquaintance his father, Admiral Smyth, had made at Palermo when on the Mediterranean station. His father subsequently settled at Bedford, where he erected the well-known Bedford Observatory, at which Piazzi Smyth received his first lessons in astronomy. At the age of sixteen he went out as assistant to Maclear at the Cape of Good Hope Observatory, where he soon distinguished himself by his observations and drawings of Halley's comet and of the great comet of 1843; also taking an active part in the verification and extension of La Caille's arc of the meridian and the measurement of the Zwartland Base. In 1845 he was appointed astronomer royal for Scotland and professor of astronomy in the University of Edinburgh in succession to Henderson. On assuming this post his first task was to complete the reduction of the observations made by his predecessor (see *Edinburgh Observations*, vols. xiv. and xv.). In 1856 he undertook an interesting experiment to test the advantages of a mountain station for astronomical observations, selecting for this purpose the Peak of Teneriffe, as being situated in a low latitude and fairly easy of ascent. The Admiralty made him a grant of £500 for the purpose of this mission, and a yacht—the *Titania*—of 140 tons and a fine 7½-inch equatorial telescope were placed at his disposal by friends. The first station occupied was at a height of 8900 feet on the southern wall of the crater of elevation, the 7½-inch telescope being afterwards erected at Alta Vista, 10,700 feet above the sea-level. The principal result of the astronomical observations made at these great heights was to verify Newton's surmise, that a "most serene and quiet air . . . may perhaps be found on the tops of the highest mountains above the grosser clouds," a discovery subsequently turned to splendid account at the American mountain observatories of Mount Hamilton, in California, and Arequipa, in Peru. Accounts of the results of this expedition, including measures of the radiation of heat from the moon, observations of the solar spectrum, and of the meteorological characteristics, are contained in the "Report on the Teneriffe Astronomical Experiment of 1856, addressed to the Lords Commissioners of the Admiralty, 1858," in the *Phil. Trans.* of the *Roy. Soc.* of the same year, and the *Edinburgh Observations*, vol. xii. A more popular account of the expedition will be found in *Teneriffe, an Astronomer's Experiment: or, Specialities of a Residence above the Clouds*, 1858. About 1874 Piazzi Smyth began to study the spectra of luminous gases, of the rainband, the aurora, and zodiacal light. In 1877 he went to Portugal to observe the solar spectrum under more favourable conditions than was possible in the atmosphere of Edinburgh, and was eminently successful in resolving into their constituent lines the broad bands at the red end of the spectrum. For these results, published in the *Trans. R. S. Ed.* vol. xxix., he received the Macdougall-Brisbane prize in 1880. Accounts of later spectroscopic researches are published in *Madeira Spectroscopic* (1882) and in the *Trans. R. S. Ed.* vol. xxxii. Pt. ii. He also carried out in the laboratory an extensive

investigation on the spectra of gases, and in conjunction with Professor A. S. Herschel discovered a remarkable relation connecting the chief lines of carbonic oxide. Amongst his other published works may be mentioned *Three Cities in Russia* (1862), *Our Inheritance in the Great Pyramid*, *Life and Work at the Great Pyramid*, and a volume *On the Antiquity of Intellectual Man, from a Practical and Astronomical Point of View*. In 1888 he resigned his professorship and the post of astronomer royal of Scotland, and retired to the neighbourhood of Ripon, where he died on 21st February 1900. (A. A. R*.)

Sneek, a town in the Dutch province of Friesland, to the west of Sneek Lake, 12 miles south-south-west of Leeuwarden. It is connected by steam tramways with Heerenveen and Harlingen, and a railway to Stavoren was opened in 1885. There is an industrial school and a school for teachers. Population (1900), 12,100.

Sniatyn, the chief town of a district in Galicia, Austria, on the left bank of the Pruth, near the frontier of Bukovina, with important horse and cattle fairs and tanning. Population (1890), 10,939; (1900), 11,498.

Snoilsky, Carl Johan Gustaf, COUNT (1841———), Swedish poet, was born at Stockholm on 8th September 1841. He was educated at the Clara School, and in 1860 became a student at Upsala. He was trained for diplomacy, which he quitted for work at the Swedish Foreign Office. As early as 1861, under the pseudonym of "Sven Tröst," he began to print poems, and he soon became the centre of the brilliant literary society of the capital. In 1862 he published a collection of lyrics called *Orchids*. During 1864 and 1865 he was in Madrid and Paris on diplomatic missions. It was in 1869, when he first collected his poems under his own name, that Snoilsky took rank among the most eminent contemporary poets. His *Sonnets* in 1871 increased his reputation. Then, for many years, Snoilsky seemed to have entirely abandoned the art of poetry, and to have devoted himself to the work of the Foreign Office and to the study of numismatics. In 1876, however, he published a translation of the *Ballads* of Goethe. In 1879 Snoilsky's life underwent a violent crisis, which was the subject of infinite gossip in Sweden. He had risen to the highest distinctions in official life; he had in 1876 been appointed keeper of the records, and he had succeeded Bishop Genberg as one of the eighteen of the Swedish Academy. He resigned all his posts, and left Sweden abruptly in company with the Baroness Ruuth-Piper, whom he married in 1880. In his exile, Count Snoilsky turned again to poetry, and sent home in 1881 a volume of *New Poems*. *Savonarola* followed in 1883, and *The White Lady* in 1885. This period of activity also came to an end with the publication of a collection of *Poems* in 1887, and during later years Count Snoilsky contributed little to current literature. Since 1891 he has been principal librarian of the Royal Library in Stockholm. His influence, however, continues to be great; his verses are read with eagerness by the old and the young alike. He has always sung of joy and liberty and beauty, of the greenness of spring and the glory of the morning, and in his lyrics, more than in most modern verse, the ecstasy of youth finds its due expression. He is remarkable, also, for the extreme delicacy and melodiousness of his verse-forms, for he is essentially and almost exclusively a lyrical poet.

Snowdon (Welsh, *Eryri*), a mountain in North Wales. It is built up of slates, grits, and porphyries belonging to the Cambrian and Silurian systems, and consists of five ribs, meeting together at the summit (Y Wyddfa), 3560 feet above sea-level, and embracing between them steeply scarped depressions or vast precipitous hollows, of which the best known are Cwm-Glas on the north and Cwm-y-Llan on the south. Snowdon lies far below the snow-line, and is indeed, as a rule, quite free from snow between April and October. The mountain is encircled by a cluster of similar peaks, 1500 to 500 feet lower in altitude. Between it and them there is, however, a girdle of glens or passes, which present much wild and striking scenery. Of these the most notable is the Pass of Llanberis, which skirts the north-east foot of Snowdon, and is steep and narrow, being shut in on both sides by bare mountain slopes. It disputes with the Pass of Aberglaslyn, which proceeds due south from Beddgellert, at the south foot of Snowdon, the supremacy as the wildest pass in this part of Wales. The two passes are connected by the Nant-Gwynant defile, which skirts the south-east foot of the mountain. Along the south-west foot runs the glen of Nant-Colwyn, which is continued to Carnarvon, 12 miles north-west from Beddgellert. The summit of Snowdon is frequently shrouded in mist, of which good imaginative use is made in Mr Watts-Dunton's novel of *Aylwin*. Since 1897 it has been ascended by a rack-and-pinion railway, 4¾ miles long, which starts at Llanberis, at the north-west foot of the mountain, and terminates at the hotel which crowns the top. One of the charms of Snowdon is its lakes, of which there are two at Llanberis; one on the east side, filling the bottom of the hollow between the Crib-goch and Lliwedd ridges; a couple in the Nant-Gwynant defile; and another at the western foot of the mountain. Close to Llanberis the primitive beauties of the scenery are sadly impaired by the extensive slate quarries of Dinorwic, which employ some 2000 men. This region is naturally the resort of crowds of holiday-makers during the warmer months of summer. The most popular centres within the district itself are Llanberis, Beddgellert, Pen-y-Gwryd, and, a little farther away, Capel-Curig—the last two on the east side of the mountain; while convenient centres outside the immediate district are Carnarvon, Bangor, Bettws-y-Coed, and even Llandudno. The minor attractions of the region embrace Dolbadarn Castle, which figured in the Anglo-Welsh wars of the 13th and early 15th centuries, and the falls of Ceunant Mawr, both near Llanberis; and the church and the reputed tomb of Llewelyn's famous hound at Beddgellert.

SOCIALISM.

FOR the purposes of modern discussion, Socialism may be described as that policy which aims at a more equal distribution and, in subordination thereto, a better production of wealth by means of the direct action of the central authority. It is thus distinguished (*a*) from the policy of *laissez-faire*, or least-possible interference with the competition of private persons or groups of persons among themselves, and (*b*) from the policy of Regulation, where the central authority deliberately watches and controls the action of industrial competitors, but avoids direct initiative in production and direct attempts to level inequalities of wealth. The leading idea of the Socialist is to convert into a general benefit what is now the private gain of one or a

General description.

few. He shares this idea with such reformers as the Anarchist, the Positivist, and the Co-operator; but, unlike them, to secure his end he would employ the compulsory powers of the State or the municipality. Where the public direction or diversion of industry is mainly for the benefit of a few, as in the protective system of some countries, this is hardly Socialism. It employs the same machinery, the compulsory powers of the central authority; and it secures a revenue which may or may not be for the general benefit; but so far as the "protection" is successful, the main result is the private gain of a few, whereas Socialism would secure the main benefit for society as a whole. Communism has the same aim as Socialism and the terms are often used convertibly. But the Communist need not be a Socialist or the Socialist a Communist. The Socialists of the beginning of the 20th century rarely demand that all wealth shall be held in common, but only that the large workshops, and the land, and the materials and means of production on a large scale, shall be owned by the State or municipality.

The Socialism of this period has in fact a quality of its own. It is founded on a more or less clearly understood economic theory, and therefore is frequently described as Economic or Scientific Socialism. It may be true that in the first instance men become Socialists not from logic but from observation of suffering and from sympathy with the sufferers. But the Socialism of our own time, without disowning sentiment, is better aware than its predecessors of the need of facts and arguments for the persuasion of the public. It is significant, in this connexion, that, while all over the civilized world there is evidence that the volume of suffering has since the 'seventies grown somewhat less, the influence of Socialism has grown somewhat more. Nowhere is this more true than in Germany, the birthplace and stronghold of the new doctrines.

Germany.

The earlier history of Socialism in Germany has been already given with sufficient fulness (*Ency. Brit.* 9th edition, vol. xxii., SOCIALISM); and the briefest reference to the chief common doctrines of the school may be made here. From the study of Hegel, both Marx and Lassalle had been impressed with the idea of Evolution; they had learned that the world of men, like the world of things, was in constant process of development; but, unlike Hegel, they conceived the evolution as purely materialistic; the progress of civilization was effected by a struggle between classes in society for material wealth and well-being. Feudalism, itself the result of such a struggle, had given place to the rule of the middle classes (*bourgeoisie*), and the struggle is now between the privileged capitalists and the disinherited working men. At present those who do not possess capital are so placed that they must work for such wages as will keep them alive, and the gains from invention and industrial economies fall to the employers and the capitalists generally. Because of the helplessness of the labourer, he is forced (*a*) to work at his cost price (or the bare necessaries of civilized life), but (*b*) to produce much more than his cost, the surplus going to his employer. This is what Lassalle called the Brazen Law of Wages, founded on Ricardo's supposed doctrine that the value of an article produced under conditions of competition is determined by its cost in labour, and that the wages of labour tend to equal the labourer's subsistence. Without labour, capital cannot utilize its advantages, and the tendency of the labouring population to increase beyond the means of their constant employment is a frequent benefit to the capitalists in the periodic expansions of investment and enterprise arising in response to new inventions and new discoveries. Large businesses swallow up small; not only independent artisans and the workers in domestic industries, but small capitalists, who cannot afford the economies and low prices of their larger rivals, are disappearing. But the growth of the proletariate, together with the concentration of all business in fewer hands, will accomplish the downfall of the present system of industry. The proletariate will realize their own strength; and the means and materials of production will be concentrated one degree more, namely, in the hands of the commonwealth for the good of all. This revolution, like that which overturned feudalism, is simply the next stage in an evolution that will happen without human will, fatally and necessarily, in virtue of the conditions under which wealth is produced and shared in our times.

Such was in substance the view of all the leading German Socialists of the last half of the 19th century. Rodbertus alone practised as well as preached the belief that "the social question was a purely economic question," and confined himself to his study; but even he was not content with a mere statement of the fact of evolution—he advanced, like the rest, a claim of right on behalf of working men. The others went further. They made "the social question" a question of politics. Marx and Engels from the days of the French Revolution of 1848 had appealed to the "proletariate of all countries" to unite to hasten the day of their emancipation. Marx founded the International Association of Working Men in the year of Lassalle's death (1864). Lassalle's Socialism was meant for Germany first. He had planned a centralized organization of workmen led by a dictator. He had called on the Government to establish from the funds of the State co-operative associations such as Schultze-Delitzsch had hoped to plant by "self-help." Lassalle's Socialism was rather national than international. But before the common danger of police prosecution his followers united with the followers of Marx at the Congress of Gotha in 1875. The name Social Democrats crept into use about 1869, when the followers of Marx founded, at a Congress at Eisenach, "the Social Democratic Working Men's Party." The party began to be a power in Germany about the year 1875. It is a power now; but the doctrines and policy of the party have undergone some change.

The last quarter of the 19th century witnessed (1) the repressive laws of 1878, (2) the repeal of them in 1890, (3) the three Acts of Insurance, and, above all, (4) the progress of German industry and wealth. After the occurrence of two attempts (in 1877) on the life of the aged Emperor William, Bismarck's Government, already alarmed by the increased number of votes given to Socialist candidates for the Reichstag, procured the passing in October 1878 of the "Exceptional Powers Act" (*Ausnahme-Gesetz*). The legislation of 1878 resembled in its purpose and effects the Six Acts of 1819 in England. Combined action in Germany became almost impossible, and for organs of the press the Social Democrats had recourse to Zürich. Liebknecht and Bebel could still raise their voice for them in Parliament, for Bismarck's attempts to deprive members of the Reichstag of their immunities was foiled (March 1879). But the agitation as a whole was driven underground; and it speaks well for the steady patience and self-control of the German people that no widespread excesses followed. The declaration of the Social Democratic Congress at Wyden, Switzerland, in 1880, that their aims should be furthered "by every means" instead of, as formerly, "by every lawful means," was a natural rejoinder to the law that deprived them of the lawful means; and it seems to have had no evil consequences. After twelve years, repression was so far relaxed that (in 1881) workmen's trade unions were allowed to recover legal standing. In 1890 the Reichstag refused to

renew for a fifth period the obnoxious law of 1878; and finally, in 1899, the Reichstag repealed the law forbidding amalgamation of workmen's trade unions and specially aimed at the new socialistic unions, the natural allies of the Social Democrats. It might thus seem that the party was never so powerful as at the opening of the 20th century. Since 1890 the vexatious prosecutions and condemnations for *lèse majesté* have done the cause more good than harm. In 1878 the Socialists polled 437,438 votes for the Reichstag; in 1881, 311,961; in 1884, 549,990; in 1887, 774,128; in 1890, 1,427,000; in 1894, 1,800,000; in 1898, 2,120,000; and the number of their representatives increased from 12 in 1877, 37 in 1890, 46 in 1894, to 56 in 1898.

This increase of Socialism in Germany is the more remarkable because of the remedial measures, intended to forestall Socialism, that had been passed in the interval between 1878 and 1890. Bismarck, as he himself allowed in the debates of 1878 (6th September), had known and admired Lassalle, and he had none of the scruples of abstract theorists against the intervention of the State. Accordingly, he planned the series of measures for the insurance of workmen against sickness, accidents, and old age, which became law, in 1883, 1884, and 1891 respectively. The Socialists at first sneered at these measures, and then accepted them. They not very unreasonably regarded the Government as their convert. They could also point to at least two other unwilling witnesses — the Christian Socialists and the Socialists of the Chair (*Kathedersocialisten*).

In Protestant parts of Germany the Socialists as a rule were Social Democrats. In the Catholic parts the following of the Social Democrats was more scanty; but Socialist sentiment and doctrine were represented as early as 1863 and 1864 by Dr Döllinger and Bishop Ketteler, followed by Canon Moufang. Ketteler, who had been under the influence of Lassalle, thought of inducing the Church to make productive associations her special care. Moufang would depend more on the State than on the Church. All were awake to the evils of the workmen's position as described by the Socialists of the ordinary type, and they were anxious that the Catholic Church should not leave the work of curing those evils to be done without her sympathy and aid. Ketteler died in 1877; and the Pope's Encyclical of 28th December 1878 bore no trace of his influence, mixing up as it did Socialists, Nihilists, and Communists in one common condemnation. The Encyclical *De conditione opificum* of 1891 showed that the views of the Catholic Socialists had penetrated to headquarters; but the Encyclical on *Christian Democracy* (January 1901) betrayed no sympathy with them. The Protestant Church in Germany has been hampered by fear of offending the Government. But it contains a vigorous, if tiny, body of Christian Socialists. Rudolf Todt, a country pastor, was the prophet of their movement; his book on *Radical German Socialism and Christian Society*, written in 1878, led Dr Stöcker, the Court chaplain, to found an organization for "Social Reform on Christian Principles." This was denounced rather unfairly by politicians of all ranks, Socialist and otherwise, as an organized hypocrisy. For whatever reason, its influence was shortlived, and its successor, the Social Monarchical Union (1890), shared in the unpopularity of Stöcker, its founder. Even the Socialists of the Chair, middle-class Protestants as they often were, would have nothing to say to it, but preferred to go a way of their own.

There had existed in Germany since 1858 a league of economists and statesmen called the "Economic Congress" (*Volkswirthschaftlicher Congress*), bearing a general resemblance to the Cobden Club, though its chief object was to bring about free trade among German states in particular. After the Empire, its work seemed finished; and some statesmen and economists formed a new society, the "Union for a Policy of Social Reform" (*Verein für Socialpolitik*). Professors Schmoller, Roscher, Hildebrand, Wagner, Brentano, the statistician Engel, and others met at Halle in June 1872, and a meeting of their supporters was held at Eisenach in October of that year. These academic Socialists, or Socialists of the Chair, agreed with the ordinary Socialists in recognizing the existence of the "social question," the problem of how to make the labourer's bad condition better. The orthodox economists saw no problem there for legislation; competition was supposed to solve its own problems. But, while the ordinary Socialists looked for Social Revolution, the academic Socialists were content to strive after Social Reform on the basis of the existing system of private property and rights. This social reform, however, was to be actively furthered by the State, without regard to the scruples of the Manchester School. The State was regarded as a "great moral institution for the education of the race." Bismarck is said to have declared in 1875 that if he only had time he, too, would join the union. It was, in fact, a union of moderate State Socialists, Socialists who relied on the State, and the State as it then was, for social reform. The Government Insurance Acts owed not a little to the labours of these men, who gave their services freely for the necessary preliminary investigations. The union, as a rule, met once in two years at some German town.

The German people have been prepared for State Socialism by the efficiency of the German bureaucratic Government, made so manifest in the wars of 1866 and 1870. If the insurance laws are successfully carried out, the confidence of the people in the Government, and in the State as it is, may be so strongly confirmed as to put any idea of a complete revolution out of their thoughts. It can hardly be said that this idea is absent now; but the attitude of the Social Democratic party is at least less uncompromising than it was in the beginning. Since they regained their liberty in 1890, they have been well kept in hand by their leaders. Their journal, *Vorwärts*, is conducted with remarkable ability. Their agitation has been as peaceful as that of trade unionists or co-operators in England. They have ceased to denounce the Churches. They have tried to gain converts and sympathizers by showing themselves ready to take up the cause of any specially distressed class of workers, and press their special claims on the State. From a necessary evil or mere stop-gap, the present State has become to them gradually, and perhaps unconsciously, their own State. The Anarchists had been disowned and expelled as early as 1880. The Socialists who demanded return to the old uncompromising tactics, were cast out at Erfurt in 1891, and exist as "Independent" Socialists. The controversies between the advocates and the opponents of Socialism still go on in learned circles, and produce a prodigious quantity of literature year by year; but the Social Democracy, which Schäffle the academic Socialist regarded in 1885 as "without prospects," would deserve less severe treatment now than it received from him then. Though the programme adopted at Gotha in 1875 stands almost unaltered, the parts due to Lassalle have fallen into the background. For many years Marx has been the chief economic authority of the party. Marx died in 1883, but remained an oracle till 1894 when (just before his own death in 1895) Engels published the last volume of his friend's book on "Capital." This volume was expected to solve certain serious logical difficulties in the

system; and instead of this it caused a feeling of disappointment, which can be traced even in the *Neue Zeit*, the literary and scientific organ of the party, as the *Vorwärts* is the popular. Many, like Bebel and Kautsky, keep up the old adoration of Marx; but the younger, like Bernstein, have rightly felt that to give up Marx is not to give up Socialism, any more than to give up Genesis is to give up theology. Bernstein has openly proposed in Congress that the old doctrines and policy of the party, involving as they do despair of Reform and insistence on Revolution, shall now be dropped. Though he has not yet carried his point, his opponents have not succeeded in expelling him from the party. The death of Liebknecht (August 1900) removed not only an almost heroic figure from the ranks of the Social Democrats, but an old-fashioned Socialist who was a serious obstacle to any change of front. Yet Liebknecht himself, though he once thundered against the Bavarian von Vollmar for proposing a truce (1891), had latterly been drifting in this very direction. It was impossible for a man of his practical wisdom to close his eyes to what the State had done for the German workman. It was also impossible to ignore the great progress that Germany had made in wealth and industry since the creation of the Empire in 1871. Germany has been fast becoming a manufacturing instead of a merely agricultural country; and, though the rise of large manufacturing towns in the Rhine valley and elsewhere has multiplied Socialists, whose numbers are chiefly recruited from the towns, it has added to the income of the ordinary German workman. He is farther from poverty and distress than he was a generation ago; and his Socialism is an endeavour after a larger life, not, as formerly, a mere struggle against starvation. It is likely, therefore, to have less and less of mere blindness and violence in it.

The condition and prospects of the working man in Germany are fast becoming those that have prevailed in England since the repeal of the Corn Laws in 1846. They fall far short of perfection, but also of hopelessness. The German Corn Laws must pass away like the English, and for the same reasons. In 1902 the Social Democrats threw their weight on the side of repeal.

Great Britain.

England, which sheltered Marx and Engels, has never itself been a soil very favourable to Socialism; but in the last quarter of the 19th century, in the poorer districts of our large towns, the Secularism of, say, 1875, has been supplanted by Socialism. Certainly among all classes there are more Socialists in England now than formerly; and it is more easy to say when than why the change has occurred. In 1879 Mill's essays on Socialism were published. The writings of Henry George (1880) and his lecturing tour (1881–82) in Great Britain revived interest in the claim for the nationalizing of the land, a form of Socialism endemic in England for more than a hundred years. It had been taught by Thomas Spence (1775), James Mill (1821), Dove (1850), Herbert Spencer (1851), and A. R. Wallace (1882). The Irish Land League included advocates of it; but Gladstone's Land Act of 1881, though it was an interference with private bargaining and in many ways approached Socialism, settled the main question of ownership entirely in an individualistic sense. The English Land Restoration League makes way very slowly. Socialists pointed out that George's single tax on rents was illogical; he would take away all the surplus value secured by the landlord, but would leave all the surplus value secured by the employer and capitalist. The more logical Socialists had formed, in 1880, the Democratic (called afterwards, in 1883, the Social Democratic) Federation, of which the two principal leaders were William Morris, "poet and paper-hanger," and H. M. Hyndman, journalist and stockbroker. Its weekly organ, *Justice*, is still published. In 1884 William Morris seceded, and with Aveling (son-in-law of Marx) and Mr Belfort Bax established the Socialist League, with its organ, *The Commonweal*. Morris abandoned the League in 1890, though he held to the end, if somewhat vaguely, his belief in Socialism. Bellamy's book, *Looking Backward* (1888), made some impression in England; and a greater was produced by *Merrie England*, written in 1894 by Thomas Blatchford, editor of a Socialist newspaper, the *Clarion*. But there was still no sign of a strong party such as we have found in Germany. Socialists in England have been forced to adopt the ordinary English methods for the redress of grievances, finding their best opportunities, very naturally, in times of a general depression in trade (as in 1887). Nevertheless a change has come over the spirit of politics in England, in the direction they desire, though hardly through any efforts of theirs. It is the change deplored by Herbert Spencer in his *Man versus the State* (1885), though it is neither sudden nor wonderful, but, in the light of events, inevitable. The period had passed when extension of the suffrage and free trade, and, generally, the removal of obstacles, could be considered panaceas. There was now a general feeling, seldom expressed in formulas, that there should be secured to all citizens the conditions under which a civilized life was possible. Hence there was a demand for greater stringency of Factory Acts and their administration. Increased attention was paid to elementary education and sanitary requirements. It is significant that the movement in favour of the better housing of the poor began in a speech of John Bright, an individualist of the old school (Glasgow, 1884). Sir William Harcourt said (1888), "We are all Socialists now," when he really meant that we were all social reformers, who would use the help of Parliament without scruple. The English people have neither set themselves against Socialism nor pronounced in its favour. Except in the solitary case of free trade in foreign imports, they are indifferent to general principles, and pride themselves on judging each case on its merits, as if no general principle affected the merits.

The English poor law is frankly socialistic; but the amount of its Socialism varies according to the administration of it in the several localities. In this matter the English have all been Socialists since the Act of Elizabeth, and have not gone either backwards or forwards on purely logical grounds. Of recent years the State has taken more care than formerly to preserve common lands. No general scruples have prevented interference with individual freedom in the matter of education (1870), vaccination, the labour of children and young persons in factories and workshops, the regulation of railways, the compensation of workmen for injuries (1897), to say nothing of sanitary requirements. Little of all this is socialistic in the strictest sense of the word. The workmen's compensation is not out of public funds. Where education is "free," or grants are made "in aid of rates," or the income tax and death duties are progressive, there is, perhaps, such an inroad on the revenue of one class for a real or supposed general benefit as would justify the term. But regulation, not initiative, is still the prevailing feature of the proceedings of the State in Great Britain. The railways are still in private hands. The Post Office, the telegraphs, the Post Office Savings Banks, are a group by themselves, and the first, at least, existed before there was any thought of Socialism.

The lesser central authorities have been much more inclined to conduct business for themselves. The supply of gas, water, and (more recently) electric light, the maintenance of docks and tramways, the acquisition not only of parks but of house property — all these symptoms of

municipal Socialism, some of them a generation or more old, have increased and multiplied in recent years, and perhaps most conspicuously in towns (like Glasgow, Birmingham, Bristol, Manchester, Liverpool, Leeds, Bradford, Huddersfield) where political Socialism has feeblest hold.[1] The passing of the Local Government Acts (1888, 1894), and the new interest aroused in municipal politics, throughout London in particular, by the establishment of its County Council and Borough Councils, may seem to have provided ready tools for municipal Socialism. But the actual achievements of London have certainly not surpassed those of the provincial cities, except in greatness of scale. It is the demand persistently made for permission to tax ground-rents and "unearned increment" that points to State Socialism, for such permission must sooner or later lead to State taxes of the kind described.

Public men and journalists deplore or defend the extension of municipal trading; meanwhile the trading goes quietly on, with the connivance of the classes most likely to suffer from a really socialistic or levelling policy. It may be that the middle classes have learned from Ruskin and Tolstoy some sympathy for the aims of Socialism; and a few of them have become avowed converts. Anarchist colonies have been founded at Purleigh, Essex (1897), and at Sheepscombe, Gloucester, on the principles of Tolstoy. A band of Christian Socialists has gathered together, and news of foreign agitations (as of Bellamy and Henry George) and colonial experiments has not been without interest; but the strongest movements in England are still such as Lassalle ridiculed as "self-help." English public opinion was sceptical when the Trades Union Congresses declared themselves powerless to establish an eight hours' working day without the help of the State (*e.g.*, Congresses of 1891, 1892). Resolutions in favour of the nationalizing of the land and of the other means of production have been passed at most of the meetings since 1888, first on the ground that only by these means could the unemployed be effectually helped, afterwards for more general reasons. The programme proposed on such occasions is always bolder than the policy eventually adopted. Mr John Burns, for example, said at Cardiff in 1895: "The Eight Hours Bill, the Miners' Eight Hours Bill, the Railway Hours Act (which had given employment to 10,000 men), higher wages and eight hours for Government workmen—all these things were in the direction of helping the unemployed. . . . He had endeavoured to get the immediately possible, and in doing so he believed he was bringing about the social revolution."

The agitation on behalf of the unemployed had led to disturbances in London in February 1886 and November 1887. With the return of brisk trade the problem departed for the time. Depression is always the Socialists' best opportunity. They can hope to impress their views on the unemployed masses, and profit by the fear of the trade unionists that the competition of the unemployed will endanger the position of the trades societies. In the last quarter of the 19th century a new unionism grew up. It is less aristocratic than the old, aiming at the inclusion of the comparatively unskilled labourers (as the dock labourers, formed into a union in London in 1889); and it seeks the federation of all trades societies, with a view to joint action. Moreover, within the separate unions the old government by mass meetings of all the members has given place to a government by representatives, and administration by permanent paid officials. This seems to lead not to democracy, but to bureaucracy; but it serves as some preparation for the Democratic Socialism held out by some of the leaders as the ideal. A better preparation, because in the way of actual business, is given by the co-operative societies, whose members are nearly as numerous as those of the trades societies, and more especially by the co-partnerships of Leicester and Northampton, &c. But these last are a very small body; and even the trade unions had in 1898 only about 1,644,000 members, or about one-eighth of the estimated number of the working classes. A decision of the highest Court (in the case of the Taff Vale Railway Co. *v.* The Amalgamated Society of Railway Servants, 1901) gave to the trade unions, in place of the privileges of a club, the liability of a corporation to be sued as a whole. The financial dangers of this position are fully understood by trade unionists. The ultimate results cannot be foreseen. The immediate effect is to drive the men into more earnest political action.

Attempts had been made to influence politics directly by means of an Independent Labour Party (founded at Bradford in January 1893 by Mr Keir Hardie), which bound itself to support only candidates of sound socialistic views. This was a sectional effort, which, except in municipal politics, had scant success. In municipal politics, again, especially in London, the Fabian Society, founded in 1884 by a group of young literary men, had exercised some influence; but, if we compare the "Fabian Essays" of 1889 with the later utterances of their writers, it becomes clear that these Socialists have become for the most part hearty Radical politicians, energetic in municipal work beyond their fellows, but hardly otherwise to be distinguished from them. They "do not suggest that the State should monopolize industry, as against private enterprise or individual initiative, further than may be necessary to make the livelihood of the people and their access to the sources of production completely independent of both" (*Fabian Tracts*, No. 70, 1896). The reservation is wide; but fortunately it is added: "they accept the conditions imposed by human nature, and by the national character and political circumstances of the English people." The course of events has reconciled Socialism with political reform. In Germany itself (at the Congress held at Mainz in September 1900), the proposal of Bebel, that Democrats be allowed on occasion to ally themselves with ordinary political parties, was accepted, under qualifications that are likely to disappear.

France.

Marx said that nothing great could be done even in Germany for revolution without the aid of England. But he had also said that there must be "the crowing of the Gallic cock." French passion is as indispensable as German reason. The enthusiasm for revolution is rather latent than wanting in France. The country population, with their small properties, will not favour revolution; but the working classes in the large towns are almost to a man Socialists or Anarchists in sentiment. They lack only opportunity and organization to be formidable. Something like a general movement towards organized Socialism began, on the return of some prominent leaders of the Commune of 1871 from exile. A Congress was held at Havre in 1880, which, under the leadership of Guesde and Ferroul, adopted a Social Democratic or "Collectivist" programme. In the following years a minority of the party, under Brousse and Joffrin, broke away from the main body and stood out for municipal Socialism, decentralization, and (in 1887) "self-governing workshops" aided by public money. Co-operative workshops are already helped

[1] The subject of municipal ownership and municipal enterprise has come more and more to the front in England in late years. Curiously enough, in the United States the opposite tendency was shown, the experience of a preceding generation having caused a reaction. Reference should be made to Sir Henry Fowler's paper on "Municipal Finance" (*Journal of Statistical Society*, vol. lxiii., 1900), and to the remarkable series of articles in *The Times* on "Municipal Socialism," which appeared during the autumn of 1902.

forward in France by public funds, preferences in public works, and other privileges, without striking results. The *Broussistes* are also called *Possibilistes*, content with such Socialism as is immediately practicable. They support, for example, agrarian reform on the present basis of private property (Marseilles, 1892). After several unsuccessful attempts, the amalgamation of the Collectivists, Possibilists, and Extreme Revolutionaries (*Blanquistes*) was accomplished in 1899. But this body has not the cohesion of the German party. Though the Socialists in the French Chamber act more or less loyally together, they are not so directly under the orders of the organization outside. M. Millerand's acceptance of the ministry of commerce caused some misgivings among his fellow Socialists (Congress at Paris, September 1900). The *Revue Socialiste*, founded by Malon in 1893, has not the same standing as the German *Vorwärts*. The wayward guerilla warfare of the French Socialists is a contrast to the disciplined strategy of the Germans, perhaps because political liberty is greater in France. The intervention of the French Socialists at Carmaux (Toulouse) in the dispute between the Glass Company and the workers was ill-managed (August to October 1892), and we may contrast with it the part taken by Socialist leaders in stopping riots in Berlin (February 1892).

In France the State has been always more ready than in England to interfere with the course of competitive trade, and to take the initiative on itself. Besides having control of the Bank of France, it owns most of the railways, administering them with tolerable success. It controls secondary as well as primary education. After the disturbances at Carmaux, it proposed to take over the mines. There is still no general poor law; and old age pensions are not yet fully organized, though they are on the way, and workmen's compensation has already come (1888). State Socialism would probably have gone farther if the French bureaucracy had not proved less efficient than the German. There is little academic Socialism. The bulk of French economists stand somewhat stiffly by the economic policy of J. B. Say; but men like Laveleye (who died in 1892), Gide among the younger economists, and the School of Le Play, at least acknowledged the existence of a "social question." There are also literary men of economic training (like Naquet) who advocate mild forms of Socialism. But the "Gallic cock" is not likely to crow at the bidding of Germany.

German Social Democracy found easier access to Belgium and Holland, and these countries have been a favourite meeting-place for Congresses of all denominations of Socialists. Crowded manufacturing Belgium had in 1876 two socialistic parties—the Flemish, led by Dr de Paepe, an ardent disciple of Marx, and the Brabantine or Walloon. They united in 1879, and helped the Liberals in 1893 to procure a much wider suffrage. The flourishing co-operative societies, the *Vooruit* in Ghent, and the *Maison du Peuple* of the Brussels bakers, are the work of their members. The Belgian Professor Colins has been an eloquent advocate of the nationalizing of the land. Belgium adopted Old Age Pensions for the Poor in 1900.

Belgium. Holland. Switzerland.

In Holland, which is still an agricultural and pastoral country, Socialism has not a strong foothold, though the Socialist leader Nieuwenhuis succeeded (1889) in bringing his party into line with German Social Democracy. The Dutch are active social reformers. They have had a Factory Act since 1889, and they passed an Act for Insurance of Workmen against Accidents in 1900. Reform is preferred to revolution.

Switzerland, for generations a refuge of exiles, usually shows them hospitality without sharing their views. The Confederation has not gone so far as compulsory insurance against sickness and accident (rejected on Referendum, May 1900), but it has a legal working day (of 11 hours). There is most Socialism in the German cantons. Scandinavia stands apart by its situation. In Denmark, especially in Copenhagen, German Socialism has had some influence. The trade unions are largely socialistic, and some converts have been made among the farm labourers. Denmark, in turn, has influenced Norway and Sweden, the latter with greater success than the former. But in neither is Social Democracy a political power.

Where, then, are we to look for the spread of the Social Democratic gospel? In Austria it has taken root among the German population, quietly and in face of severe measures of repression. In the Reichsrath of 1897 the party secured 12 out of 353 elected members. But if it had conquered all German Austria, there would still be Hungary and Bohemia to overcome; and political disunion tells against it.

If it is true that where there is poverty there will be Socialism, no country should be more socialistic than Italy, which has been described as "all proletariate." But the very wretchedness and ignorance of the masses, both on the land and in the cities, fitted them better for Anarchism than Socialism. Since 1882 there has been a Social Democratic organization, which has gradually drawn into itself the previously existing socialistic bodies. It was founded by Andrea Costa, and its most notable men now are perhaps Turati and De Amicis. In spite of the Government and the Anarchists, it has fought a good fight for the extension of the suffrage. In 1895 it returned 15 members to the Italian Parliament. Milan has been the real capital of the movement. Laveleye had the curious idea that the prospects of revolution were hopeless in Italy because malaria made Rome uninhabitable every summer. But Social Democracy, in its native country, does not stand or fall with Berlin. The truth seems to be that Italy, especially southern Italy, must go farther in industrial and political development before it is ripe for the reception of the new ideas, and still farther before it outgrows them. In too many parts of Italy the taxes and local rates are in no ordinary sense a heavy burden, and the people revolt from sheer despair. At the end of 1893 there was a formidable outbreak in Sicily, really against the tax-gatherer. The socialistic clubs called *Fasci dei lavoratori* actively aided the people; and though the rising was put down by military force, some lightening of taxation followed, and there was a general sympathy with the rebels. But the policy of the Government has been mainly repressive. It tried to suppress the Socialist Union, and (in October 1894) it put down 271 workmen's associations as socialistic. The State Socialism of the Italian Government of 1902 was not of a kind to compensate for this repression. The railways, owned by Government and leased to companies, are not well administered, and the management of the Bank of Rome in 1892 received a damaging exposure. There are as yet no effective Factory Acts. Professor Loria of Padua describes the labour law as "still mediæval." The professors in Italy are in advance of the statesmen in enlightenment if not in public spirit.

Italy.

Social Democracy might be expected to find disciples in Spain, as there is discontent in that country both among artisans and country labourers. Paradoxical as it may seem, the converts are chiefly country labourers, the working men of the cities (when they are not Anarchists) trusting more to their trade unions and other forms of self-help. Its weakness in the great northern nation, Russia, is due to entirely

Spain. Russia.

different causes. The principal is the strength of its rival, Anarchism, though the strength of the Imperial Government would by itself be enough to drive both of them underground. As Germany is the classical ground of Social Democracy, Russia is so of Anarchism; and in the history of revolutionary parties in Russia the Social Democrats have only a subordinate place. The Russian Socialists have many of them propounded a view which seems hard to reconcile with the "scientific" Socialism of Marx. They think that Russia might pass straight from its mediæval system of village communities to a system of Collectivism, without passing through the stage of modern Capitalism. They are unwilling to countenance the destruction of the village communities by modern industry. Yet Marx had laid it down that progress was necessarily from feudalism and a patriarchal system, through Capitalism, to Collectivism, Capitalism forming the necessary preparation (of materials and methods and men) for its successor. When Marx was directly challenged by his Russian friends (1877), he made the unexpected statement that the course of development need not be in that precise order unless the country itself so willed it. However, since 1877 the development of industry in Russia has made straight for Capitalism, and there will soon be no temptation for other Socialists to fall into the heresy, such as it was.

If Scientific Socialism requires for the final revolution only the full development of modern industry, enterprise, and invention, nowhere should we expect to find it so near the goal as in America or the British colonies. In the latter, it is true, there is little of the Socialism due to poverty; but there is much that is due (*a*) to the imperfect development of a new country, where there is a want of the accumulated capital utilized in the mother country by companies; and (*b*) to the greater power of the working classes, and the intelligent consciousness of that power.

Australia is the land of democracy, and even of socialistic democracy, of a certain kind. There is manhood suffrage; members of Parliament are paid (except in West Australia); the railways belong to the State; there is free education of the poor, when not of all and sundry. In South Australia women have the suffrage. In New South Wales the State owns the tramways, the water-supply, and the sewage works, and it gives subsidies to municipalities. The States of the Commonwealth are ceasing to pay settlers for coming to them; but they all (except New South Wales) keep up the imperfect Socialism of a protective tariff. Crown lands and mines are a chief source of revenue and expenditure. In 1897–98 more than one-half of the revenue of New South Wales was drawn

Australia.

from public works and services, more than one-fifth from lands, about one-fourth from taxation. In the case of England the proportions are (for 1899) about one-sixth from works and five-sixths from taxation, the income from lands being negligible (about one-two-hundredth).

But the young state of New Zealand, with a population of 800,000, shut off from Australia by 1200 miles of sea, and from the world in general by protective duties, is in some respects more like the "closed State" of the Socialist philosopher Fichte than any other State in the civilized world. Besides owning the railways, its Government is the largest land-owner and rent-receiver in the islands, possessing two-thirds of the whole acreage, and letting it on long leases. It limits the estate that can be held by any one individual, and has a right of compulsory repurchase. In 1893 it purchased the Cheviot property of 84,000 acres and divided the land into farms, now supporting about 900 prosperous tenants. The colonies for the unemployed, begun by Ballance in 1886, were less brilliantly successful; but about 5000 farmers, holding 20 to 50 acres on perpetual lease, are the result. The policy is that of the nationalizing not of rack rents, but of fixed ground rents. Of the State's intervention in other directions there is no lack. The working men of New Zealand drew together into strong organizations in the year 1890, their "maritime strike" following close on the London Dock strike of 1889. Ballance became the head of a Labour Party in Parliament, and eventually prime minister in January 1891. The result of the pressure of this new political party was a progressive income tax and land tax, an extension of the taxing powers of municipalities and local bodies, local option in regard to liquor (1893), a system of advances to settlers (1894), the adoption of the principle "one man one vote," the admission of women to the franchise (1892). The labour laws were extended and reformed on English lines as to Truck and Factory regulations and freedom of combination. A Department of Labour was created in 1891, and a scheme of compulsory arbitration in industrial disputes was passed in 1895. In Government works the "direct employment" of workmen, without a contractor, is the rule. In 1898 an Act was passed providing old age pensions of a shilling a day, under strict conditions of race, character, and income. Besides conducting the usual Post Office Savings Bank, the Government, since the crisis of 1894, has had control of the Bank of New Zealand; since 1871 it has conducted life insurance; it appoints a public trustee, who cares for the interests not only of widows and orphans, but of the Maoris; it does most of the conveyancing of land, though, as in insurance, without exclusion of private competitors. "The State, without being in any way a monopolist," says the Hon. W. P. Reeves, "is a large and active competitor in many fields of industry."

This tentative Socialism, in a colony unusually free from foreign elements, proves that a certain kind of Socialism is not un-English. It has still, for the most part, to abide the test of time. It is acknowledged that the railways of Australia and New Zealand, though efficiently worked, are not remunerative in the sense in which competitive railways running through similar districts in the United States are made to be so. They are often laid down by the Governments in advance of the demand for them, to attract settlers for the Crown lands. When allowance is made for this motive, the experiment may be said to prove, as it has done in very different circumstances in Prussia, that Government can manage a railway almost as well as a controlled private company. In regard to the Crown lands, it is clear that a new colony starts with an advantage that an old country could hardly recover, without unreasonable outlay; but, given the recovery, the machinery of administration might move as smoothly in the old country as in the new. But the Pensions and Arbitration Acts are unfinished experiments. The denser and more largely urban character of the English population, and the greater complication of industries, would prevent us from too readily drawing conclusions, even from the finished experiment; and it is significant that the birth-rate is declining in New Zealand much faster than in England. Politically there was centralization when the present state replaced the local governments in 1876. But the policy most nearly justified by success in the new state is rather that of drastic democratic regulation of Capitalism than the substitution for it of Collectivism. The Government tenants are allowed to keep nearly as much of the unearned increment as tenants elsewhere; the Maoris in the Reserve are allowed to become great landowners. No attempt is made to abolish competition in general business, but only so to regulate it as to secure healthy conditions of labour, and something like equal opportunities for the leading of a decent human life. No fear

of Collectivism need prevent a nation from trying to secure these benefits for its subjects in its own way, even if they are the benefits declared by the Collectivists to be only obtainable in their way.

The self-governing British colonies in the Antipodes have thus furnished valuable experiments in the direction of State Socialism. The paternal government of a dependency like India is less instructive, as being for the people, not by the people. America is in this respect a land of greater promise. Canada has paid members of Parliament, free education, Crown forests, and a Department of Labour; but is following England, not leading her, in social policy. It is not so across the border. Yet though the United States is a world by itself, it is entirely English in its attitude to Socialism. Like Great Britain, it is not fond of general principles of policy. But, unlike Great Britain, it has in its large continent a wide room for experiments. Though it sounds a paradox, its numerous experiments in Communism belong to Individualism; none are made by Governments, but by groups of individuals already under protection of Government. But the opening up of the West—Ohio, Indiana, Illinois, Missouri—was assisted actively by the Governments, which made grants in aid of roads, canals, and railways, and lent capital to settlers, or promoted banks for such loans. This eagerness to quicken the pace of industrial progress, in the United States as in the Australian states, is the mark of an irreflective State Socialism, hardly to be ranked with the State Socialism of old countries. At present the socialistic experiments go on more slowly; but they are nearly as various as there are states in the Union. Many states have a usury law, as once in England, fixing the maximum rate of interest on loans. Many states exempt homesteads from seizure for debt, an exemption extended in Texas to nearly all the customary goods and chattels of the settler. Wyoming and three other states claim control over all water; Indiana controls the use of natural gas; Maine, not to mention other states, forbids the sale of intoxicating liquors. These are only a few instances out of many.[1] The railways are not owned by the states, and the legislatures of the states are the scene of constant attacks on the railway companies. Decisions of the Federal Court in 1876 established the right of a state to a control over undertakings of the nature of monopolies. In 1887 the Federal Government itself, by the enactment of the Inter-State Commerce Law, exercised public control over railways running beyond one state into another.

America.

This is State Regulation, not State Socialism; and the same is true of the attempts under the Sherman Anti-Trust Law of 1890 and the numerous attempts of the legislatures of the individual states to deal with the great corporate combinations such as those formed to forestall and engross the supply of sugar, tobacco, soda, wall-paper, coal, indiarubber—to say nothing of the monopoly of oil under the Standard Oil Trust, and of steel under the Steel Trust of 1901. Trusts were thought to be specially dangerous in the case of articles deemed necessaries. Socialists of the modern scientific school have always regarded them as inevitable results of competitive trading, paving the way for the engrossment of all large industries by the State. But in America the mischiefs do not seem to be leading to the socialistic consummation. Trusts are seen to cure the evils of fluctuation, speculation, and wasteful overlapping. The people would prefer to see trusts controlled by Government rather than swallowed up in a Government trust.

[1] For a longer list, see Bryce, *American Commonwealth*, part v. ch. xcv., ed. 1895.

From various causes trade unionism is not even now so well organized in the United States as in Great Britain. With the formation of the Knights of Labour (1878) under Stevens and Powderly, there seemed to be growing up a new power in the country; but Powderly attempted impossibilities, trying to unite workmen generally, without regard to divisions of locality, or allowance for difference of skill or for rivalry between trade and trade. The Federation of Labour goes more wisely to work, dealing with particular grievances of particular trades, and pressing for redress of flagrant grievances. Appeal is made to the State mainly when the Federation has failed; action through the State is the second resource, not the first. The Convention of 1892 demanded Collectivism; the Convention of 1893 retracted the demand. Yet Socialism makes its converts, even in the New England states, and not simply among German immigrants. Henry George, on his return from England in 1883, formed the United Labour Party, to spread his views of the righteousness of a single tax on land rents, to displace all other State revenues. Henry George has been often hailed as an Individualist, and his "nationalizing of the land" stops far short of Social Democracy—the Social Democrats were expelled from the United Labour Party in 1887. But George's programme included more State intervention than is involved in the single tax. Almost the entire body of Socialists of all denominations supported his (unsuccessful) candidature for the mayoralty of New York City in 1886, when he received 68,000 votes. A village in Maryland tried (though in vain) to get legal powers to adopt his single tax (1893). Having made a convert of Father M'Glynn in New York, he imagined that the Pope's Encyclical, *De conditione opificum*, was aimed entirely at him; and he wrote an open letter to the Pope in reply (1892). George's death (during his second candidature for the mayoralty of New York, October 1897) did not end his influence, in some respects a very healthy one.

The Social Democrats have been represented since 1877 by the Socialistic Labour Party, consisting mainly of Germans. The aim of Edward Bellamy's *Looking Backward* (1888) was "to nationalize the functions of production and distribution," converting the United States into a gigantic industrial army under the generalship of the President, and so abolishing the evils of trusts and corners and modern competition generally. The *Nationalist Magazine* appeared in 1889 to advocate at first full-formed Nationalism, and afterwards, when the times seemed less ripe, experiments like Robert Owen's in the way of socialistic colonies. But the magazine died from lack of support in 1892.

Almost simultaneously with Nationalism, the People's Party, or Populism, sprang into being, at a convention of the Farmers' Alliances, Knights of Labour, and other organizations (1889). Its programme included (with some vacillation) abolition of the present banks, taxation for revenue only, Government ownership of railways and canals, free coinage of silver. This party was one of the chief supports of Mr Bryan in his unsuccessful campaign for the Presidency in 1896. It has taken its place as one of the fighting political parties; and it is hardly to be reckoned, except incidentally, a socialistic body. It has been well said that a Socialism which proposes, like Bellamy's, to abolish the separate states of the American Union, is therein attempting quite as hard a feat as the abolition of private property. The Populist Party is not fully committed to either attempt. Its members have little devotion to general principles, and would probably accept social reform with or without Socialism. Accommodation to altered circumstances is being forced on Socialists by experience, in America as elsewhere; and in

the experience of modern nations centralization is possible without Social Democracy, and decentralization without Anarchism.

Since the knowledge of opposites is one, to understand modern Socialism we must know something of Anarchism, which haunts it like its shadow, and resembles it only (though that is much) in attacking the system of private property as it now is. In America the Socialistic Labour Party is confronted with the Anarchist International Working People's Association. Anarchism has proved to be more truly international than Socialism. Social Democracy itself was felt by Marx and his disciples to be comparatively feeble unless international. Like modern Bimetallism, without an international agreement it may be crippled by the proceedings of nations that do not adopt it. The International Working Men's Association, founded by Marx in May 1864, was the practical scheme into which he threw himself heart and soul. He lived to see the International feared by all Governments on the continent of Europe. Its motto was that of the Communistic Manifesto of Marx (1848): "Proletariate of all countries, unite!" It held congresses at Geneva, Lausanne, Brussels, Basel, but survived the Paris Commune little more than a year; and after meeting in London (1871) held its last meeting at The Hague in 1872, when it expelled the Anarchists. A new International met at Geneva in 1873; and though from time to time International congresses have been held at the usual centres, the control of the International, in the narrower sense, had passed, from that year onwards, into the hands of the Anarchists. The old International had been successful in planting the ideas of Social Democracy over all the countries of the Continent; it had not succeeded in bringing about united action of the proletariate of all countries for the ends of Social Democracy. At the Ghent Congress of September 1877 the differences between the sections of the party led to sharp contentions. Many delegates declared themselves Anarchists: "Communism, 'they said,' is community and government; we desire Anarchism, which is community and anarchy." By "communism" they here understand Social Democracy, the communism of the Communistic Manifesto of 1848. This Manifesto, as compared with the contemporary plans of Louis Blanc for self-governing associations, seems to the Anarchists entirely retrograde. They dread the prospect of a government of industry after a military pattern; a strong centralized government is certain, they say, to be a tyranny. The most scholarly writers of the Anarchist Party (like Kropotkin, Elisée Reclus, and Tcherkesoff) consider that the pretensions of Marx to having founded a Scientific Socialism are unjustified historically, and that the Socialism itself is unjustified logically. They desire the abolition of all great central governments, and the establishment, in place of the present system of things, of groups of autonomous small communities, in which the individual man shall support himself according to his wants and capacities. But the Anarchist benefits us more by his keen criticism of defects than by his plans for reformation. Even in the soberest sections of the party it is hard to find men who reason out the way to their ideal.

Anarchism and the International.

We might divide Anarchists, very roughly, into three classes. There are, first, those who use the Universal Negative: they feel sure that political government as it is, is bad, and they would destroy all government; they are Nihilists. This is the class associated with deeds of violence. There are, next, those who would have Communism established without a central political government, but under a public control, exercised by local councils till the time come when public opinion will be a sufficient control by itself. William Godwin taught a similar doctrine in 1793. William Morris, when he left the Social Democrats, was drifting in this direction. There are, finally, the extreme Individualists, described in Carlyle's words as content with "Anarchy plus the street constable," and regarding the intervention of the State as a necessary evil, to be reduced to the smallest possible dimensions. These views are represented by Mr Herbert Spencer and Mr Auberon Herbert. They regard private property as the stronghold of individual liberty. They are rather an academic than a popular party. The really powerful party among the Anarchists is the middle party, disowning mere violence, and yet refusing to work in parliamentary harness, seeing no virtue in political government, even when representative. There is now a Parliamentary Socialism; there cannot logically be a Parliamentary Anarchism. Such a return to nature as is involved in successful Anarchism would be truly a revolution. The whole course of civilization hitherto has been hand in hand with law. The Anarchists would persuade us that there can be order without law, and a better order than with the best laws. But when they propose practical schemes, these are found to involve laws on a small scale, the laws laid down by the autonomous groups into which the Anarchists would break up present states. That such groups can live and work under the ægis of a State has been proved possible, but not that they can take the place of a State. Before the group could be secure against disturbance from without, it must either be under the shelter of a powerful military State, or rest assured that there is nothing but peaceable groups of like mind all around it. This last alternative would demand an international agreement, and a moral change in average human beings of a far more sweeping character than is required even for Social Democracy. If men cannot be made virtuous by Act of Parliament, neither are they so virtuous, or wise, or well-instructed as to dispense with Acts of Parliament. Anarchism, in short, seems, like the doctrines of the Society of Friends, on the whole too high for human nature, as we know it; and no convincing proof is given by the Anarchists that human nature is changing in the right direction so rapidly as to justify their aspirations. Moreover, if the change did take place, the world would probably have thereby become a tolerable world for us all even under the present system.

Both Socialists and Anarchists have claimed that the theory of Evolution, especially in the form founded by Darwin, tells in their favour. Mr Herbert Spencer has found it necessary to disclaim the socialistic conclusion in his own case. Evolution, in his interpretation, tends to Anarchism. But all the Scientific Socialists see in it the contrary tendency, with at least equal reason. Strictly speaking, the school of Marx and Engels ought to abstain from prediction altogether, and rest content with the reflection "What must be, shall be." The rest of the world, believing that human affairs are not fatally determined by purely economical causes, may criticize Social Democracy as an ideal, which it is perhaps in men's power to realize.

The Anarchists seem to be right in thinking that a strong central government, to which all power was given over industry as well as over all other departments of human life, would be contrary to liberty. Supervision would necessarily become more and more importunate, and great powers would mean great temptations to abuse of power, if men remain as we know them to be in all present kinds of government, bureaucratic, aristocratic, and democratic. The objection is not weakened if we take seriously the claims made by the old-fashioned Social Democrats for the supremacy of the working classes in the narrow sense

of the word. There is no reason to believe that working men are either better or worse than men of the other classes, and that they would behave differently under like temptation. Apart from actual tyranny of such a collectivist government, there might be a danger that individual initiative, however encouraged in theory, might be discouraged in practice. In fact, many of the objections found in old text-books of Political Economy have truth in them, and the Social Democrats show by their changed policy that they are well aware of this. It is true, however, that the objection from population applies to social reform generally, and not to Socialism in particular; and it is true that the objection from natural indolence applies less to Socialism than to Anarchism; Socialism would probably give not too much but too little indulgence to what it considered laziness.

The Anarchists, again, seem to be right in thinking that their rivals have misread the signs of the times in modern industry, and that the tendency towards concentration, both of businesses and incomes in fewer hands, is not the general rule. Gas and electricity seem likely to revive domestic and local industries. Great companies with some thousands of shareholders are becoming commoner than businesses held by single persons or families.

Even if all were tending to concentration, it is not easy to see how all is tending to prepare the bulk of the people for the revolution that is supposed to follow the concentration. Without more knowledge, self-control, and habits of business than they have now, the great world of the employed would not be fit to direct the course of industry and of their own employment. Without an industrial and moral preparation, therefore, Collectivism could not be a temperate and wise and permanent government. Yet the old-fashioned Social Democrats delighted in telling us that Capitalism made and kept men unfit for the higher functions of a human life by the bad social conditions it created. If the change is not to be sudden (and the modern Social Democrat usually admits this), then the necessary discipline must go on now, even under Capitalism; and it will fit men to use even their present opportunities better than formerly. Till they are capable of co-operation they are not ready for Socialism. The improvement of the workman is more important for the future of society than the improvement of the millionaire. There are signs that both are advancing together; and the result may well be that when men are ripe for Social Democracy, they will find Social Democracy superfluous.

Half a century's experience of Scientific Socialism seems to have served the cause of progress, though not in a way expected either by the Socialists or by their opponents. The programme of the Manifesto of 1848 has not been accomplished. The proletariate of all countries knows each other better, but the nationalities have not disappeared. Achievements in State Socialism have been carried out by the several states, each one for itself, modified sometimes by a common understanding, which is far from being united action. While the Social Democrats have gone the way of Marx, Germany, since German unity, has in one sense gone the way of Lassalle. The old fear of Socialism, as a sort of unknown force for evil, has given place to a familiarity which has bred deference, if not compliance. In Great Britain and America, Socialism has helped to popularize the serious study of industrial and social questions, where too many persons had been content with mother-wit and tradition. Socialism, by teaching that competition in industry is all evil, has taught many to distinguish between the good and the evil of it. Instead of killing Political Economy, it has caused a healthy revival of it. Politically, the old-fashioned Social Democrats insisted too abstractly on the all-pervading power of the State, as if that could replace the laborious ant-like efforts of its millions of subjects. But it helped to remind rulers that government is founded on opinion, and that the best way to avoid the need of the Social Democratic revolution is to make the government really democratic. At first the appeal to force was met by force; both parties have needed to learn that force without opinion makes no permanent institutions.

AUTHORITIES.—The list of these would be too long to quote in full. The German bibliography of Stammhammer, the handbook of Stegman and Hugo, and Warschauer's *History of Socialism* give endless references. Schmöle and Kulemann give the history of German trade unions. For the latest aspect of German controversies, see E. Bernstein's *Voraussetzungen der Sozialdemokratie*, 1899. For the general history, see Rae's *Contemporary Socialism*, 2nd ed., 1891; for that of America, see Ely's *Recent American Socialism*, 1885; and of New Zealand, Reeves' *Long White Cloud*, 2nd ed., 1899. For Anarchist criticism of Marx, see W. Tcherkesoff's "*Pages d'histoire Socialiste: Doctrines et Actes de la Social Democratie*" (from the *Temps Nouveaux* of 1896). For general references, historical, biographical, bibliographical, see the files of the *Economic Journal* (London), the *Quarterly Journal of Economics* (Harvard), and the *Political Science Quarterly* (New York).

(J. B*.)

SOCIAL PROGRESS IN GREAT BRITAIN.

IN common use the phrase Social Progress refers especially to the conditions under which the mass of the people lives rather than to changes which take place among the rich, and it is in this sense that it is used to cover the subjects dealt with in this article. Building is the most evident sign of development, and in the last twenty years of the 19th century the amount of building was remarkable. Great towns are now generally surrounded by new suburbs inhabited mostly by people with incomes under £300 a year. These suburbs have busy thoroughfares lined by shops, and long, straight roads, where each house has a little garden and some attempt at ornamentation. The number of houses in Great Britain of the annual value of £20 and upwards in 1878 was 18·9 of the total; in 1900 the number had become 22·3. The growth of such suburbs is, however, matched by that of others occupied by city merchants and rich people, whose houses are almost mansions, and stand in their own grounds. In 1900 there were 23,120 dwelling-houses in Great Britain assessed to house duty at an annual value exceeding £200 a year, as compared with 18,108 in 1878.

Building.

But perhaps the most conspicuous house-building of the period is that at holiday resorts. Whole towns have been built by the seaside, and places which, in the early 'eighties, were hardly known as villages have now a large population of residents retired from business, besides accommodation for thousands of visitors during the summer who have both time and money to take holiday. Within the great towns themselves the builders have not been idle. Slum dwellings have been cleared under Cross's Acts, 1875–82, and the Housing of the Working Classes Act, 1890; and on the spaces so cleared, as well as on others privately acquired, block dwellings have been erected. The character of neighbourhoods in the heart of great towns has thus been much changed. Instead of small tenement houses—built originally for the occupation of one family, but used

much more rapid in the second period. Along with better dressing and better feeding has come a greater sense of self-respect. People as a rule are more polite, if not more considerate; there is not the same horse-play on holidays; and notwithstanding outbreaks of "Hooliganism"—*i.e.*, riotous and brutal conduct by boys in the streets—people are more courteous, if not more gentle. Better health equally with better education has secured this result, and this is largely due to the development of sanitary science. Towns are more adequately lighted and cleansed, houses are fitted with more scientific appliances, and if water is still somewhat sparingly supplied, it is of decidedly better quality. The lighting of towns and villages has been improved. The standard of cleanliness in streets has been raised. The number of official inspectors has been doubled, often quadrupled, so that dirt is continually limited, defective drainage remedied, and foul places made sweeter. The sick of infectious diseases are immediately removed in public ambulances to a hospital situated in good air, provided with every appliance which skill and money can reach; and there they are nursed till they can be restored well and free of infection. In 1893 there were 587 local authorities in England and Wales who had provided accommodation for infectious diseases. Since that date, under the pressure of the Local Government Board, great strides have been made. There are now many more such hospitals. The healthy have the advantage of enjoying the open spaces, small and large, which have been made available. During 1898 the sum of £786,233 was expended on open spaces by various municipal authorities; in 1899, the sum of £805,592. Churchyards in crowded neighbourhoods have by this means been laid out so as to afford quiet places to sit and rest, and parks have been provided for the recreation of those who would enjoy the pleasure of walking amid the flowers, listening to music, or the vigorous pastimes of football or cricket.

An observer suddenly lifted from 1880 and planted in a town of to-day would perhaps first of all be struck by the pace at which things are done. Railway passenger traffic has greatly increased, electric trains and trams have been started, people run to and fro about the country and travel daily to their homes. It is computed by Sir J. Wolfe Barry that 1,000,000 persons enter and leave London daily by railways alone. In one hour 1228 vehicles and 5660 pedestrians pass through the Strand. In 1879 the metropolitan tram-cars ran 7,701,999 miles and carried 56,041,767 passengers. In 1900 they ran 31,679,397 miles and carried 337,058,869 passengers. It is impossible to show the absolute growth in London local railway traffic, as the great railways do not furnish returns for their suburban traffic separately from their main line and provincial traffic, but the distinctively metropolitan railways in 1879 carried 112,801,531 passengers, and in 1900 they carried 192,437,707 passengers. In 1882 there were 7,987,877 workmen's tickets issued by railways having London termini, and in 1899 there were 41,831,657 so issued, *i.e.*, a daily average of 134,507. The London General Omnibus Company carried 135,131,902 passengers in 1894, and 195,692,126 in 1899; the Road Car Company carried 44,610,320 in 1894 and 65,326,150 in 1899. The Metropolitan Police in 1881 issued licences for 5800 two-wheel cabs and 3847 four-wheel cabs, and in 1900 for 7531 two-wheel and 3721 four-wheel cabs. Work is everywhere done at increased speed, and the cost of such speed is to be found in the terrible death-roll of industry. It is stated in the report of the Royal Commission on Accidents to Railway Servants that in 1898, 542 servants were killed on the railways and 12,979 disabled; the proportion who suffer in mines is about the same. The total number of workpeople killed by industrial accidents in 1900 is reported as 4785—434 more than in 1896; and the total number injured was 104,464—46,982 more than in 1896.

Sunday is less quiet than it used to be. People wanting something to do get out of town by cycles or by trains; they go to concerts or picture galleries; they visit their friends and entertain parties. The Sunday League organizes gigantic excursions from town to town or from town to the seaside, the profits of which are spent in providing free or very cheap concerts of high-class music. The Sunday Society's long agitation for the opening of museums and picture galleries was crowned with success in 1896, when Parliament resolved that institutions under their control should be opened. The use made of the opportunity is at present not great. People are not sufficiently educated, and the numbers who visit the National Gallery show little yearly increase. The municipalities, with some notable exceptions, open the public libraries, and in many towns lectures are given.

Work is done and life is lived under greater pressure, but at the same time more leisure has been secured. A half holiday in the week is general, and the provision for week-end excursions is being developed; many trades have secured a nine hours' and some an eight hours' day. The leisure so gained is used largely in the enjoyment of sport, actively by some, and by a larger number as spectators. Schools are valued for their games as much as for their teaching; a hero of the football or cricket club is more honoured than a scholar, and nations hang on the issue of international contests. All classes seem equally to delight in the development and use of physical strength. Every town, almost every parish, has an athletic club, and every individual is interested in its success. A football match easily draws 50,000 spectators, sometimes 100,000, and every year the language is enlarged, if not enriched, and the thoughts of people modified, from the vocabulary of games. The development of athletics is matched by the increase of popular literature. In 1870 the total number of London newspapers filed at the British Museum was 224, provincial 667, Scotland 136, Ireland 154. In 1900 the London newspapers were 1226, provincial 1664, Scotland 282, and Ireland 222. Halfpenny papers have been started, and although no special returns are available, it is computed that every town of 45,000 inhabitants has such a paper. The number of periodicals is constantly increasing, and is now roughly computed at 21,000 per annum. The characteristic of both popular journals and magazines is news and stories shortly told. They seem meant for readers in a hurry who have no time to think, and they appeal to the more sensational side of human nature. The expiration of the copyright of many standard authors has thrown on to the bookstalls an abundance of good literature which finds a ready sale. Sport and newspapers together have opened greater facilities for the gambling which now takes a place near drunkenness as a cause of crime. Matches are got up not only for the sake of the show of skill, but to give opportunities for bets, and many newspapers obtain a large sale by supplying food for the gambling appetite. The statistics of drunkenness and of the efforts to control the drink traffic are given in the special sections below; but, speaking generally, the habit of getting drunk seems to have decreased and the habit of taking drink to have increased. The character of popular pleasure is what might be expected to follow an education which leaves the mind untrained to think and a life strained and hurried. People demand excitement at the least cost of mental effort. They like, therefore, as well as gambling and drinking, sports and sensational literature, exciting plays and songs. There has been a marked increase in the provision of theatres and music-halls. There is also a much

more widely spread desire to attract attention and to appear in print. Hence the growth of "personal" journalism. The question whether, with the love of excitement, sensuality has also increased cannot be answered by statistics; but judging from observation, from the tone of talk in clubs, and from the number of persons who require medical care in the infirmaries, it would seem as if less self-restraint were exercised. The occupation of their leisure by the people remains somewhat of a mystery. There are many trades which in winter leave off work at four o'clock. Some of the men so released may be found in continuation schools and libraries, some may frequent public-houses and places of amusement, but the greater number remain unaccounted for, and it seems fair to assume that they return to the homes they have built up by thrift, and spend the evening with their families reading, talking, doing odd jobs, or sleeping.

There has during the period been much more talk of religion, matched by a show of greater respect for religious agencies; but whether this means that the sanctions of religion are more powerful to inspire and restrain conduct, or to give peace and comfort, is a question not easily settled. Statistics would probably show that in every denomination there has been an increase of church membership, but the increase may be due either to the development of party feeling, which leads to zeal for opinion rather than for godliness, or to the interest in the social work undertaken by churches—and this is not necessarily a religious interest. The answer to the question can only be an individual opinion, but the opinion of the writers is that religion is less powerful than it was, say, in the 'seventies. It may be that then religion was more mingled with superstition, but it had a power to restrain and to give peace which it does not at present generally exercise over people whose thoughts have been widened with the process of the suns. Religion lies in a lower intellectual atmosphere than that which is commonly breathed, and does not therefore so deeply affect life. It has not kept pace with the general advance, and thus it is that people are not under authority; they are not bound to certain courses at the cost of profit or life, and they are not at peace when their world is turned upside down. The demand for excitement, the indulgence of vanity, the hurry of life and the absence of control have increased the tendency to mental disease, and one of the problems of the immediate future is the treatment of insanity. In 1881 there were in Great Britain less than 2 per 1000 of the population insane, and at the census of 1891 the ratio exceeded 3 per 1000.

The signs of the period which can be measured leave the inquirer seeking the spirit which lies behind. Perhaps it may be best described as an increased sense of individuality—a greater consciousness of a right to be. This spirit should show itself in attempts to realize the highest individual existence; but because a class of people who have few responsibilities to workmen, or tenants, or neighbours, and indulge themselves as they like, now occupy public attention and the most honourable places in society, it tends to show itself in a desire to escape toil and to reach a life as easy as that of the millionaires. Prosperity has increased the attraction of material comfort. The ideal of the individual is freedom from trammels and mastery over others. There is thus a widely-spread determination to have a good time while it lasts, and there is a growing impatience of control, whether it be that of authority, of public opinion, or even of responsibility for the future. One outcome of this disposition and this aim is to be seen in the spread of socialistic theory. Socialism seems to promise security to the individual to enjoy his life. It promises this result at once without the fatigue of thought, the exercise of

The modern ideal.

responsibility, or the weariness of waiting. It offers to remove the pressure of work, to rescue the individual who is being crushed by competition, and to give to each the means of material enjoyment. There may be some signs of a disposition to "think in communities" and of a tendency to subordinate the present to the future, but as yet the most powerful motive is the individual's longing to do the best for himself in his own time. Another outcome of this development of the sense of individualism is to be found in the prevalence of a more arrogant or insolent tone. There is thus at one and the same time a demand for the stricter enforcement of law to secure rights, and a defiance of the laws which are in existence. The "haves" incline to assume, and the "have-nots" incline to rebel. They who are strong tend to show their strength. Hence come some of the extravagances of fashion, the lawlessness in high places and low places, the impatience of reforms whose fruits are in the future. The prevalence of this sense of "a right to be" is not inconsistent with the increased care for others which is shown in legislation, in charity, and in the administration of law. *Succès oblige.* People who have a high sense of their own claims recognize the claims of their neighbours; and there is undoubtedly, alongside the increased demand for more of the good things of this world, an increased goodwill to grant such things. The conqueror is often kind, and there is a certain pleasant pride in being generous. Much has been done; the progress of a generation measured by figures is immense; but there are still many old ills of society waiting a remedy—poverty, ignorance, and suffering. There are other ills—vanity, love of mastership, and the desire for pleasure—which seem to be taking a deeper root. (S. A. B.; H. O. B.)

Baths.

It was not till 1846 that it was deemed advisable, for the "health, comfort, and welfare" of the inhabitants of towns and populous districts, to encourage the establishment therein of baths by the local authority acting through commissioners. A series of statutes, known collectively as "The Baths and Wash-houses Acts, 1846 to 1896," followed. By the Public Health Act, 1875, the urban authority was declared to be the authority having power to adopt and proceed under the previous Acts, and in 1878 provision was for the first time expressly made for the establishment of swimming baths, which might be used during the winter as gymnasia. By the Local Government Act, 1894, it was provided that the parish meeting should be the authority having exclusive power of adopting the Baths and Wash-houses Acts in rural districts, which should, if adopted, be carried into effect by the parish council. Up to 1865 it seems as if only twenty-five boroughs had cared to provide bathing accommodation for their inhabitants. There is no complete information as to the number of authorities who have adopted the Acts since 1865, but a return of reproductive undertakings presented to the House of Commons in 1899 shows that 110 local authorities outside the metropolis applied for power to raise loans to provide baths, of whom 48 applied before 1875 and 62 after 1875. In 1900 the loans sanctioned for the purpose amounted to £83,294. No loan at all has been raised by any parish council for baths, and the total receipts for the year to 31st March 1899 of such councils under the Baths and Wash-houses Acts was £127. In the metropolis, by the Local Government Act of 1894, the power of working the Act was given to vestries, and by the Act of 1899 this power was transferred to the borough councils. There are 35 parishes in London in which the Acts have been adopted, all of which except 11 have taken

action since 1875. These establishments, according to the return made in 1899, provided 2539 private baths and 85 swimming baths. The maximum charge for a second-class cold bath is 1d., for a hot bath 2d. In 1897–98 the number of bathers was 4,463,109, of whom 2,347,958 were bathers in second-class private baths and 2,115,151 bathers in second and third class swimming baths. In the previous year the gross total had been only 2,000,000. In cases where the proportion between the sexes has been worked out, it is found that only 18 per cent. of the users of private baths, and 10 per cent. of the users of the swimming baths, are females. In 1898 the School Board was authorized to pay the fees for children using the baths if instruction in swimming were provided, and in 1898 the privilege was used by 444,111 children. The cost of this public provision in London—largely on account of the high rate charged for water (£12,522 was paid in 1897–98)—is over £80,000 a year, which has to be paid by the ratepayers. No account can be given of the numbers using the ponds and lakes in the parks and open spaces, but it is computed that on a hot Sunday 25,000 people bathe in Victoria Park, London, some of the bathers starting as early as four o'clock in the morning. These returns show how great is the increase of the habit of bathing, but they also show how even now the habit is limited to a comparatively small part of the population. People require to be tempted to the use of water, at any rate at the beginning. There are still authorities in London responsible for 800,000 persons who have provided no baths, and those who have made provision have not always done so in a sufficiently liberal and tempting way. The comparison between English great towns and those of the Continent is not in favour of the former, but the growth has begun, and promises to go on. Swimming clubs have become common; the contests awake much interest, and the demand for more accommodation is likely to be heard. (S. A. B.; H. O. B.)

Clubs.

Workmen's clubs are a product of the last twenty years of the 19th century. The first were institutes, and liquor was not introduced till 1868. They can be registered under the Friendly Societies Act, but as there is no obligation to do so, the return of 802 registered clubs in England and Wales is no evidence as to their number. In 1900 there were 54 workmen's clubs registered, and at the same time "an enormous growth of dubious clubs." The Working Men's Club and Institute Union has collected returns, and gave evidence before the Licensing Commission, presided over by Lord Peel, that in 1896 there were 3991 clubs in which intoxicants were sold. Of this number 660 were in London, 1583 in English counties, 1291 in English boroughs, 122 in Wales, 157 in Scotland, and 178 in Ireland; 313 are returned as proprietary clubs, but these cannot represent the real number. As regards subscriptions, 1098 have an annual subscription of £1 and over, 1158 from 5s. to £1, 1405 from 2s. to 5s., and 329 stand at 2s. or under. Rather more than one-half the clubs open on Sunday, with a large proportion in Wales and Ireland. On week-days 1582 are open after 11 P.M., or in London after 12.30 A.M.

There is no available record showing the increase of clubs; but it is known that, of the 3991 existing in 1896, there were only 2160 in 1887. According to the returns of the Union, it seems that in 1890 there were 328 clubs affiliated, and in 1900 there were 708. The secretary reports that of these 650 have been started since 1882. The clubs are social or political, drinking or teetotal. The drinking clubs are entirely self-supporting, and sometimes own the buildings they occupy; the teetotal clubs are generally subsidized. In the drinking clubs the average spent per week on drink is one shilling and a farthing per member. There are various opinions as to the object and use of clubs. On one hand it is contended that they exist to provide means of drinking when the public-houses are closed, that they are a fruitful cause of drunkenness, that the spirit of gambling is promoted, and that the entertainments are often of a low character. It is reported that during ten years 352 clubs were closed by the police or the excise. On the other hand it is urged that the clubs against which such charges hold are few in number, and such as should be restricted by police action; that they have been generally formed to promote good fellowship; and that in most of them there is a development of a higher taste and a sense of social duty. In support of the latter opinion the Union offers evidence as to the increased use made of libraries, as to the number of club members holding office on local governing bodies (2320 in 1901), and of the ever-widening interest taken by members in the affairs of the world. The Union, however, acknowledges an increased love of pleasure compared with the increased love of knowledge. The number of clubs having Sunday lectures has decreased, while those having Sunday entertainments and games have increased. The proportion, too, of political to social clubs goes on decreasing. On the whole it may be said that the clubs accurately enough represent the features of the time—the improved conditions which leave men leisure, the possession of knowledge which longs to spread itself in fellowship, the love of pleasure which looks for the easiest ways of satisfaction, and the dislike of restraint which is happy in a club where no one has a master. The Licensing Commission, approving of the benefit to be derived from properly constituted clubs, unanimously recommended a system of registration under such conditions as to ownership and management as would prevent individuals benefiting by the sale of drink or the admission of persons under 18 years of age. (S. A. B.; H. O. B.)

Housing.

The first legislation on this subject was due to Lord Shaftesbury in 1851 and to Mr Torrens in 1868, but for many reasons the laws were not effective. The principle, however, was asserted that the responsibility of maintaining houses in proper condition falls on the owner, and that if he fails in his duty the law is justified in stepping in and compelling him to perform it. In 1875 and 1879, when Lord Cross was Home Secretary, the Government brought in Acts, and a subsequent Act in 1882, "to deal with the whole area where houses are incapable of repair," giving the local authorities compulsory powers to enter as purchaser (but at the commercial and not at the housing value) and proceed to reconstruct. Something was done under the powers thus conferred, but in 1884 the public mind was deeply stirred by revelations about the condition of the poor. A pamphlet published by Mr Mearns, of the Congregational Union, entitled *The Bitter Cry of Outcast London*, described a state of things in which health and decency were impossible. A Royal Commission, of which the then prince of Wales was a member—"one of the most powerful commissions ever chosen"—was appointed in 1885 to inquire into the housing question. Its action brought many details of poor life to light, but its report was followed by the Housing of the Working Classes Act of 1890, which, however, did no more than consolidate all previous Acts.

The Housing of the Working Classes Act, 1890, is divided into three parts. Part I. deals with large areas. When twelve ratepayers call upon the medical officer to investigate a neighbourhood

in which houses exist which are regarded as unfit for habitation, or when, without such a call, the medical officer represents to the local authority that an area is unhealthy, the local authority must consider the representation, and, if satisfied, make an improvement scheme. This scheme has to be approved by the Secretary of State, who will issue a Provisional Order (afterwards to be confirmed by Act of Parliament), which the local authority must obey. Part II. applies to small unhealthy areas and also to individual houses. In the former case the local authority may prepare a scheme on its own initiative, which must be confirmed by the Local Government Board, but no Act of Parliament is necessary. In the latter case, when any house is declared unfit for habitation the local authority may obtain from the magistrate an order for closure and demolition, but the procedure to obtain these orders is beset with difficulties. Part III. gives the local authority power to acquire land compulsorily or by agreement, and erect thereon lodging-houses, separate houses, or cottages containing several tenements.

In carrying into effect schemes under the Housing Acts the Metropolitan Board of Works from 1875 to 1889 displaced some 27,000 persons of the working class and secured the provision of accommodation for approximately the same number. Since 1889 the London County Council has, under the Act of 1890, displaced some 10,000 persons, and under various other Acts some 3000 more. In lieu of the accommodation thus destroyed the London County Council has itself erected dwellings for some 15,500 persons. The net cost of all operations carried out by the Metropolitan Board of Works and the London County Council under the Housing Acts from 1875 to 1901 amounts in round figures to £2,700,000, while the total cost of all works under the Acts (including the remunerative expenditure on dwellings) amounts approximately to £3,500,000. The London County Council has in connexion with its dwellings a rent-roll which now exceeds £40,000 per annum. Mr Blashill, the Council's former architect, thinks that after allowing for the street improvements involved it might be fair to say "that the net loss on the council's housing schemes amounts to £45, or possibly £50, for every person displaced."

In 1898 the council determined to take further steps under Part III. "with a view to the purchase of land and the erection of dwellings thereon," independently of any clearance or improvement schemes. About 40 acres at Tooting were acquired, and subsequently 225 acres at Tottenham to house 40,000 persons, and 30 acres at Woking to house 6000 persons. The borough councils, under the Act of 1899, also have power to put in force Part III. of the Housing Act. The possibilities of work are immense, in the light of the fact disclosed by the census of 1891 that 214,843 persons in London lived in tenements of one room, and 330,238 persons in tenements of two rooms. The census of 1901 showed, however, that progress had been made. The number of one-room tenements in London has declined, and whereas in 1891 there was 9·2 per cent. of the population in such tenements, there was in 1901 only 6·7; whereas tenements of five rooms, which in 1891 were 32·7 per cent. of the whole, rose in 1901 to 34·1 of the whole. The rate of increase during the decade in larger tenements has been exactly double that shown in smaller tenements.

The Cheap Trains Act of 1883 has had a direct bearing on housing by tempting railways to provide workmen's trains. The passenger duty is reduced on condition that cheap trains are run between the hours of 6 in the evening and 8 in the morning. The Great Eastern Railway has thus issued return daily tickets at 1s. a week to stations within 12 miles of London. The consequence has been the great extension of workmen's suburbs in the eastern districts. Other companies have been compelled by the Railway Commissioners to provide additional trains. The effect is shown in the decrease of the growth of population within the London area. Between 1891 and 1896 the rate of increase was 4·8 per cent.; between 1896 and 1901 it was 2·4 per cent. In the ten years preceding 1901 the loss by migration from the county of London exceeded 180,000.

The Public Health and Building Acts have also directly or indirectly affected the housing question, rendering it more easy to condemn houses as unfit for habitation, and making it more difficult to build houses with insufficient or ill-adapted provision for health and comfort. In 1899 the Government passed an Act by which the local authority may advance a sum not exceeding £250 to enable the resident or the intending resident of a house not exceeding £300 in value to purchase such house, but little use has been made of its provision.

Public action by Parliament and local authorities has been more than equalled by the individual work of philanthropists, companies, and builders. The Peabody trustees (1862) and the Guinness trustees (1889) have in some instances bought land cleared by the public authority, but in most cases have secured sites in the open market. There are smaller trusts in some of the great towns: they all build block dwellings, and let tenements at rents which pay a small interest on the capital sum. The receipts accumulate, and are invested in further buildings. Rules are of course necessary, and criticism is sometimes provoked. It is objected (1) that the buildings are too much in the nature of institutions; that people need houses, not rooms in a barrack, and that a family should have a house with easy access to the street; (2) that the tenants who benefit by the somewhat lower rent are not the very poor, and are privileged; (3) that the provision of houses out of charity limits provision in the way of business. But at all events the houses so built have been an education both to their inhabitants and to society. Philanthropic action has not exhausted itself in founding trusts. Miss Octavia Hill has shown even a better way of meeting the housing difficulty. Before the agitation, as far back as 1864, she and Mr Ruskin, feeling that the housing of the people lay at the root of many social evils, obtained possession of a court of low-class property. Miss Hill gathered round her a group of volunteer workers, and, by applying character to character, endeavoured to raise the tenants as she improved the houses. Her plan answered: the houses were made habitable; broken woodwork was made sound; sanitary conditions were gradually—too gradually, it often seemed to impatient reformers—put in order; small playgrounds were secured; and rents were so regularly paid that the owners received fair interest on their capital. By 1902 she herself controlled houses occupied by 1268 families, and her system of management by means of lady visitors has largely extended in London and in many English and Scottish towns. Miss Hill thus originated a way of dealing with the occupants of the lowest class of house which has largely modified the views which are taken of the problem. It is now seen that it is useless merely to put people displaced from their hovels into model dwellings. They will not submit to order; they must be themselves educated, and the change must be gradual. Another result of the Royal Commission was the formation in London of the Mansion House Committee for Improving the Dwellings of the Poor, and of like committees in other towns. These committees have done particular service in bringing public opinion—and sometimes the decisions of the law courts—to stir up inactive local bodies. There are many clauses in the Building Act and in the Public Health Acts which are not enforced. Local bodies have sometimes a sympathy for local landlords; at other times they are unacquainted with the law. The Mansion House Committee, by means of local committees and by employing its own

inspectors, has brought this neglect to light, and in many districts a higher standard obtains. One fact is sufficient to illustrate the progress. In 1885 there were 89 sanitary inspectors over the London area, in 1898 there were 256. In 1878 there were 930 sanitary inspectors recognized by the Local Government Board, and in 1898 the number was 1822.

The housing of the poor has also been taken up on purely "business" principles. A company with this object was started in 1864, but the first notable success was scored by Sir Sidney Waterlow. His company has laid out £1,000,000, and housed over 30,000 people, and the death-rate stands at 9·95 per 1000. The Artisans', Labourers', and General Dwellings Company has invested 2½ millions. Companies on this model are now numerous in many of the great towns, and generally yield a fair dividend. Of late years, however, chiefly by reason of the increased expense of building, or in a less degree by the competition of municipal bodies, the companies have almost ceased to build. The weekly rents paid for rooms in these block dwellings in London average 2s. 6d. or 3s. a room. Private builders have in some instances erected blocks on a like plan to that adopted by the companies, but their activity has been chiefly shown in building cottages in the suburbs. They are often condemned as "jerry builders," but the condemnation is probably used in too wholesale a way; most of the cottages and houses which are now occupied on the outskirts of towns are convenient and sufficiently substantial. In 1878 there were 17,127 new houses built in the metropolitan police district; in 1900 there were 25,161. If, therefore, the Royal Commission was followed by no great measure of reform, there has been decided improvement.

The improvement, however, leaves much still to be done, and it has hardly touched the country districts. The mischief is now, however, much more that of overcrowding than of uninhabitable dwellings. Many causes have in late years tended to aggravate the evil. Agricultural depression has impoverished country employers and prevented the building of cottages, and good trade has brought people into towns. The high wages demanded by trade unions have almost doubled the cost of building—the cost per room in London is now £108, against £70 in 1891—and people being better off, demand more room. Overcrowding, according to a London County Council report, is more excessive now than in 1891. Various solutions of the problem are urged:—(1) Local authorities have been pressed to use their powers under Part III. of the Housing Act to acquire sites and build, even at a loss to the ratepayers; and further, to obtain powers to borrow at an easier rate, and to purchase sites outside their own boundaries. (2) Local authorities have at the same time been advised to interfere less. They are told that their restrictions on the character of the building, and on the number of occupants of a room, are absurd, and that business people, who would at once supply the demand for houses, are deterred by fear of competition supported by the rates. They are warned against creating a privileged class of workmen who have better accommodation or less rents than their neighbours, and may form a constituency who will press their private interests so as to corrupt the governing body. (3) Parliament is asked by some reformers to introduce new methods of rating to make vacant building land subject to rates, and to divide ground values from building values, so that rates may fall on the former. (4) There are others who see no remedy but in dispersion of the population; they advocate the provision of cheap and easy methods of locomotion by means of railways or tram-cars to every part of the circumference of great towns. They sometimes add a hope that power may be given to the local authority to acquire land on this circumference on some fair system of payment, so that sites may be available for either municipal or private building. The proposal of so many remedies shows the urgency of the question. It is long since Lord Shaftesbury first succeeded in drawing public attention to the evil of housing, but it is only since 1875 that efforts have been really made to abate the evil. Figures quoted above indeed show that the population is already tending to move from the centre to the outskirts, and the ambition for a bit of garden or for a sight of the country is more widely expressed as hours of labour are decreased. To a certain extent a remedy is thus being found by a natural process, and it is often urged that overcrowding is due chiefly to insufficient means of locomotion.

There is one class of people outside the working class whose condition especially attracts attention. This is the class found in casual wards, shelters, and common lodgings. It includes some workmen, but derives its character from the presence of many broken-bodied and broken-hearted men and women. These people—ragged and starved—are frequently found on door-steps and under arches, and awaken general sympathy. "If," it has been thought, "there were decent lodging-houses, where health and order could be secured at a small charge, many would be comfortable who are now driven to despair by discomfort." The managers of the Victoria Homes and Lord Rowton have met this need in London by forming companies to build lodging-houses, and the London County Council has itself opened a "doss-house" on the same lines. In some of the great towns—notably in Glasgow, where also a Family Home has been opened—a like provision has been made. The contrast between the new common lodging—a workman's hotel—and the old common lodging house is very striking. Any man who can pay 6d. a night may be secure of privacy in his bedroom and of cleanliness in his surroundings, of a bright sitting or reading room, and perfect order in the arrangements. The only doubt which clouds the satisfaction at the change is lest such good provision for single men may lead them to prefer single life to the responsibility of a home. These model lodging-houses do not, of course, affect the great mass of the class just mentioned. These people cannot pay 6d. a night, and will not endure order; they therefore take refuge in shelters and casual wards, or go to some cheaper lodging. (S. A. B.)

Pauperism.

Pauperism, measured by figures, has greatly decreased in England and Wales. In 1870 the number of persons who received relief was 46·5, in 1850 it was 57·4, per 1000 of the population. In 1899 the number was 26·5 per 1000. In Ireland, however, there has been an increase. In 1870 there were 74,000 paupers, and in 1899 there were 103,866, with a diminished population, but between 1890 and 1901 the tendency was to a decrease in the number. In Scotland there has been comparatively little change, but the tendency is upwards, and there were in 1899, 65,929 paupers with 33,994 dependants. At the same time the money spent on those relieved has greatly increased. Whereas in 1850 a mean number of 123,004 indoor paupers cost £914,264, or £7, 8s. 8d. per head, a mean number now of 216,200 indoor paupers costs no less than £11, 0s. 7d. per head. The change is due to the improved circumstances in which people live, the larger wages, the sanitary improvements, the better education, and the opportunities of saving, but still more directly to the more considerate treatment

which has been introduced into poor-law administration. Pauperism in one sense is the creation of law, or rather of its administration. People may in time of poverty get relief, and go back again to be self-respecting wage-earners; but those who in time of poverty learn to depend on relief grudgingly given are paupers, and the increase of pauperism is largely affected by action which encourages dependence and destroys self-respect. The more humane and thoughtful treatment which during the last twenty years of the century helped to reduce pauperism is shown —(1) in the improvement of infirmaries, workhouses, and casual wards; in the separate provision made for infectious disease, imbecility, and other forms of mental defect; and in the impetus given to voluntary effort in developing the possibilities of malformed or deficient persons by the increased number of homes certified by the Local Government Board adapted to the training of difficult cases; (2) in the provision made for children; (3) in the attention given to the administration of out-relief (see POOR LAW).

(1) The infirmaries—in towns at any rate—in which the sick poor are nursed are now under the care of highly-qualified medical officers, with assistants, and a full staff of trained nurses. The buildings have been altered or built to suit modern requirements, and the medical officer has, in practice, unlimited authority as regards the ordering of necessary "sick comforts," while increasing advantage is taken of special institutions for special diseases or special needs. In London the Metropolitan Asylums Board is a body representative of the several poor-law divisions of London, upon whom extensive duties are imposed by the legislature. When it is observed that its expenditure during the last twenty years of the 19th century reached the amount of 9½ millions, that during the year ending Michaelmas Day 1900 this body expended no less a sum than £832,466, that each bed has often cost £400 to £550, and that the normal accommodation of its twelve fever hospitals and its five imbecile asylums and its five institutions for ophthalmic and other children is more than 15,000 beds, the magnitude of its work will be appreciated. Apart from the provision for smallpox patients which is incumbent on the managers, it devolves upon them to provide and administer a training ship for pauper boys of the metropolis, to organize and maintain an efficient land and river ambulance service, and to provide establishments for special classes of children. In the country districts, and notably in Ireland, reform still lags, and there are many cases where the workhouse characteristics are obvious in the infirmary, where the wards are depressing, and where nursing and treatment are not at the same high standard as in London and many urban centres. By an order, however, of the Local Government Board of 6th August 1899 the employment of any pauper inmate to perform the duties of a nurse was forbidden, while the employment of a pauper inmate in any other capacity in a sick ward must have the approval of the medical officer and be subordinate to the supervision of a paid officer. There has not been the same improvement in the position of the able-bodied; but here too, in many instances, guardians have aimed to educate rather than to deter those who seek relief. They have substituted trades for oakum-picking and stone-breaking, introduced visitors, who interest the able-bodied by talk and reading, or offer them openings and inducements to a working life. They have, in some instances, made it possible for men of more solid determination to get work on the land, and thus train themselves for emigration. The greatest problem has been and is to deal with the vagrant population. In 1882 legislation, following an inquiry, made it lawful to detain people using casual wards over a clear day if they were proved *habitués*.

The exact terms of the law are:—That a casual shall not be entitled to discharge himself from a casual ward before 9 o'clock in the morning of the second day following his admission, nor before he has performed the task of work prescribed for him; and where a casual pauper has been admitted on more than one occasion during one month, he shall not be entitled to discharge himself before 9 o'clock in the morning of the fourth day after his admission. This latter regulation, however, is modified by an order of the Local Government Board of 18th December 1882, which provides that a casual pauper, who has been detained for more than one night, and who represents to the master of the workhouse or superintendent of the ward that he is desirous of seeking work, shall, if he has to the best of his ability performed the prescribed task of work, be allowed to discharge himself between Lady Day and Michaelmas Day at half-past 5 in the morning, and between Michaelmas Day and Lady Day at half-past 6 in the morning.

The same policy of restriction has been followed in the recommendation of cellular wards by the Local Government Board. Guardians have thus at great cost added a sort of prison to their establishment, in which casuals are confined sometimes for four days in solitary confinement and forced to do certain task work in oakum-picking, stone-breaking, grinding corn, or cutting wood. There is a division of opinion among poor-law administrators as regards the result of the policy. On the one hand it is contended that any failure is attributable to the absence of uniformity of treatment; on the other, that such treatment must tend to harden in their ways the somewhat limited number of persons who prefer casual wards to common lodging-homes. In the country the habit of vagrancy does not seem to be checked, but under other influences which make lawlessness easy is even increasing. The number of vagrants relieved on 1st January 1878 was 5108, and on the same date in 1901 the number was 11,658.

(2) The greatest change has been in the treatment of children following on the interest aroused before and by the Education Act of 1870. It was felt that it was unjust and short-sighted to punish the children of paupers by shutting them up in workhouses or by giving them inferior education. The desirability of withdrawing children from workhouses was recognized by the legislature as far back as 1844. The Poor Law Amendment Act of that year empowered the commissioners (now the Local Government Board) to combine poor-law areas into school districts for the management of any class of infant poor not above the age of 16 years. Separate schools were in consequence formed. The schools have been continually improved. Village communities with cottages accommodating from 10 to 30 children have in some cases been substituted for the block buildings, and no expense has been spared, the cost sometimes amounting to £190 per bed. The annual charge for each child's keep then reaches £32. In 1873 Mrs Nassau Senior, the first woman inspector, found the results, at any rate on girls, to be unsatisfactory. It was agreed that more individual treatment was wanted, and many improvements were made. The Metropolitan Association for Befriending Young Servants was formed for the after-care of the girls, and an impetus was given to the practice of boarding out children in the cottages of villagers. The system, however, of aggregating children in large schools continued; and as outbreaks of ophthalmia and other diseases, and disclosures of cruelty and neglect occurred, another inquiry was held, and in 1896 a departmental committee reported, condemning the system of aggregation. Orders were in consequence issued by the Local Government Board for the breaking-up of some of the largest establishments, and encouragement has been given for the adoption of various plans of scattered homes by which parties of children under the care of a house mother are able to join in the life of a community and profit by contact with other children. A perpetual difficulty in dealing with children is the prevalence of a class

of "ins and outs," *i.e.*, of children who are dragged about by vagrant parents, and frequently come in and out of the guardians' hands. With a view to getting control of certain classes of children, a law was passed in 1889 which gives the guardians power to adopt children who may be deserted by their parents, and take upon themselves all the parental powers, even to the extent of emigrating such children. In 1899, by the efforts of the State Children's Association, which was formed to carry into effect the recommendations of the committee of 1896, these powers were extended to include any child the parent of which is, in the opinion of the guardians, by reason of mental deficiency, or of vicious habits, or mode of life, unfit to have control of it.

(3) In the 'seventies social observers were struck by the misuse of charity and its competition with the out-relief given by the guardians. The effect was seen in the increase of dissatisfaction and of poverty. Large sums were being given, some of the recipients being drunken and others starved. An attempt was therefore made to organize charity, and to lay down some principle on which out-relief should be given or refused. Some guardians determined to stop giving out-relief altogether, and carried out that policy. There are different opinions as to the success. On one side it is urged that the people are better off. When relief was given by no comprehensive rule, many poor persons were induced to waste time and strength and character in its pursuit. On the other side it is urged that the needs—especially of the old—cannot be met out of earnings or charity. The facts, in a union like Whitechapel, are that in 1872 there were 1000 indoor and 1568 outdoor paupers, out-relief costing £4730. In 1895 there were 1503 indoor and 5 outdoor paupers, out-relief costing £29. The net result has been to put a limit on pauperism. When the policy of abolition has not been followed, there have generally been more care and more discrimination; and up to 1893 the yearly diminution was regular. In 1894 a change was made in the qualification of the guardians, and the *ex-officio* members—that is, the magistrates—were removed, and the office thrown open practically to all ratepayers, men or women. The persons thus elected have not had the same experience in administration, and have inclined to meet poverty by grants of out-relief. There has been in consequence a slight rise in the pauperism. In the country districts the boards of guardians, under the Act of 1894, have been made identical with the rural district councils. The same members have thus different interests, and it is calculated that they will be less under the sway of policies or parties or classes, and more able to follow the lines laid down by experience.

The net result of a survey of pauperism is that the number of persons in receipt of relief is reduced, and that those who enjoy relief receive it in a better way. The change is due to many causes, and it is possible that what may be called the more scientific method of administration is the cause which has least popular approval. Sentiment favours liberal giving and liberal treatment; prosperity has made liberality possible without undue pressure on the ratepayers. Progress, therefore, does not seem to rest on a secure basis. The lavish expenditure may induce such larger numbers of the sick and afflicted to make use of the State provision for their diseases as to cause a reaction. (S. A. B.)

Amusements.

Holidays imply cessation from work; amusements imply relaxation in work. The provision of means of amusement has extended in every direction. There are more theatres, more novels, more entertainments, and more games. People seem either to work so hard or to find work so dull that they look for amusement which will demand as little effort as possible. The theatres thus incline to afford spectacles, and the novels to give strong sensation. The popular game is football, which provides observers with an interest almost like that of a battle; and people seem to be less and less inclined to join in a game at all, unless it be for the excitement of a prize or of popular notice. There is an increase of athleticism, but it is largely mixed with sport; men practise to take part in contests, and there is less simple healthy pleasure in exertion. People, that is to say, depend for amusement on something outside themselves, just as the children look for toys. A striking feature in advertisements is the offer of all sorts and kinds of toys. Those who are older than children look for something to stir their minds, be it a scene in a play or a contest in sport. The obvious amusement is something exciting—a play, a race, a contest; but alongside there is an increase of other amusements which depend on the exertion of mind and body. There are now picture galleries in many of the great towns; sketching clubs and rambling clubs are formed among young people; music is provided by many town councils; and people are gradually developing a love of social meeting, as by travel and reading they find more subjects for conversation. The period, again, is one of transition. The hard worker in his first freedom from work turns naturally to the excitements which most easily stimulate his senses; but as with more leisure he develops the powers of his mind, he begins to find satisfaction in their use. A review of the means of amusement now provided shows how largely those which excite predominate, but closer observation shows that at the same time there is a growth of other amusements which involve the exercise of the mind and taste. (H. O. B.; S. A. B.)

Clothing.

Observers with memories going back to the 'seventies see that people are as a rule better clad in 1902—more warmly, more appropriately, and often with more taste. Many things have combined to bring about the change. There has been a rapid succession of inventions in clothing making, and especially in boot-making. Women's boots which formerly cost 9s. can be bought for 6s.; good boots for children can be got for 3s. 6d. New sorts of stuffs have been made available, some of which are as serviceable as the more highly priced materials they have displaced. Methods of distribution have also been improved. Large shops or co-operative stores have lowered prices; enterprising traders quickly distribute bankrupt stocks; and the sale and translation of second-hand clothes have been better organized. Education has at the same time developed self-respect, and people tend, therefore, to adopt the same fashions. There are few workpeople who do not appear on Sundays in the same style of dress as that worn by their employers. The clothing of the poor—as far, at least, as outside appearance goes—is always a subject of astonishment. The only classes which look wretched are not those who earn least—widows and labouring families—but the careless and thoughtless, who often earn good wages. Students who have gone into the subject estimate that clothing costs a grown person 6d. a week and a child 5d. But such clothing, if enough for appearance, is said to be insufficient for warmth or protection from weather. (H. O. B.; S. A. B.)

Crime.

During the twenty years from 1881 to 1900 there was a definite diminution of crime in England, but to estimate the amount of the decrease is a matter of some difficulty. The error has been made by some of treating as a measure

of crime the average prison population, which fell from 28,324 in 1880 to 17,435 in 1900; but prison population depends not only on the number of persons sent to gaol, but on the average length of their sentences, and the fall is one mainly due to the increasing leniency of the sentences passed by judges and magistrates. Others, again, have fallen into the opposite error of founding conclusions on the number of technically "criminal" charges, which increased from 649,811 to 770,853; but in this case the augmentation is due, not to any growth of crime in the proper sense of the word, but to the establishment of new municipal regulations in the interest of the public safety, health, or progress. Within the last twenty years of the 19th century the cases under the Education Acts have increased by 34,000, offences with regard to the highways by 19,000, and offences against local police bye-laws by 56,000.

The best standard—statistically definite and covering a wide area of serious crime—is to be found in the number of indictable offences, *i.e.*, of offences which are triable on indictment, whether actually tried on indictment at assizes and quarter sessions, or disposed of at petty sessions under the extensive summary powers which the magistrates now possess. Within this definition of crime fall not only murder and the great offences against the State, but all crimes of violence except minor assaults, all "crimes against morals," all sorts of forgery and fraud, and all larcenies except some petty thefts. Statistics are available, first of the number of such crimes known to the police, second of the number of persons tried, and third of the number of convictions. Under each of these heads the figures for the period 1880–1900 show a decrease; but the second, the number of persons tried for crimes, is generally regarded as on the whole the best test, and under this head there has been a fall from 60,724 in 1880 to 53,628 in 1900, or, taking the proportion per 100,000 of the population, from 236 to 167.

If the view of crime is extended so as to cover every offence, indictable or otherwise, that can fairly be brought within that designation, including all assaults, all petty thefts, and all minor injuries to property, the number of persons charged fell from 183,000 to 152,500, or, taking again the proportion per 100,000 of population, from 711 to 475. All the figures quoted are those for the years 1880 and 1900. These may be taken as representative years in a progressive series, not seriously influenced by casual variations. If the averages of periods of five or ten years are taken, the results are not affected in any material point. The diminution in indictable offences amounts therefore in twenty years (taking population into account) to a little more than 25 per cent.; but this diminution does not affect all forms of crime equally. The general ratio of decrease applies with little variation to larcenies (which constitute the great bulk—more than five-sixths—of all indictable offences), to robbery, and to forgery. It applies also to crimes of violence to the person, though under some of the most important heads, such as murder and manslaughter, the figures are too small to give any regular rate of progression. It does not apply completely to "crimes against morals," which show an increase chiefly in connexion with the offences created or extended in definition by the Criminal Law Amendment Act, 1885, nor to burglary and house-breaking, which on the whole tended to increase. Offences connected with the coinage, on the other hand, show a much more rapid rate of diminution, having steadily fallen from 311 to 70. Suicide, which appears among indictable offences only in the matter of the attempts, increased steadily, the proceedings for attempted suicide having risen from 74 to 192. In the same period actual suicides increased from 1930 to 2863.

These figures, which apply to England and Wales, though in Scotland and Ireland the tendencies are generally similar, have to be qualified by the consideration of various influences not capable of statistical measurement. Thus the increase in numbers and the improved efficiency of the police, while they are probably one of the causes in the actual decrease of crime, tend to increase the statistics of persons tried by ensuring the detection and punishment of a larger proportion of the offences committed; and the actual decrease in crime is therefore probably somewhat greater than appears from the figures quoted. Again, the shorter sentences now passed on habitual offenders, by giving the same individual more frequent periods of liberty, and therefore more opportunities of committing crime, allow the same person to appear more frequently in the criminal records; and if there has been a diminution in the number of crimes, there is reason to believe that the reduction of the number of persons living by crime is in a somewhat greater ratio. On the other hand, the spirit of leniency towards criminals which now prevails shows itself in a greater reluctance to prosecute for minor offences, and if this influence be taken into account, the estimate of the decrease of crime becomes less favourable.

The causes of the diminution of crime must be found partly in changes in the judicial and penal systems, partly in wider influences affecting the national morals. The gradual extension of the protection afforded by the police to life and property has already been mentioned as one of the influences which have tended to repress crime. Another influence in the same direction has been the extension of the summary jurisdiction of magistrates, particularly in the Summary Jurisdiction Acts of 1879 and 1899. The first effect of the Act of 1879, which much lessened the cost and trouble of criminal proceedings, was to increase the number of prosecutions; but in the long run the greater quickness and certainty of punishment which it secured proved a considerable influence in checking crime. Yet another very important factor was the change of prison organization effected under the Prison Act of 1877, by which the local prisons passed into the charge of a Government department and the varying local methods of treating crime were replaced by a uniform national system. The main features of this system were a severity of discipline for short-sentence prisoners, which, without pretence to reforming efficacy, acted with strong deterrent effect on the minor offenders not hardened to prison life, and the separation of prisoners by cellular confinement, which prevented to a great extent the contamination of first offenders by old criminals. This system has now, under the policy embodied in the Prison Act of 1898, been replaced by one which, while less severe in discipline and allowing more association of prisoners, aims at more complete classification of offenders and greater discrimination in their treatment, and seeks to give more scope to directly reformatory influences. Outside the prison system there has been an extension of the agencies for the assistance or reform of the criminal. The establishment of discharged prisoners' aid societies has been encouraged by the Prison Commissioners, and assisted by Government funds, until their operations now extend to the whole country; while other societies less official in character have shared not less effectively in the same work. Still more important has been the part played by reformatory and industrial schools, which deal with children who are actually criminal or are living in conditions which must inevitably lead to crime. These schools were extensively established before 1880, but dealing as they do with children, they had to exercise their influence on a whole generation before its full effect could be shown in reducing the criminal population.

From a wider point of view the net result of the educative

and social influences at work has been antagonistic to crime, with an increased tendency to meet it rather by preventive reform than by severe repression. The spread of common education and the increase of wholesome literature are powerful factors in this influence, though they have to combat the counter-effects of the debasing literature to which the universal ability to read now gives a wide currency. The teaching of the Churches and of other social institutions has become more practical, and therefore more efficient in the contest with crime, notwithstanding the decay in some directions of religious influences and the weakening of some of the sentiments which support the elementary moral obligations. (C. E. T.)

Drunkenness.

In considering the extent to which intemperance now prevails as compared with former years, the statistics of prosecutions upon which such comparisons are usually based are far from being completely satisfactory, but, inasmuch as they constitute the only possible data for such comparisons, we are compelled to accept them. The following table gives the average number of persons per 1000 of the population proceeded against for drunkenness in England and Wales for each quinquennial period since 1857, the first year of the Judicial Statistics:—

1857–61	4·28
1862–66	4·78
1867–71	5·47
1872–76	7·83
1877–81	7·25
1882–86	6·90
1887–91	6·19
1892–96	5·84
1897–99 (3 years)	6·47
1899	6·74

The figures, it will be seen, show a steady decline from 1872–76 (when the consumption of alcohol was quite abnormal) to 1892–96. Since then, however, the figures have again risen. The increase was especially marked in 1899, when a tide of exceptional prosperity was again accompanied by great drunkenness. It is also disquieting to discover that the average number of prosecutions for drunkenness in the three years 1897–99 was 51 per cent. higher than the average for 1857–61, and 35 per cent. higher than the average for 1862–66. That the increase is partly due to more efficient police administration is probable, but that this is not a complete explanation of the figures is made evident by an analysis of the general statistics of crime during the same period, from which it may be seen that, while crime generally (excluding drunkenness) has decreased 28 per cent. in England and Wales since 1857–61, drunkenness has increased 51 per cent.

Speaking generally, it may be said that drunkenness is chiefly prevalent in the seaport and mining districts. If a line be drawn from the mouth of the Severn to the Wash, it will be found that the "black" counties, without exception, lie to the north-west of this line. The worst counties in England and Wales in the matter of drunkenness are Northumberland, Durham, and Glamorganshire, while Pembrokeshire and Lancashire follow close behind. The most sober counties, on the other hand, are Cambridgeshire, Suffolk, Oxfordshire, and Wiltshire. Averages based upon the returns of entire counties do not, however, afford a complete guide to the distribution of drunkenness, inasmuch as offences are not equally distributed over the whole area of a county. A heavy ratio of drunkenness in a small district may often give a county an unfavourable position in the general averages, notwithstanding favourable conditions in the rest of its area. A better classification is that adopted by the compiler of the Judicial (Criminal) Statistics for 1898, and represented in the following table:—

	Drunkenness (No. of prosecutions in 1898) per 1000 population.
Mining counties	11·19
Seaports	10·20
Metropolis	9·94
Manufacturing towns	5·58
Pleasure towns	5·87
Agricultural counties—	
South-western counties	2·84
Home counties	2·63
Eastern counties	1·23
England and Wales	6·98

Further analysis of the prosecutions for drunkenness shows that about 24 per cent. of the total number of offences are committed by women. In the larger towns the proportion, as a rule, is higher. In London, 38 per cent. of the drunkenness is attributable to women; in Manchester, 36 per cent.; in Belfast and Glasgow, 32 per cent. In Liverpool, on the other hand, the proportion is only 24 per cent. The much-controverted question as to whether intemperance is increasing among women can hardly, however, be decided by an appeal to the criminal statistics. So far as these statistics throw any light at all upon the question, they suggest important local differences. A more direct clue is afforded by the Registrar-General's annual returns of deaths directly attributed to intemperance. The figures are given below. In order to eliminate accidental variations, the comparison is based upon the average mortality during consecutive quinquennial periods:—

Quinquennial Period.	Average No. of deaths (England and Wales).	Males per cent.	Females per cent.
1877–81	1071	69	31
1882–86	1320	66	34
1887–91	1710	64	36
1892–96	2044	61	39
1897–99	2577	61	39
1899	2871	60	40

The figures are certainly striking. They show, it will be noticed, that out of every 100 deaths from alcoholic excess in England and Wales at the present time women contribute nine more than they did in 1880. If, instead of taking the total number of deaths, we take the ratio per million persons living, the increase is seen even more clearly:—

	Males per million living.	Females per million living.
1877–81	60	25
1882–86	67	32
1887–91	79	42
1892–96	86	51
1897–99	103	63
1899	112	70

It appears that, while the ratio of mortality from alcoholic excess has increased 87 per cent. among males during the last twenty years of the century, among females it has increased by no less than 180 per cent.

Despite the strenuous and, in many respects, successful efforts of temperance reformers, the consumption of alcohol per head in the United Kingdom has, though subject to fluctuations, increased until it was greater in 1902 than it was in 1840, when the temperance reformation was in its infancy. The consumption per head of alcoholic liquor in the United Kingdom in 1840, as compared with 1900, was as follows:—

	1840 (Gallons).	1900 (Gallons).
Spirits (proof)	0·97	1·12
Wine	0·25	0·39
Beer	28·59	31·75

If the figures are reduced to a basis of proof spirit,[1] the result is as follows :—

	Gallons.
1840 consumption per head	3·89
1900 ,, ,,	4·40

To adopt a familiar method of comparison, the expenditure per head of the population upon alcoholic drinks was in 1840 £2, 18s. 10d., and in 1900 £3, 18s. 8d.

That this increase in consumption is not due to the selection of exceptional years will be seen from the subjoined table :—

Years.	Equivalent in Proof Spirit (Gallons).
1841–45	3·36
1846–50	3·58
1851–55	3·75
1856–60	3·56
1861–65	3·60
1866–70	4·09
1871–75	4·78
1876–80	4·70
1881–85	3·90
1886–90	3·87
1891–95	4·08
1896	4·20
1897	4·28
1898	4·30
1899	4·48
1900	4·40

It will thus be seen that the increase in the consumption of alcohol per head from 1841–45 to 1891–95 amounted to nearly three-fourths of a gallon of proof spirit. The highest figures were reached in 1876 (when the effects of the great wave of commercial prosperity which marked the 'seventies were at their height), when the consumption per head rose to 4·89 gallons of proof spirit. With the subsidence of the commercial "boom" the consumption at once declined, but only to a point that was still slightly above what may be called the normal figures of the ante-1870 period. During the decade 1889–99, however, they rose again steadily, until the consumption in 1899 was higher than it had been for a period of twenty-one years.

That much of the indulgence in alcoholic drinks is excessive and wasteful is not seriously disputed. Opinions, it is true, differ as to the proportion of the total consumption that may be so regarded, and the amount at best can only be approximately determined, but even at the lowest computation it certainly forms a not inconsiderable proportion of the whole. Professor Leone Levi, in his evidence before the Lords' Committee in 1877, estimated the amount of intemperate consumption at one-fifth of the total consumption. Mr Dudley Baxter's estimate is very much higher than this. The figures which he gives for 1869 show that 38 per cent. of the total consumption of spirits and 32 per cent. of the total consumption of beer must in that year have represented intemperate consumption. If we make the most liberal allowance for a more general diffusion of wealth and a consequent increase in the amount of temperate consumption in the interval, and reduce the proportions which Mr Baxter gives to 30 per cent. and 25 per cent. respectively, it would follow that more than £39,000,000 was spent in 1900 in intemperate and wasteful drinking.

The number of public-houses and beer-shops has, it is true, been steadily declining, no fewer than 10,000 having disappeared between 1876 and 1896; but this reduction in numbers has been more than out-balanced by the reconstruction and enlargement of those that remain. The reduction in numbers has affected, for the most part, the smaller and least profitable houses only; but these have been largely replaced by huge "gin-palaces," so that what Lord Randolph Churchill called the "fatal facility of the public-house" has become a more serious social fact than was the case in 1875. In important legislation the last twenty years of the 19th century showed little progress.

Important licensing proposals were made by a Conservative administration in 1888 and 1890, and by a Liberal administration in 1893 and 1895, but in each case they failed to become law. The following is a summary of temperance legislation since 1880 :—

1881. Welsh Sunday Closing Act.
1883. Acts prohibiting the payment of wages in public-houses, and the use of drink-shops or refreshment-houses for parliamentary election meetings.
1884. Municipal Elections Corrupt Practices Act, prohibiting use of public-houses and refreshment-rooms for committee purposes or meetings in connexion with municipal elections.
1886. Intoxicating Liquor (Sale to Children) Bill, prohibiting sale of intoxicants "for his or her own consumption" to children under thirteen.
1887. Beer and Cider Truck Clause, prohibiting the furnishing of beer, cider, &c., to agricultural labourers as part payment of wages.
Also Scottish Early Closing of Public-houses Act, giving discretionary power to licensing benches outside burghs of 50,000 inhabitants to close public-houses one hour earlier on week-nights.
1888. Habitual Drunkards Act.
1894. Prevention of Cruelty to Children Act, which, *inter alia*, empowers magistrates to commit to inebriate homes the drunken parents of ill-used children.
1897. Licensing Amendment (Scotland) Act.
1898. Habitual Inebriates Act.
1900. Beer Retailers' and Spirit Grocers' Retail Licences (Ireland) Act.
1901. Intoxicating Liquors (Sale to Children) Act. (A. SH.)

FOOD.

The abolition of duties, the invention of cold storage, the practice of tinning meat and fruits, and improved means of transit, have enlarged the supply and changed the character of the foods of the people. Casual observation of the shops in poor neighbourhoods shows the tins of salmon, peaches, soups, as well as of ordinary meats, piled up for sale, while on the barrows in the streets there is a plentiful supply of bananas, tomatoes, grapes, &c. Closer inquiry confirms the conclusion suggested by such observation. In 1883 there was imported and retained for home consumption 0·75 ℔ of fresh mutton per head of the total population of the United Kingdom; in 1900 the amount had risen to 9·28 ℔. The figures with regard to bacon and ham show that in 1883 there was 11·01 ℔ imported for each inhabitant, while in 1900 the amount was 19·62 ℔. There is a like increase in the use of imported butter. In 1886—the first year in which it was distinguished—4·57 ℔ per head was imported; in 1900 the amount was 9·11 ℔. In 1883 each person had for his use 26·52 imported eggs; in 1900 he had 49·48. But the most astonishing increase of all, representing the development of the use of jam, is in sugar. In 1883 the import of sugar for home consumption per head of the population was 9·91 ℔ of refined sugar; in 1900 it was 52·23 ℔. It is somewhat more difficult to tell by figures the development of the use of foreign fruits; they were not distinguished in the returns till 1892, but in that year the value of grapes imported was £363,644, and in 1900 the value was £595,000. The dried or tinned fruits imported in 1883 were of the value of £809,938, and in 1900 the value had risen to £1,848,872, an astonishing increase, justifying the conclusion drawn from the tins which fill so many shop windows. It must be remembered that these figures take no account of the home produce,

[1] The Spirits (Strength Ascertainment) Act, 1818 (58 Geo. III. c. 28), defines "proof spirit" to be that which, at a temperature of 51°, weighs $\frac{12}{13}$ parts of an equal measure of distilled water. A gallon of proof spirit contains 57 per cent. of alcohol. The calculation is made on the ordinary basis that wine contains 30 per cent. and beer 10 per cent. of proof spirit.

which must be added to the food supply of the people. If, now, the further question be asked, whether the increased importation has been followed by a decrease in price, the answer is generally in the affirmative. A live ox which was valued at £21·57 in 1883 is valued at £18·19 in 1900; a sheep has gone down from 45·13 shillings in 1883 to 31·87 shillings in 1900. Flour of wheat which was 15·12 shillings per cwt. in 1883 was 9·38 shillings in 1900. Food may therefore be said to be cheaper, more plentiful, and more varied. It is also more closely protected. The Food and Drugs Act, 1875, amended in 1899, aims to protect consumers against adulteration in all its recognizable forms. The Weights and Measures Act, 1878, was amended in 1899, so that local authorities might have more power to enforce its measures. Under these Acts armies of inspectors are always at work. They every year condemn as unwholesome tons of fish, meat, and fruit, and they every week prosecute sellers whose weights and measures have been found to be short. The presence and activity of these inspectors have created a standard up to which public opinion slowly rises, so that there is now greater care on the part of purchasers to avoid bad food. The review of the food supply of the people is so far encouraging. It may be that in developing foreign supplies the home supply has been neglected; that for want of skill gardening near the great towns has not been developed, that by the monopoly of railways the transit from country districts has been made difficult; it may be that food might be fresher and even cheaper; but measured by any test, the advance during the period 1880–1900 was great. There is, however, another set of facts which have to be considered. Casual observers not only see loaded shops and stalls: they see also many poorly-nourished faces and poorly-developed bodies among the people who crowd the streets; they not only hear of increased imports: they also hear from doctors that the diseases of the poor are largely due to underfeeding. Students who look more closely find that for the bare support of life a man in moderate work requires daily 3500 calories of food energy, and a woman eight-tenths of this amount. It is according to this scale that the Local Government Board has framed the dietaries for use in workhouses. Careful inquiry has shown that to provide this amount of food in the cheapest form, without regard to taste, the cost for a man per week is 3s. 3d., for a woman 2s. 9d., for children 2s. 3d. A family, therefore, of five persons would need at least an income of 22s. a week just for rent, clothing, and food, without any margin for drink, holidays, literature, or amusement. The statement of this fact is sufficient to prove that even with this supply of food there must be a large number of people still underfed. Mr Booth and Mr Rowntree, who have made detailed inquiries, both agree that 30 per cent. of the people live in poverty, nearly half of them because of an insufficient income, and the rest because of their ignorance, their wastefulness, or drinking habits. If in a family where the earnings are 22s. or 24s. a week the man falls ill or gets out of work, if a holiday is taken, if a treat be indulged in, if even some food be bought more appetizing but less nutritious than that which has the largest strength-giving power, if there be any change in the ordinary routine—then the necessary food must be reduced and the body be called on to suffer. There are notoriously many families where the income is below 22s. a week; there are at least an equal number of families where, if the earnings be somewhat larger, there is ignorance as to the right choice or use of food, and great waste of substance on drink and amusements.

The conclusion of Mr Booth and Mr Rowntree is, therefore, that 30 per cent. of the population is underfed. The remedy is, first of all, an increase of wages, which means that by intelligence and character the worker shall be worth more wages. But with increased wages there must be also increased knowledge of the value of foods and of the methods of feeding. Mothers frequently give their children meat before the appearance of teeth with which to bite it. Wives prepare their husbands' meals in such a way as to destroy much of their nourishing power. People have often altogether wrong notions as to what is strengthening and what is not. It is something that these facts are known, and already local authorities have started lectures and cookery classes, which ought to be valuable.

(H. O. B.; S. A. B.)

Health.

Examination of the death statistics shows a steadily increasing average length of life in England. The "expectation of life" at birth, which in 1880 was calculated to be 41·35 years for males and 44·62 years for females, had increased ten years later to 43·66 years and 47·18 years respectively. Thus the average length of life in England in ten years increased by about three years, and is still increasing. We find that the decrease in the mortality is still apparent at all ages from 1 year up to 45 years among males and to 55 years among females. The mortality has increased at other ages up to 85 years, after which there is an apparent decrease. From the ages of 5 years to 30 years the decrease in the rate of mortality is relatively large, and, though less marked, the decrease is evident also in all the succeeding age-periods.

But while we recognize the general improvement in the conditions of life, further examination indicates considerations of a less satisfactory nature. There is still a high death-rate among infants under 1 year of age, though this decreased during the period under review. Dr Farr, whose studies of vital statistics have served—and still serve—as models for other workers in this field, mentioned the following conditions as those the influence of which on the health of a community is unquestionable:—(1) the physical well-being of the people as to dwellings, food, drink in excess or defect; (2) firing; (3) cleanliness and clothing; (4) sewage and drainage. The relation between health and the density of population under existing sanitary conditions, and the measures taken to limit the spread of infectious diseases, have also to be taken into consideration. Some of these conditions are under the control of the individual, others are regulated by the State or by local authorities. There are facts to be elicited from the tables of the causes of death which appear to indicate that the improvement in the healthiness of the people is due not so much to a greater attention to health requirements by individuals, as to the sanitary improvements carried out by local authorities and the health regulations initiated or enforced by the State. The regulation of the conditions of labour by the Factory Acts, &c., has tended to reduce the mortality in certain trades and occupations. Without going into detail, the general result is shown by the fact that comparison of 1891 with 1871, with regard to 76 occupation groups where such comparison is possible, shows that at the ages 25–45 (which corresponds with the working period of life) there was decreased mortality in 63 of these groups, during the latter period, whilst in 13 groups only was there an increased mortality. The deaths from zymotic diseases show a diminution, especially in those diseases which are influenced by the sanitation of towns or districts, and those for the prevention of which special regulations are in force. Enteric fever and diarrhœa, the spread of which depends so largely upon drainage and water-supply, are credited with a decreasing death-rate. The mortality from scarlet fever shows a large diminution, and whooping

cough also is less fatal. Measles remains a frequent cause of death, and the mortality from this cause, though diminishing, fluctuated but little during the last thirty years of the 19th century. Diphtheria has increased, and shows a progressive increase in mortality. This disease is especially fatal in young children at an age when isolation is impracticable, and the mortality from this cause may be taken as to some extent a measure of the sanitation of the home as distinct from the sanitation of the locality. There is still much room for improvement in the sanitation of the homes of the poor especially, and in the care which would prevent the spread of infectious illness in the family. The diminution in the mortality from consumption and other tubercular diseases is one of the most noticeable and at the same time satisfactory facts which the death returns demonstrate. This decreased mortality can only be referred to an improvement in the general sanitary and hygienic condition of the people, for as yet it can hardly be said that any special preventive measures have been put in force against these diseases. The influence of overcrowding—the aggregation of individuals —in the causation of consumption is undoubted. The efforts made by the authorities in most towns to prevent the overcrowding, both of buildings on a given area and of inhabitants within the dwellings, have probably had an important influence in the decrease of consumption. But we may reasonably assume that some proportion of this decrease indicates an improvement in the dwellings of the people, and is a sign of increased prosperity. This assumption is borne out by the fact that, although the diminution in the mortality from consumption is to be observed at all age-periods and in both sexes, it is in the earlier stages of life more especially that the reduction has taken place, and the decrease has been greater amongst females than amongst males in the later age-periods. We may take the changes in the death-rate from phthisis (consumption) in children under 15 years of age, and in women, to represent the influence of the home conditions, for these are much at home, whilst the men are subject to outside influences at their work. In illustration we may take from the sixtieth report of the Registrar-General (1897) the following figures, which show the percentage reduction in the phthisis mortality between the period 1861–70 and that of 1891–97 :—

Age Groups.	Reduction per cent. in 1891-97.	
	Males.	Females.
All ages	35	49
Under 5 yrs.	55	58
5	58	49
10	60	50
15	53	56
20	49	57
25	39	53
35	23	42

The reduction, which is considerable for both sexes up to the age of 15, becomes proportionately greater for females as compared with that of males in the succeeding age-periods.

But while we recognize with satisfaction such indications of improvement in the well-being of the people, we have on the other hand to note that the death-rates from anæmia, from rickets, and from diarrhœa show an increase. These diseases are to a large extent dependent upon the hygienic conditions of the home life. There are other considerations also which call for serious attention as indicating evils of national importance. The high mortality of men of all ages after 25 years is especially remarkable in London, whilst the mortality of women is increased to nothing like the same extent. Two causes appear to operate powerfully in producing this result. The first of these is referred to by Dr Farr in these words :—"Not only the roughs but the intelligent artisans of London do not wash the whole of the body daily." The second cause is, in the opinion of the same authority, the greater intemperance in regard to alcohol of the men as compared with women.

The influence of occupation is also seen to be very great, for those most exposed to temptation show the highest death-rate. Innkeepers and inn servants, and those engaged in the manufacture of alcoholic beverages, show the greatest mortality; cab and omnibus servants, costermongers, commercial travellers, come close upon these; and butchers and bakers are also high on the list. It is a significant fact that while the drivers, &c., of cabs and omnibuses show a high mortality from intemperance, engine drivers and railway guards come low on the list of deaths from alcohol; these men have, for the most part, responsible and well-paid posts, which they could not retain if they were intemperate. The death-rate from insanity and that from suicide show a progressive increase. It is notable that those occupations which show a high mortality from alcoholic excess furnish also the highest proportionate mortality from suicide. It is therefore permissible to attribute some portion at least of the increased mortality from insanity to the greater prevalence of intemperance. There remains the fact that the mental strain resulting from the greater competition of the present day may have some influence on this mortality from mental disease, which thus represents the price the community pays for its prosperity. The continued increase in the mortality from diabetes points also to the severity of competition, since nervous strain and worry are important factors in the causation of this disease.

The conditions of life in towns contrast most unfavourably with those of rural districts. The urban death-rate in 1899 was equal to 19·2 per 1000, while the rural rate was 16·3 per 1000. And although the urban rate was equal to the average of the ten preceding years, the ratio of urban to rural mortality (as 118 is to 100) is higher than the average ratio during those ten years. It is abundantly evident from the returns of the Registrar-General that the death-rate of different districts increases according to the density of the population, *i.e.*, the number of persons to a given area. There is a tendency for the people to leave the country districts and flock to the towns, where work is, as a rule, more highly paid and perhaps more plentiful. But though this may lead to the greater prosperity of the individuals, it has an injurious influence on health. And since it is the children who are particularly susceptible to those conditions which make the towns less healthy than the rural districts, it is evidently desirable that so far as possible the families of the town workers should be brought up in the country, or at least on the outskirts of the town rather than in its crowded centre. (J. E. S.)

Holidays.

Holidays have been greatly extended since 1875, and signs of the change are everywhere manifest. Almost all persons in regular employment now stipulate for a holiday period, and employers have to arrange accordingly. The Bank Holidays Act, 1871, expressed the tendency of the time, and gave it great impetus. People who had hitherto taken casual holidays, and perhaps felt somewhat conscience-stricken at neglecting work, now felt justified, and began to plan the use of these days. The railways and caterers for amusement have of course risen to the occasion, and tempting advertisements crowd the walls.

The effect of the Act has been to stimulate the holiday sense and awaken the dormant curiosity of many a mental sleeper. The offer of a whole day has encouraged enterprise in those who hitherto had spent their broken bits of holiday within a few yards of their homes, and it has led those who have learnt to enjoy one day to demand a longer season. But it is a question whether this Act has not now answered its purpose. Enormous crowds of people composed of one social class generate excitement which is unwholesome, the great demand on space in carriages or in places of resort brings about a rise of prices, and there is often a laxity of manner and of morals, followed by incidents which are demoralizing. Many thoughtful members of the industrial classes now hold the opinion that the existence of the Act makes their demand for periodical recreation less effective, and has set apart days on which the lower classes revel and the upper classes remain indoors. "A chasm," they say, "has been made between classes who would have been better for taking their pleasures in relation to one another." The fact, however, remains that bank holidays, and especially the August holiday, are a great institution. They have become the centre of longer holidays, the day necessarily included in the week or fortnight. They draw out vast crowds to places of amusement or to country resorts. The tendency every year is for people to go farther afield and to make more use of the railways. The Crystal Palace, for instance, is more, and the Zoological Gardens less frequented. The railways and steamers are every year more largely used for excursions to more distant counties or seaside places. The habit of travelling has indeed enormously developed. In consequence, there has been a great increase of agencies and facilities, some of which are educational and some simply commercial. Of the latter Messrs Cook have been the pioneers, and now there are various firms who render travelling easy in all parts of the world, by providing couriers and hotels, as well as personal conductors. Of the former the Toynbee Hall Travelling Club is the original on which many others have since been formed. In these clubs the members are instructed, before their journeys, in the history, art, &c., of the countries they visit, or they are accompanied by lecturers, who on the spot tell something of the things and people around.

It is impossible to give any idea of the numbers who make use of either of these agencies, but the presence of English people is very evident to all travellers abroad. In the British Islands the railways and steamers have made travelling easier and cheaper. Third-class carriages are attached to express trains, and on some lines accompanied by refreshment cars. The carriages themselves have been made more comfortable, and access to distant places has been opened. In 1877 the total length of lines open in the United Kingdom was 17,077 miles. In 1900 it had increased to 21,855 miles. In the earlier year the number of passengers (exclusive of season ticket holders) carried was 549,541,325, and in 1900 the total reached was 1,142,276,686, who paid as fares £45,383,988, against £26,534,110 paid in 1877. The reduction in the fares by means of excursion and tourist tickets is shown by the fact that while the passenger traffic has doubled, the amount for conveying them each mile has only increased by one-eighth. Two persons could in 1902 travel for 8d. the same distance as in 1877 one person was conveyed for 7d. These increased facilities for travel have been followed by the increase of places of resort, especially on the coast. A plan for opening more remote country districts has been adopted by the railway companies, who issue at the beginning of each season lists of lodgings at farmhouses, cottages, or moorland homesteads. The children's country holiday funds, followed by the women's and factory girls' clubs, have largely increased the summer exodus from town to the country. By means of these funds the children and the women paying something for themselves are placed for a week or fortnight in country cottages. They get by this means not only change of air and food, but some experience in the habits of country people and country animals. The numbers who are thus sent from each city are very large; 50,000 at least go annually from London in connexion with the funds, and an uncounted number who, having once been by the help of the fund, now make their private arrangements. But it is not only the railways and steamers which have enabled people to get the pleasures of change: the invention and the improvement of the cycle has put much new pleasure within the common reach. In 1878 the Cyclists' Touring Club was formed, with 144 members: in 1900 it had a membership of over 50,000; and, still more recently, motor-cars have offered themselves as new means of locomotion. Increased holidays constitute perhaps the most marked feature of the years since 1875. The feature is due to many causes; but it is to be noted that in 1842 the Early Closing Association commenced its agitation, and has never since ceased. Its object was a half-holiday for every person employed in shops. Its own object has not been reached, and Sir John Lubbock (Lord Avebury) has vainly striven to secure by law what the association has failed to secure by voluntary action. If, however, the association has not reached its object, its influence has undoubtedly been instrumental in educating public opinion.

A review of the whole subject is encouraging. There may still be whole classes whose holidays are uncertain; there may be even larger classes who can never look forward to periods longer than one or two days; there may be some misuse of holidays; but, on the whole, times of leisure are more regularly provided, and are used in getting strength and knowledge. If sometimes it seems as if love of pleasure had become excessive, and that men hurried work so as to get to play, there must be patience over times of transition. It is good that people have time to travel, to get fresh air, and to know one another; if they do not at once use the time for the best purposes, it is something that they have the time to use.

The chief criticisms which it occurs to the writers to make are: (1) that it would be better if holidays were spread over the year, and not so generally confined to the month of August; (2) that the practice which now holds of giving clerks a holiday of weeks should be extended to workmen who now take holidays of days, which in the year often amount to weeks; and (3) that education should be directed to fit people to enjoy themselves in natural surroundings, rather than depend on getting enjoyment from excitement. (H. O. B.; S. A. B.)

Open Spaces.

Since 1847 many Acts have been passed relating wholly or partly to the provision of open spaces, besides those which were framed to deal with special parks and recreation grounds. Section 164 of the Public Health Act, 1875, provided for the acquisition of such spaces; the Commons Acts of 1866 and 1876 secured the preservation from encroachment of lands over which there were public rights; the Open Spaces Acts of 1877, 1881, and 1887 gave further powers to local sanitary authorities to utilize, acquire, and maintain recreation grounds; and the Disused Burial Grounds Act of 1884, by making it illegal to build on any land that had been set aside for interments, assisted the movement, begun in London in 1875, to convert the old closed graveyards into public gardens. A valuable impetus was afforded by the Corporation of London (Open

Spaces) Act, 1878, whereby the Corporation was empowered to levy a tax on grain, and to use the money for the acquisition of public land outside the metropolis, such as Epping Forest, with its area of over 5000 acres. In order to stimulate and encourage the efforts of the public bodies, and to watch the progress of open space legislation, certain useful voluntary agencies came into existence. The Commons Preservation Society has worked most assiduously since 1865 (see COMMONS). The Metropolitan Public Gardens Association, formed in 1882 by the earl of Meath, has carried through, or assisted to carry through, nearly 500 successful undertakings. Open space agencies have been started in Glasgow, Liverpool, Manchester, Norwich, and other provincial towns, in the colonies, in America, and on the Continent; while a sub-committee of the Kyrle Society, under Miss Octavia Hill, has done very useful work. This valuable movement has also from time to time been encouraged by noble gifts of parks and other lands for the use of the public. A joint committee of representatives of the open space societies, presided over by Lord Hobhouse, urged all public governing bodies throughout the kingdom to commemorate the Diamond Jubilee by carrying out some open space scheme; and this Queen's Commemoration Committee reported that 78 such schemes had been carried through to their knowledge, 9 being in London and the suburbs, and 69 in the provinces, resulting in a gain of 651 acres (besides trees and seats), of which 160 acres appeared to have been given and 491 purchased. By the Commons Act of 1899 the county councils acquired the same powers as had before then belonged to the urban and rural district councils, and all these bodies can now preserve, purchase, lay out, or maintain recreation grounds.

The following works on this subject will be found useful:—SHAW LEFEVRE. *English Commons and Forests.*—Sir R. HUNTER. *Open Spaces, Footpaths, and Rights-of-Way.*—Mrs BASIL HOLMES. *The London Burial-Grounds.*—Colonel SEXBY. *The Municipal Parks and Gardens of London.* (I. M. H.)

PUBLIC LIBRARIES.

In 1875 only 82 towns or districts in the United Kingdom had adopted the Public Libraries Acts; and in this number centres of population like London, Glasgow, Preston, Portsmouth, Aberdeen, Edinburgh, Halifax, Belfast, Croydon, West Ham, and Huddersfield were unrepresented. Now every large town in the country has its public library, and not a few of the smaller urban and rural districts. In all, 430 places had established libraries up to the end of 1901, and it is estimated that these institutions are the means of circulating about 40,000,000 volumes of carefully selected literature every year. These issues represent but a tithe of the work actually accomplished by the public libraries of the country, because the total only includes books issued for home reading and books which are referred to in reading-rooms and duly recorded. The immense number of unrecorded references made to commercial, technical, and literary works, which most libraries now place for free inspection on open shelves, are not counted in this estimate, nor does it include the enormous use of artistic, literary, scientific, trade, and other magazines or journals, made by all classes of people, not to speak of the newspapers and miscellanies. Other departments of work which have been undertaken by library authorities, such as lecture courses, classes, museums, juvenile and school libraries, &c., have also to be reckoned as additions to the extraordinary range of activity already indicated. In one respect the public libraries of the present day compare very favourably with those of 1875, and that is as regards general excellence of administration. Scientific methods of arranging and cataloguing books, so as to make them easily accessible to all, had not been devised or widely adopted in the past; and though a considerable number of libraries still lag behind as regards close classification, the cataloguing has improved greatly, and it is now very rarely that a really bad catalogue is published. In other respects improvements have manifested themselves. Greater freedom is now allowed to readers, and restrictive rules and regulations have been relaxed with benefit to all concerned. Some libraries have adopted, with complete success, improved methods of allowing borrowers direct access to the shelves, there to select books by actual examination and comparison in minutely classified libraries, and the result of seven years' experience has been to justify what was regarded as a somewhat dangerous departure. Mr James D. Brown, the librarian of the Finsbury Public Libraries, was the first to initiate this system for lending libraries, and his name will ever be associated with open access to the library shelves. Other libraries, by reducing the age limits at which readers may enter, and otherwise extending the franchise, have not only increased their popularity, but largely extended their spheres of work and usefulness. The funds for carrying out the great variety of work undertaken by public libraries remain the same now as in former years, and with few exceptions no further power has been granted since the penny limit to the rate was fixed in 1855. Some few towns which have secured special legislation have been enabled to raise the amount of rate, or even to abolish the penny limitation, and have thus achieved results in advance of their neighbours. But it is quite clear that until Parliament steps in and empowers local authorities to increase the library rate by a general abolition of the old limit, or fixing a new and higher one, the majority of British public libraries will have to struggle on as best they may—in a healthy but somewhat crippled state. The conditions under which the Acts may be adopted by a community have been greatly simplified by the Public Libraries Amendment Acts, 1893 and 1901, and the London Government Act, 1899. The power of adoption has been transferred from the ratepayers at large to the governing body of the administrative area, saving as regards parish councils, and the result of this transfer has been a large increase in the number of public libraries.

Reference may be made to some of the recent literature on the subject, which has not only improved in quality and increased in quantity since 1875, but is much better represented both in journals and books. For recent statistics, methods of work, &c., see GREENWOOD'S *Library Year-Book*, 1897 and 1900–1. The history of the movement is told at considerable length in THOMAS GREENWOOD'S *Public Libraries*, 4th and 5th editions, and OGLE'S *The Free Library*, 1897. Other aspects of the subject may be studied in the various volumes of *The Library Series* edited by Dr GARNETT; *Manuel de Bibliothéconomie*, by GRAESEL and LAUDE, 1897 (a good general sketch of methods); *A Library Primer*, by J. C. DANA; the publications of the Library Association; the *Library Association Year-Book;* and the current British and American journals devoted to librarianship. (T. GD.)

WAGES AND HOURS OF LABOUR.

Since the formation of the Labour Department of the Board of Trade in 1893, the wages statistics of the country have steadily increased in value and in volume; but the complexity and variety of the wage-earning classes, the limited extent to which representative returns can be obtained, the irregularity of employment, the prevalence of overtime, and the differences in the methods of remuneration—all of which obscure the definiteness and detract from the sufficiency of such returns as are available—are among the causes that make any general statement as to rates of wages and average earnings impossible. Certain general tendencies at the end of the 19th century may, however, be indicated. First, as to the distribution of the wage-earning classes. The diminishing proportion of

the population of the United Kingdom that is engaged in agriculture is one of the salient facts of the century. In 1825 the amount of agricultural and of non-agricultural labour in Great Britain was approximately equal. In 1891 the ratio was about one to five, the totals for the chief agricultural classes having fallen in England and Wales during the decade 1881–91 from about 1,135,000 to about 1,050,000, while the total population of the country was steadily increasing. The general, though by no means the unbroken, tendency has been for wages to increase since 1880, those of agricultural labour having perhaps increased most slowly, and chiefly towards the end of the period, so that the importance of the above figures becomes more manifest. The most notable increases in the occupation returns for England and Wales in the years 1881–91 are shown by coal-miners, railway and general transport employees, machine and boiler makers, and printers, their rates of increase being respectively 84, 78, 24, and 14 to every 10,000 males of ten years and upwards in the country, and their aggregate mounting in the ten years from about 1,060,000 to about 1,400,000.

The general course of trade and employment during the last twenty years of the 19th century may be briefly described as follows. The first of the two decades opened after a period of depression (the reaction from the inflation of the years 1871–74), which had reached its lowest point in 1879. From 1880 to 1883 came a time of expanding trade, checked at the end for two or three years, but afterwards recovering and again expanding until 1891. In the period of decline which then began, 1893–94 marks the lowest point; but from that year until 1900 expansion again took place. During 1900, which had opened with employment still in full flood, and with wages still tending upwards, a slight reaction followed on the prosperity of the preceding six years. There was, however, no general contraction in the demand for labour, and such falling-off in wages as ensued (up to the beginning of 1902) was gradual in character and limited in scope, affecting mainly the mining and metal industries. The knowledge, however, that employment was good in certain years, or that wages tended to rise or fall in such and such a period, has little significance if we remain ignorant as to any movement that may also have taken place in the prices of those commodities on which wages are to a great extent expended: it is necessary to take into account the distinction between real and nominal wages. With the exception of 1889–91 and 1898–1900, the trend of wholesale prices was almost continuously downwards during the period 1880–1900. The influence of this decline upon the cost of living has been sometimes exaggerated, but at no time was there a greater variety of commodities purchasable by the masses of the people of the United Kingdom than at the close of the 19th century; and owing to the continued improvement in methods of production and in facilities for transport, although special classes of workers suffer from the changes and dislocation that even improvements bring, the general course of the markets is still in favour of the working-class consumer. The statistics of consumption of many of the necessaries of life illustrate this development, but perhaps still more significant is the gradual transition of many "luxuries" into the class of "necessaries," due to the gradual rising of the standard of comfort, and thus to the widening of the area of demand. It is no longer possible to find an index of well-being, even among the poorer classes of the community, in the price of the quartern loaf. The most important item in working-class expenditure, which has neither contracted nor even remained stationary, has been house rent. In many rural districts there are well-founded complaints of the low standard and the insufficiency of the accommodation available, and these complaints are echoed and emphasized in towns owing to the increasing rents that have to be paid. Although the expense of "housing" is thus often an increasing charge upon wages, the healthiness and conveniences of dwellings are also often increasing, both through the competition of owners and through the exercise of greater administrative care. It cannot, therefore, be asserted, without qualification, that even as regards rent charges real wages are declining. In many great centres of population, moreover, the problem of housing is being met to a growing and an unforeseen extent by the provision of greater facilities for locomotion. The census returns for London in 1901 reflected these various influences, showing as they did that the larger tenements had increased during the decade twice as quickly as the smaller ones, and that the one-room tenements had declined during the same period from 172,502 to 149,524.

Meanwhile, the population of the country has increased, the general health of the community has improved, the average age at death has risen, and there are many additional proofs that there is a considerable net increase in earnings. The following table will illustrate several of the points to which reference has been made:—

Year.	Proportion of Total of Imports and Exports per Head of Population of United Kingdom.	Index Numbers (Sauerbeck's) showing Variation in Wholesale Prices (1867–77=100).		Prices—			Consumption per Head of Population of United Kingdom.			Post Office Savings Bank.	
				Of Bacon imported (per cwt.).	Of Tea (per lb).	Of Tobacco, unmanufactured (per lb).	Bacon and Hams, imported.	Tea.	Tobacco.	Amounts due to Depositors in United Kingdom.	No. of Accounts open at End of Year.
	£ s. d.	Food.	Total.	s. d.	d.	d.	lb.	lb.	lb.	£1000.	000's.
1881	19 17 2	91	85	45 10	12·82	6·85	13·92	4·58	1·41	36,194	2607
1886	19 17 0	72	69	37 9	11·77	7·23	12·98	4·92	1·44	50,874	3731
1891	19 14 0	77	72	37 10	10·70	8·60	13·11	5·36	1·61	71,608	5118
1896	18 14 1	62	61	34 6	9·55	6·02	16·90	5·77	1·73	108,098	6961
1900	21 9 0	60	75	41 9	8·58	7·16	19·02	6·11	1·96	135,549	8439

The following table has been compiled from the 1900 report of the Labour Department on changes in rates of wages in the United Kingdom:—

Changes in Rates of Wages.

Years.	Trades.	Gross Aggregate Nos. of Individuals Affected.		Total Amount of Changes per Week.	
		Increases.	Decreases.	Increases.	Decreases.
				£ s.	£ s.
1893–97	Building	209,207	4,646	25,160 5	273 5
"	Mining and quarrying	441,693	1,003,426	27,559 14	99,221 19
"	Metal, engineering, and shipbuilding	459,808	181,905	36,521 10	11,921 17
1898–1900	Building	210,830	8,097	21,929 14	191 4
"	Mining and quarrying	2,041,012	4,018	290,457 6	294 6
"	Metal, engineering, and shipbuilding	456,768	10,642	50,378 13	1,292 17
1893–97	All trades[1]	1,340,778	1,277,937	103,395 16	106,172 5
1898–1900	All trades[1]	3,290,418	36,097	364,[illegible] 0	3,712 13

[1] Exclusive of agricultural labourers, railway servants, and seamen.

The net result per head of all the changes recorded in the above table in the years 1893–97 is practically *nil*, the figures showing a decrease of only a fraction of a penny per head per week of all persons affected. During the years 1898–1900, on the other hand, the total weekly advances were considerable, being equivalent in the aggregate, and assuming regular employment, to an

increase of nearly £20,000,000 in the yearly wages bill of the United Kingdom. During 1901 there was a slight set-back from the conditions of exceptional and in some directions inflated prosperity of the early months of 1900.

The figures relating to the hours of labour tell of a much more continuous movement than do those relating to wages, and show that for the organized trades of the country the recognized working week is getting steadily shorter. From the Parliamentary Return (1890) giving "the average number of hours worked as a week's work in the chief trade centres" in the years 1850, 1860, 1870, 1880, and 1890, we find, on analysis of the 1121 returns (962 from employers and 159 from trade unions), that in 1890, as compared with 1880, there were only 73 cases of a lengthened working week, as compared with 363 cases in which it was shortened. Of the 73 cases, 56 are reported from various branches of the building trades. The value of these returns is considerably diminished by the omission of all numbers of those affected by the changes recorded, but the great preponderance of the cases of a shortened working week is significant. The particulars furnished in later years by the Labour Department are much more precise, and show the following results for the years 1893–1900. By the cases of which full particulars have been received, again exclusive of agricultural labourers, railway servants, and seamen, 446,169 wage-earners were affected, and of these only 82,367 had their working day lengthened. Not only has a much larger number secured a decrease, but the gain of time per head has been much greater than the loss; for while 76,663, or nearly the whole of those whose average working week was increased, submitted to an increase of less than one hour per week, the average time in each year by which the working week was shortened for the trades reported on was 2·81 hours.

But while there is much detailed evidence of somewhat greater leisure and of considerably increased wages, and still more general evidence of a rising standard of comfort, other considerations point to less satisfactory conclusions. Female labour is, it is true, being gradually still further withdrawn from those occupations for which it is physically least fitted, and is widely protected by legislation, especially as regards the hours of work, in ways that would be inexpedient for adult males; but it still remains subject to many special disadvantages, both as regards conditions of employment and as regards wages. This inferiority is largely due to disorganization and to non-organization; to the disadvantages that the woman still labours under of being regarded as a supplementary wage-earner; and, frequently, to the aggravation of the normal sources of her economic weakness through the conditions of home employment. As regards the poorly-paid and unhappily-conditioned classes of female labour, as also of inefficient, disorganized, and degraded labour generally, both of men and women, Mr Charles Booth's conclusion has to be borne in mind, that some 30 per cent. of the people of London are to be classed as "poor," either through the lowness of the rate at which they are paid, through the irregularity of their employment, or through the general precariousness of their means of subsistence. Moreover, the figures for overcrowding for England and Wales have to be considered. According to the returns for 1891, in which "ordinary tenements which have more than two occupants per room, bedrooms and sitting-rooms included," are regarded as overcrowded, it appears that, in the urban districts, 2,572,413 persons were found to be living in one, two, three, or four rooms in such conditions, and in the rural districts, 685,631 persons—the two totals representing in the aggregate more than 11 per cent. out of a total population of something over 29 millions. Many people are doubtless housed beneath their earnings, the margin saved in rent and in keeping up the home standard being diverted into other channels and often wasted. But it may be broadly stated that accommodation is a rough index not only to the standard of comfort of the household, but also to the economic status of the householder. The two sets of figures given above may therefore be usefully put side by side with the indications of progress already given, in order to indicate the serious limitations of such improvement in material conditions as has taken place.

Influence of Combination.—The legal position of the Trade Unions (*q.v.*) was settled in 1876, and since that date, in spite of some uncertainty as to the nature of lawful and unlawful picketing, and, in this connexion, as to the financial liability of the societies in the case of actionable conduct on the part of a member, they have been comparatively free to concentrate attention upon internal management, and upon the task of making combination effective. From 1880 to 1888 a large number of new societies were started, but those in which any rapid augmentation of strength took place were exceptional—for instance, among the older societies, in the Boiler Makers and, to some extent, in the Amalgamated Society of Engineers. Trade unionism still represented skill, and for the most part afforded additional protection to those classes of workers whose own economic position was already strong. The trade union mind of these years, when the depression and financial strain of 1879 and the immediately succeeding years had been left behind, is reflected in the first Report on Trade Unions prepared in 1887 by the Labour Correspondent of the Board of Trade. Writing of the complete emancipation in the eyes of the law that the societies had obtained, he continued: "There can be no doubt that the freedom which in this respect they now enjoy tends to make them the most contented industrial community in the world." At this date the total membership throughout the United Kingdom was estimated at something over 600,000. In 1889 a great change took place. The apparently successful issue of what has come to be known as "the great dock strike" of that year in London appeared suddenly to open up a new era for trade unionism. The discovery seemed to be made, not, it is true, for the first time, that the unskilled could be organized no less than the skilled. New combinations were formed up and down the country. Even more important than this, the older societies were led to bestir themselves more actively. The figures relating to the annual Trade Union Congresses reflect the inflation and the enthusiasm of 1890. In 1889 there had been only 209 delegates present, representing 145 societies and less than 700,000 members, but in the following year there were 454 delegates, representing 268 societies and nearly 1,600,000 members. From 1891 until 1895 the total of the trade unionists in the United Kingdom appears somewhat to have declined, mainly owing to the falling-off in the membership of general labourers, agricultural labourers, and transport employés (other than railway men). This was the period of declining trade, and also of readjustment, following on the years of excitement that had preceded, but since 1895 a steady advance has been made. The trade unionists of the United Kingdom in 1900 were put down at 1,905,116, an increase of nearly half a million on the total given for 1895, and may be roughly estimated to include something under one in four of the class of men from whom members are drawn. The total number of unions at the end of 1900 was 1272, about 57 per cent. of which had been formed from 1880

onwards, and about 38 per cent. from 1890 onwards. A slight tendency towards consolidation is observable, but very many of the societies are still small, local, and unimportant, there being 815 of them with less than 300 members each, and with an average membership of only a little over 100. About three-fifths of the membership belong to the societies designated by the Labour Department as "the hundred principal trade unions," the position and importance of which will be best seen from the following particulars taken from the Report on Trade Unions, 1900:—Total income for the year, £1,974,611; total funds in hand, £3,766,625, equivalent to £3, 5s. 0d. per member; dispute pay, £150,283; unemployed benefit, £265,328; sick and accident benefit, £323,231; superannuation, £190,039; funeral benefit, £98,682. From 1892–1900 these 100 societies expended upwards of 13½ million pounds, in the following proportions:—Dispute benefit, 20·2 per cent.; working expenses, 19·5 per cent.; and for friendly benefits of various kinds, no less than 60·3 per cent.

The primary object of every trade union must be a protective one, but the figures and percentages quoted above, showing the large expenditure on friendly benefits, prove the importance of the incidental benevolent work of the societies. The experience of the last decade of the 19th century, in spite of the heavy financial burden imposed, afforded further proofs of the necessity of combining the benevolent with the more militant objects, in order that the bond of a permanent and obvious material gain to members may be provided. The usefulness of the trade unions in providing, on the side of the wage-earner, the general machinery for the maintenance of organized relationships between "capital and labour," a machinery that is as potent in the preservation of industrial peace as it is for entering upon industrial conflict; the statistical value of the returns of the societies, as throwing considerable light not only on the state of employment in particular trades, but to some extent on more general conditions; and the means which the societies provide for the expression of representative working-class opinion, when this exists, are among the various advantages both to the community at large and to the wage-earning classes in particular that the stability of these organizations ensures. It must be observed, however, that the Trade Union Congress, the most representative organization of the trade unions, has declined in importance. This has been largely due to the division that has made itself felt on questions of political action and principle, and to the more or less veiled conflict that has arisen between the Socialistic and the non-Socialistic elements at the Congress; while another source of weakness, to some extent arrested by recent improvements in procedure, has been the multitude of questions that are brought before the meetings. The increasing strength and scope of the employers' associations that has taken place, *pari passu* with the growth and consolidation of the trade unions, has been a marked and significant feature of recent years.

One of the most definite ways in which trade union influence has shown itself in recent years has been in the conditions under which labour has been employed by public authorities, and in the extent to which a "fair wages clause," in some form or another, has been inserted in public contracts. Exclusive of London, where the County Council and many of the boroughs have adopted stringent clauses, it is noteworthy that in the Government Return (1898) of Urban Sanitary Districts showing whether contracts entered into "specify any conditions as to the wages to be paid by the contractor, or other conditions with respect to the persons employed by him," no fewer than forty-eight of the county boroughs are found to have adopted some such conditions, as against sixteen in which no conditions are directly enforced. The conditions specified vary considerably in stringency; and while some deal simply with the question of competency, and a few even insist on the employment of local labour, the great majority enforce the payment of not less than "the current local standard rates of wages," and the observance of the hours and other conditions of employment recognized. Inasmuch as these clauses involve the public recognition of a standard and a groping after fairness, their extended adoption perhaps represents one of the most far-reaching effects of trade unionism. In general, however, it may be said that the societies are much more successful in securing the adoption of shorter hours, or of other conditions affecting the convenience, healthiness, and safety of labour, than in enforcing higher wages. They can more easily introduce a uniform wage than increase the aggregate of earnings, the amount, and even the rate, of the latter being determined by more general influences than the presence or absence of combination. In one special direction, namely, among workmen employed by local bodies, especially all forms of unskilled labour (street-sweeping, &c.), the increase in wages has coincided with a rise in the standard of the requirements for what used to be regarded as the inferior services demanded by the community, employers, be they municipal or private, tending inevitably to secure the most efficient labour that is willing to take the wage offered. Thus the man who is handicapped in any way, be it by the infirmity of age or by any other physical cause, is finding it increasingly difficult to secure employment in directions to which, in years gone by, he had naturally turned. Analogous effects are discernible in many fields of employment in which the trade unions have been able to enforce the payment of not less than a fixed minimum wage. This is indeed one of the difficulties that the community at large is having to face at this era of partial organization, coinciding as it necessarily does with the existence of a large amount of labour that is, through lack of training, through deterioration, through infirmity, or from some other cause, below the average and inefficient, and thus, though not unemployable, often unemployed. (E. A*.)

Society Islands. See Tahiti.

Sociology.—In the most inclusive sense sociology may be defined as the science of human society, in the same manner that biology may be taken to imply the science of life. The fact that sociology is treated in these new volumes of the *Encyclopaedia Britannica* for the first time under a separate heading is indicative of a certain tendency in the development of the subject, the bearing of which will be referred to later. The word sociology (*Sociologie*) was first used by Comte in 1839 as an equivalent of the expression social physics previously in use, and was introduced, he said, to describe by a single term that part of natural philosophy which relates to the positive study of the fundamental laws of social phenomena. Although the word is a hybrid, compounded from both Latin and Greek terms, its use has been defended, and is now generally accepted; none of the terms, such as politics, social economy, social philosophy, and social science, which have been suggested instead of it having succeeded in taking its place. There has been in the past a certain hesitation, especially in England, to admit sociology as the title of a particular science in itself until it was made clear what the subject must be considered to cover. In certain quarters sociology is often spoken of as if it implied the practical equivalent of the science of politics. Henry Sidgwick considered the word as usually

employed in this sense, and while he recognized that sociology must have a wider scope than politics, he thought that in practice "the difference between the two subjects is not indeed great" (*Elements of Politics*). In other quarters the word is often used as no more than a covering term for subjects which are fully treated in various subdivisions of social science. In others, again, a certain distinction is made, and sociology is used as an ordinal term to include the general principles of a subject of which the details are treated in subdivisions. Thus when the science of society is distinguished from the special social sciences which fall within its general purview, it may be considered, says Lester F. Ward, that "we may range the next most general departments as so many genera, each with its appropriate species. That is, the classification of the sciences may be made strictly synoptical. When this is done it will be possible for philosophers, like good systematists, to avoid making their ordinal characters include any properly generic ones, or their generic characters include any that are only specific. Thus understood, sociology is freed from the unnecessary embarrassment of having hanging about it in more or less disorder a burden of complicated details, in a great variety of attitudes which make it next to impossible to secure due attention to the fundamental principles of so vast a science. These details are classified and assigned each to its proper place (genus or species), and the field is cleared for the calm contemplation of the central problem of determining the facts, the law, and the principles of human association" (*Outlines of Sociology*). This definition, good as it is in many respects, does not, however, in practice make clear to the mind whether the principles of sociology involve more than the generalized total of the principles of the subordinate sciences which it is said to include. Finally, in England Herbert Spencer, who has been one of the principal writers identified with the subject in a period of transition, has placed his *Principles of Sociology* between his *Principles of Psychology* and *Principles of Ethics*. In practice, however, ethics, as Sir Frederick Pollock has pointed out, must be classed as a department of sociology. For "whatever may be thought of the existence of absolute or purely self-regarding duties, or of the possibility of a moral sense, arising otherwise than in society, it is understood that the great bulk of moral duties have regard to other persons" (*History of Science of Politics*). Psychology, on the other hand, which Mr Spencer places before sociology, cannot nowadays be fully, or even in any real sense scientifically, discussed apart from sociological principles, once it is accepted that the evolution of society is proceeding under the influence of natural selection, and that therefore the social factor is always in the ascendant—in the development of the human mind no less than in the development of human conduct.

It would appear, therefore, that if sociology is to be admitted as a true science in itself, it must be regarded rather as a science occupied more particularly with the general fundamental principles which underlie human society considered as in a condition of change. In this sense, if its claim be established, it must be possible to show that while the conclusions of sociology cannot be fully stated in relation to the phenomena dealt with in any of the divisions of social science, they must be taken as implying more than the sum total of the results obtained in all of them, and therefore as involving governing principles to which the phenomena of all of them stand in controlled and subordinate relationship.

The fathers of the science of society may be said to be the Greek philosophers, and in particular Plato and Aristotle. The *Laws* and the *Republic* of the former and the *Ethics* and *Politics* of the latter have, down to modern times, and notwithstanding the great difference in the standpoint of the world and the change in social and political conditions, exercised a considerable influence on the development of the theory of society.

Among the Greeks.

To the Greeks the science of society presented itself briefly as the science of the best method of attaining the most perfect life within the consciousness of the associated life of the State. "In this ideal of the State," says Bluntschli, "are combined and mingled all the efforts of the Greeks in religion and in law, in morals and social life, in art and science, in the acquisition and management of wealth, in trade and industry. The individual requires the State to give him a legal existence: apart from the State he has neither safety nor freedom. The barbarian is a natural enemy, and conquered enemies become slaves. . . . The Hellenic State, like the ancient State in general . . . was all in all. The citizen was nothing except as a member of the State. His whole existence depended on and was subject to the State . . . The State knew neither moral nor legal limits to its power" (*Theory of the State*).

It was within the limits of this conception that most of the Greek theories of society were constructed. The fundamental conception of the Roman writers was not essentially different, although the opportunism of the Roman State, when it became a universal power embracing the social and religious systems of many peoples, in some degree modified it; so that with the growth of *jus gentium* outside the *jus civile*, the later writers of the Empire brought into view an aspect of the State in which law began to be to some extent distinguished from morality.

In Christian Europe.

With the rise and spread of Christianity in Western Europe there commenced a stage in which the social structure, and with it the theory of society, underwent profound modifications. These changes are still in progress, and the period over which they extend has produced a great and increasing number of writers on the science of society. The conceptions of each period have been intimately related to the character of the influences controlling development at the time. The writers up to the 14th century are nearly all absorbed in the great controversy between the spiritual and temporal power which was defining itself during this stage in Western history. In the period of the Renaissance and the Reformation the modern development of the theory of society may be said to begin. Machiavelli is the first great name in this period. Bodin with other writers up to the time of Montesquieu carry the development forward in France. The Dutch writer Grotius, although chiefly recognized at the time as an authority on international law, had much influence in bringing into view principles which mark more directly the transition to the modern period, his *De Jure Belli et Pacis*, issued in 1625, being in many respects an important contribution to the theory of society. Hobbes and Locke are the principal representatives of the influential school of writers on the principles of society which the period of the political and religious upheaval of the 17th century produced in England. The ideas of Locke, in particular, exercised a considerable influence on the subsequent development of the theory of the State in Western thought. From the 17th century forward it may be said, strictly speaking, that all the leading contributions to the general body of Western philosophy have been contributions to the development of the science of society. At the time of Locke, and to a large extent in Locke's writings, there may be distinguished three distinct tendencies in the prevailing theory of society. Each of these has since become more definite, and has progressed along a particular line of

development. There is first the empirical tendency, which is to be followed through the philosophy of Hume down to the present day, in what may be called—to borrow an idea from Huxley—the physiological method in the modern study of the science of society. A second tendency—which developed through the critical philosophy of Kant, the idealism of Hegel, and the historical methods of Savigny in the field of jurisprudence and of the school of Schmoller in the domain of economics—finds its current expression in the more characteristically German conception of the organic nature of the modern State. A third tendency—which is to be followed through the writings of Rousseau, Diderot, d'Alembert, and the literature of the French Revolution—found its most influential form of expression in the 19th century in the theories of the English Utilitarians, from Bentham to John Stuart Mill. In this development it is a theory of the utilitarian State which is principally in view. In its latest phase it has progressed to the expression which it has reached in the theories of Marxian Socialism, in which the corresponding conception of the ascendancy of the economic factor in history may now be said to be the characteristic feature. All of these developments must be considered to have contributed towards the foundation of modern sociology. The definition of the relations to each other of the positions which they have severally brought into view is not unlikely to be the first important work of the new science.

Comte. At the period between 1830 and 1842, when Comte published the *Philosophie Positive*, the conditions were not ready for a science of society to be instituted. The Darwinian doctrine of evolution by natural selection had not yet been enunciated, and knowledge of social phenomena was limited and very imperfect. As an instance of the character of the change that has since been in progress, it may be mentioned that one of Comte's main positions—that, indeed, to which most of the characteristic conceptions of his system of philosophy were related—was that "the anatomical and physiological study of individual man" should precede the theory of the human mind and of human society. It is probable, however, that it must now be considered that no really fundamental or far-reaching principle of human development can be formulated as the result of such a position. For with the application of the doctrine of evolution to society a position is becoming defined which is almost the reverse of it, namely, that the development of the individual, and to a large extent of the human mind itself, must be regarded as the correlative of the social process in evolution. The study of the principles of the process of social evolution would therefore in this sense tend to come before the complete study of the individual, and even to precede the construction of a system of pyschology scientific in the highest sense. Comte, apart from his want of mastery of the historical method in dealing with sociological development, possessed, on the whole, little insight into the meaning of the characteristic problem in which the human mind is involved in its social evolution, and to the definition of which not only the processes of Western history, but the positions successively developed in Western thought, must all be considered as contributing. His great merit was the perception of the importance of the biological method in the science of society, the comprehension of the fact that there can be no science of society if its divisions are studied apart from each other; and finally, and although it led at the time to the formulation of no important principle of human development, the intuition that sociology was not simply a theory of the state, but the science of what he called the associated life of humanity.

It has to be observed, that preceding the application of the doctrine of evolution to society most of the contributions to social science have a certain aspect in which they resemble each other. While in later theories society tends to be presented as evolving inevitably, under stress of natural selection, towards efficiency, the earlier contributions tend to become theories of the meaning and object of society regarded simply as a medium for the conscious realization of human desires along the line of least effort in the associated state.

Influence of Greek conceptions of the State. In this presentation of the subject the influence of the Greek conception of the State upon modern sociology may be traced down to the present day. At the beginning of the modern period it reappears in Machiavelli (*Titus Livius*, i., iii., and *The Prince*). It is represented in modified form in Hobbes (*Leviathan*), and in Locke (*Two Treatises of Government*), each of whom conceived man as desiring to leave the state of nature and as founding civilized society, "in order that he might obtain the benefits of government" in the associated state. It is continued in Rousseau and the writers of the French Revolution, who similarly imagined the individual voluntarily leaving an earlier state of freedom to put "his person and his power under the direction of the general will" (*Social Contract*). It is characteristic of Jeremy Bentham (*e.g., Principles of Morals and Legislation*, i.) and of J. S. Mill (*e.g., Utilitarianism and Political Economy*, iv., vi.). Finally, it survives in Herbert Spencer, who in like manner sees man originating society and submitting to political subordination in the associated state "through experience of the increased satisfaction derived under it" (*Data of Ethics*). It continues at the present day to be characteristic of many Continental and some American writers on sociology, who have been influenced both by Spencer and the Latin theory of the State, and who therefore, conceiving sociology not so much as a science of social evolution as a theory of association, proceed to consider the progress of human association as the development of a process "of catering to human desire for satisfactions of varying degrees of complexity" (Small). With the application of the theory of natural selection to human development this conception may be observed as tending to be replaced by that already mentioned, which is different both in character and implication.

Result of doctrine of evolution. In the later view, while the positions involved in the first conception of society are not lost sight of, the development of human society is regarded rather as the product of a process of stress, in which progress results from natural selection along the line, not of least effort in realizing human desire, but of the highest social efficiency in the struggle for existence of the materials of which society is composed. In the intensity of this process society, evolving towards higher efficiency, tends to become increasingly organic, the distinctive feature being the growing subordination of the individual to the social process. All the tendencies of development—political, ethical, and psychological—and the contents of the human mind itself, would therefore have to be regarded as having ultimate relations to the governing principles of the process as a whole. The science of social evolution would, in short, have to be considered, according to this view, as the science of the causes and principles subordinating the individual to a process developing by inherent necessity towards social efficiency, and therefore as ultimately over-ruling all desires and interests in the individual towards the highest social potentiality of the materials of which society is composed. The conflict between these two conceptions may be distinguished to an increasing degree as the scope of modern sociology has gradually become defined; and the opposing principles and ideas of each may be observed to be sometimes represented and blended, in varying degrees of complexity, in one and the same writer.

It was natural that one of the first ideas to be held by theorists, as soon as sociology began to make progress to the position of a real science, was that society must be considered to be organic. An increasing number of writers from Comte onwards have been concerned with this aspect of the subject, and in connexion with it there is brought into view the nature of the situation towards which the conflict referred to has gradually developed. Comte conceived social organization as more or less mechanical. Writers like Herbert Spencer (*Sociology*) and Schäffle, who was for a time Minister of Commerce for Austria (*Bau und Leben des Socialen Körpers*) have instituted lengthy comparisons between the social organism considered as the State and the living individual organism. These efforts may be said to have reached their most characteristic current expression in the work of the sociologists who have followed Simmel in lengthy and ingenious attempts at classifying associations, considering them "as organizations for catering to human desire." In all these attempts the Greek theory of society may be said to be still vigorously represented, although, as has been said, the old is often blended with the new in one and the same writer. In their later phases they may be recognized to be, to a considerable extent, characteristic of the work of sociologists in countries where the influence of Roman law is still strong, and where, consequently, the Latin conception of the State associated with it tends to influence all theories of society as soon as the attempt is made to place them on a scientific basis. The sterilizing effect which the example has produced on the study of sociology in certain directions in America has, however, to be noted. It is exemplified in ingenious attempts which are made, in dealing with the principles of sociology, to construct long categories of human associations, ranging from those based on mental abnormality to those that result in joint participation in choral music. There is to be distinguished an increasing conviction that none of the comparisons of this kind that have hitherto been made have contributed in any marked degree to the elucidation of the principles of modern society. Paul Leroy Beaulieu's criticism of Schäffle's effort at comparisons—anatomical, physiological, biological, and psychological—between society and the human individual is that "the mind sinks overwhelmed under the weight of all these analogies, these endless divisions and subdivisions to which they give rise. . . . The result is not in proportion to the effort" (*L'État moderne et ses fonctions*).

Society as an organism.

In tracing the direction of this conflict between the newer and older tendencies in modern sociology, it is probably in Herbert Spencer's writings that the student will find presented in clearest definition the characteristic difficulty with which the old view has tended to be confronted, as the attempt has continued to be made to enunciate the principles of human development from the standpoint that society is to be considered as a "social organism." With the application of the doctrine of natural selection to society considered as an organism, a position has been brought into view of considerable interest. It is evident that a fundamental principle involved in considering society as an organism, is that the efficiency of the social organism must always be taken to be greater than the sum total of the efficiencies of all the members that comprise it, acting as individuals. The inference which follows from this, is that if natural selection is to be considered as operating in society along the line of highest efficiency, it must reach the individual through society. That is to say, his development and his interests as an individual must be regarded as having ceased to be the controlling factor in social evolution. It is the principles subordinating him to the efficiency of society in its corporate aspect which must ultimately control both, and, therefore, all theories whatever of human association. Mr Spencer, in an elaborate comparison which he has made (*Essays*, vol. i., and *Principles of Sociology*) between the social organism and the living individual organism, has insisted on a reservation which brings into view, in connexion with this fact, a position the relation of which to present tendencies in sociology is probably fundamental. In comparing the social with the individual organism he proceeds, after noting the various aspects in which a close analogy between the two can be established, to make, as regards modern society, an important distinction by which the nature of the difficulty in which he is involved is immediately made apparent. While in an individual organism, he points out, it is necessary that the lives of all the parts should be merged in the life of the whole, because the whole has a corporate consciousness capable of happiness or misery, it is not so with society. For in society, he adds, the "living units do not and cannot lose individual consciousness, since the community as a whole has no corporate consciousness." Mr Spencer proceeds, therefore, to emphasize the conclusion that "This is an everlasting reason why the welfare of citizens cannot rightly be sacrificed to some supposed benefit of the State; but why, on the other hand, the State is to be maintained solely for the benefit of citizens. The corporate life must here be subservient to the lives of the parts, instead of the lives of the parts being subservient to the corporate life." The position to which this conception of Mr Spencer—in which the State is conceived to be the "social organism"—gave rise, as the doctrine of evolution continued to be applied to society, was defined in the prefatory essay to vol. xxix. of the present edition of the *Encyclopædia Britannica*. Briefly stated, the characteristic difficulty which presented itself was that: If natural selection is conceived as operating on society, and therefore as tending to produce the highest efficiency out of the materials that comprise it, it must produce the subordination of the interests of the units to that higher efficiency of society, which is greater than the sum total of the efficiencies of the component members. But one of only two conclusions could therefore result from Mr Spencer's position. In regarding the "social organism" as an organism in which the corporate life must be subservient to the lives of the parts, instead of the lives of the parts being subservient to the corporate life, it must be necessary to conceive that the individual had succeeded in arresting the characteristic effects of natural selection on society. Or else, the result just mentioned being scarcely conceivable, natural selection, whether the individual be conscious of it or not, must be subordinating individual interests in society to a larger meaning in the evolutionary process. Society must, in short, be subject to principles which reach farther than Mr Spencer conceived: it must be organic in some different and wider sense than he imagined, and the analogy of the "social organism" as confined within the consciousness of ascendant interests in the political State must be considered to be a false one.

Herbert Spencer.

In the essay in question the gradual *reductio ad absurdum* which has taken place, with the application of the doctrine of evolution to society, of the conception that natural selection tends to be suspended in the social process, was dealt with and may be there followed in detail. It remains here to consider the relation to the position in modern sociology of the other alternative, namely, that society must be considered to be organic in some wider sense than the principles of the State would imply. The position reached in Mr Spencer's sociology may be said to

Further extension to sociology of the evolutionary principle.

represent the science of society in a state of transition. It represents it, that is to say, in a stage at which the Greek theory of society has become influenced by the doctrine of evolution applied to modern conceptions, but while as yet no synthesis has been achieved between the conflicting and even mutually exclusive ideas which are apparently involved. The Greek theory of society is represented in Mr Spencer in his practical identification of "the social organism" with the State. The idea, however, which carries him beyond the principles of Greek society—as these principles were summarized, for instance, in the passage already quoted from Bluntschli—is clearly in evidence. It may be observed to be expressed in the recognition of a principle resident in modern society which in some manner projects the individual's rights outside and beyond the whole theory and meaning of the State. In other words, in society as Mr Spencer now conceives it, "the welfare of citizens cannot rightly be sacrificed to some supposed benefit of the State"; whereas, according to the Greek theory and the theory of Roman law, "the citizen was nothing, except as a member of the State. His whole existence depended on and was subject to the State. The State knew neither moral nor legal limits to its power." If, however, it be considered that modern society has made progress beyond the Greek, and if it be accepted that the theory of evolution involves the conclusion that society progresses towards increased efficiency in a more organic type, there follows from the foregoing an important inference. This is that it would then become the task of modern sociology, as a true science, to show that the principle in modern civilization which distinguishes it from society of the Greek period—namely, that principle which Mr Spencer rightly recognizes as rendering the life of the individuals as no longer subservient to the corporate life of the State—is itself a principle identified with the increasing subordination of the individual to a more organic type of society. It must, in short, remain for the evolutionist, working by the historical method scientifically applied, to present the intervening process in history—including the whole modern movement towards liberty and enfranchisement, towards equality of conditions, of rights, and of economic opportunities—as a process of progress towards a more advanced and organic stage of social subordination than has prevailed in the world before.

It is at this point that the wide scope of modern sociology comes into view, and that the advanced character of the studies which must form its basis may be realized. It is not, it would appear, only the facts of primitive society, the general theory of the political State, and the principles of economic society, that come within its purview. The developments of history and the positions successively defined in human thought and in human belief must, it would seem, all fall to be considered in a strictly scientific sense as constituting the phenomenology of a process in which, with the evolution of society towards higher efficiency, the individual is being gradually subordinated to principles rendering society increasingly organic.

Hitherto, in the development of sociological theory, the tendency which has led to the identification of the social organism with the State has been productive of certain more or less characteristic results. In the first place, by the considerable number of writers who have, as stated, tended to consider sociology as the study of associations for realizing human desires, beginning with those of primitive society and rising to the economic wants of the modern State, attention has necessarily been given to institutions of custom and legality, to civil and economic phenomena, and, in the study of modern society, to statistical methods and quantitive measurements in connexion with facts relating to such subjects as wealth, industry, health, crime, education, and forms of economic activity. In sociology thus considered, the legal and economic aspects of society, and the theory of the State as constituting the social organism, have tended to be kept in view. An incidental but by no means unimportant result has, however, been that, as Mr Lester Ward has pointed out, sociologists have been hitherto recruited mainly from students of economics or of subdivisions of economic science. While such studies must always continue to constitute an important part of the science of society, it must be considered that the tendency in the past to give them so prominent a place, as constituting the subject-matter of the science, has hitherto unduly restricted the outlook in sociological study. The conception of sociology as occupied with the general fundamental principles which underlie society considered in a condition of change, and therefore as involving governing principles to which the phenomena of all departments of social science stand in controlled and subordinate relationship, renders it necessary that the science should cover the subjects of a wide field of advanced study. When society is considered as an organism developing under the influence of natural selection along the line of the causes which contribute to its highest potential efficiency, and therefore tending to have the mean centre of its organic processes projected farther and farther into the future, it is evident that it must be the principles and ideas which most effectively subordinate over long periods of time the interests and the capacities of the individuals of which it is composed to the efficiency of the whole which will play the leading part in social evolution. The position of sociology, therefore, follows, as the most advanced of all the theoretical sciences. With the application of the doctrine of evolution to the social process in history, it must necessarily be concerned with all the subjects included under the old philosophy of history; while, on the other hand, when the contents of the individual mind are viewed as the correlative of the evolutionary process in society, the ultimate problems of ethics and psychology are also seen to be involved. The foundations of the science of society cannot, in short, be firmly or permanently laid with the comparatively limited outfit with which the sociologist has often been content to work in the past.

The basis of modern sociology.

A consideration of the general outlines of the process in which society must be considered as developing towards a higher organic efficiency under the operation of natural selection brings into view the scope of the studies which are thus likely to form the basis of sociology as a science in the modern sense, while it gives at the same time some general impression of the character of the results by which it is possible that a synthesis of the later with the older views may in time be attained. Beginning with primitive society, it must be considered that the first rudiments of social organization arose, not so much from conscious regard to expediency or "increased satisfactions," as from fitness in the struggle for existence. "The first organized societies must have been developed, like any other advantage, under the sternest conditions of natural selection. In the flux and change of life the members of those groups of men which in favourable conditions first showed any tendency to social organization became possessed of a great advantage over their fellows, and those societies grew up simply because they possessed elements of strength which led to the disappearance before them of other groups of men with which they came into competition. Such societies continued to flourish, until they in their turn had to give way before other associations of men of higher social efficiency" (*Social Evolution*, ii.). In the social process at this stage all the customs, habits, institutions, and beliefs

contributing to produce a higher organic efficiency of society would be naturally selected, developed, and perpetuated. It is in connexion with this fact that the clue must be sought to the evolution of those institutions and beliefs of early society which have been treated of at length in researches like those of M'Lennan, Tylor, Lubbock, Waitz, Letourneau, Quatrefages, Frazer, and others of equal importance. For a long period in the first stages the highest potentiality of the social organization would be closely associated with military efficiency. For in the evolution of the social organism, as has been said, while the mean centre of the processes involving its organic identity would tend to be projected into the future, it would at the same time always be necessary to maintain efficiency in current environment in competition with rival types of lower future potentiality. Amongst primitive peoples, where a great chief, law-giver, and military leader appeared, the efficiency of organized society resting on military efficiency would, as a matter of course, make itself felt in the struggle for existence. Yet as such societies would often be resolved into their component elements on the death of the leader, the overruling importance—in the next stage of the advance towards a more organic type—of ideas which would permanently subordinate the materials of society to the efficiency of the whole would make itself felt. Social systems of the type in which authority was perpetuated by ancestor-worship—in which all the members were therefore held to be joined in an exclusive religious citizenship founded on blood relationship to the deities who were worshipped, and in which all outsiders were accordingly treated as natural enemies, whom it would be a kind of sacrilege to admit to the rights of the State—would contain the elements of the highest military potentiality. The universal mark which ancestor-worship has left on human institutions in a certain stage of social development is doubtless closely associated with this fact. The new and the older tendencies in sociology are here also in contrast; for whereas Herbert Spencer has been content to explain ancestor-worship as arising from an introspective and comparatively trivial process of thought assumed to have taken place in the mind of early man in relation to a supposed belief in ghosts (*Principles of Sociology*, 68–207), the newer tendency is to consider science as concerned with it in its relation to the characteristic principles through which the efficiency of the social organization expressed itself in its surroundings. The social, political, and religious institutions disclosed in the study of the earliest civilizations within the purview of history must be considered to be all intimately related to the ruling principles of this military stage. The wide reach and significance of the causes governing the process of social evolution throughout the whole of this period may be gathered from treatises like Seebohm's *Structure of Greek Tribal Society*, Maine's *Ancient Law*, *History of Institutions*, and *Early Law and Custom*, Fowler's *City-State of the Greeks and Romans*, and in a special sense from the comparative study of Roman law, first of all as it is presented in the period of the Twelve Tables, then as the *jus civile* begins to be influenced by the *jus gentium*, and lastly as its principles are contrasted with those of English common law in the modern period. In most of the philosophical writings of the Greeks, and in particular in the *Ethics* and *Politics* of Aristotle, and in many of the *Dialogues* of Plato, the spirit of the principles upon which society was constructed in this stage may be perceived as soon as progress has been made with comparative studies in other directions.

Where, however, all human institutions, as in this stage, rested ultimately on force; where outsiders were regarded as natural enemies, and conquered enemies became slaves; where, as throughout all this phase of social evolution, a rule of religion was a rule of law identified with the principles of the State (Maine, *Ancient Law*); where the State itself was absolute as against the individual, knowing "neither moral nor legal limits to its power"; and where all the moral, intellectual, and industrial life of the community rested on a basis of slavery—the full limits of the organic principle in society would in time be reached. The conditions would be inherent in which all social institutions would tend to become closed absolutisms organized round the conception of men's desires in the present. And the highest outward expression in which the tendencies in ethics, in politics, and in religion must necessarily culminate would be the military State, bounded in its energies only by the resistance of others, necessarily acknowledging no complete end short of absolute dominion, and therefore staying its course before no ideal short of universal conquest.

As society continued to be impelled to develop towards a still more organic type, the greatly higher potentiality of a state of social order which, while preserving the ideal of the highly organized State and the current efficiency of society in competition with lower types, would be influenced by conceptions that would dissolve all those closed absolutisms, and release human energies into a free conflict of forces by projecting the principles of human responsibility outside the State, would be apparent. The conditions in which such a stage has in some degree tended to be attained in Western history were exemplified in the Prefatory Essay to vol. xxix. In many of the religions of the East such conceptions are to be found in all stages of development. But no Eastern people has, down to the present time, been able to provide for them the permanent military *milieu* in history in which alone their potentiality in the evolutionary process could be realized. The significance, therefore, of the culmination of the military epoch in the ancient classic civilizations of the Western world which preceded the opening of the era in which we are living, and of the fact that the peoples of the same descent who were destined to carry on the civilization of the existing era represent the supreme military stock by natural selection, not only of the entire world, but of the evolutionary process itself in human history, will be evident. With the spread, accordingly, amongst peoples of this origin, and in such a *milieu* in history, of a new conviction of responsibility to principles extending beyond the consciousness of the political State, there would begin a further and more organic stage of the evolutionary process in society. The gradual dissolution in the era in which we are living of all the closed absolutisms within the State, in which human action and ideas had hitherto been confined, is apparently the characteristic phenomenon of this stage. Progress is towards such a free and tolerant, but intense and efficient, conflict of forces as was not possible in the world before. It is, it would appear, in this light that we must regard the slow dissolution of the basis of ideas upon which slavery rested; the disintegration of the conceptions which supported the absolute position of the occupying classes in the State; the undermining of the ideas by which opinion was supported by the civil power of the State in the religious struggles of the Middle Ages; the growth of the conception that no power or opinion in the State can be considered as the representative of absolute truth; the consequent development of party government amongst the advanced peoples, with the acknowledgment of the right of every department of inquiry to carry results up to that utmost limit at which they are controlled only by the results obtained in other departments of activity with equal freedom; the growth of the conception, otherwise

absurd, of the native equality of men; the resulting claim, otherwise similarly indefensible, of men to equal voting power irrespective of status or possessions in the State, which has been behind the movement towards political enfranchisement; and, finally, the development of that conviction which is behind the existing challenge to all absolute tendencies in economic conditions in the modern world—namely, that the distribution of wealth in a well-ordered State should aim at realizing political justice. These are all the features of an integrating process in modern history. They must be considered as all related to a controlling principle which has rendered the evolutionary process in society more organic than in any past stage: namely, the projection of the sense of human responsibility outside the limits of all the creeds and interests which had in previous stages embodied it in the State (*Principles of Western Civilization*, x., xi.).

In thus regarding the social process in Western history, the projected efficiency of which, now after many centuries of development, begins to realize itself to an increasing degree in determining competition with other types of society throughout the world, it may be observed that the results by which a synthesis of the older and later views may be attained is already in some measure in sight. It was pointed out that if the principle which Mr Spencer rightly recognized in modern society as rendering the life of the individual no longer subservient to the corporate life of the State was to be accepted as a principle of progress distinguishing modern civilization from that of the Greek period, it would be necessary for the scientific sociologist to exhibit it not as indicating the larger independence of the individual, but as a principle identified with the increasing subordination of the individual to a more organic type of society. Here, therefore, this result is apparently in process of accomplishment. The intervening process in history—including the whole modern movement towards liberty and enfranchisement, towards equality of conditions, of rights, and of economic opportunities—is presented "as a process of progress towards a more advanced and organic stage of social subordination than has prevailed in the world before (*Principles of Western Civilization*, xi.). In this light, also, it may be observed how the claim of sociology to be the most advanced of all the theoretical sciences is justified. For if the historical process in the civilization of the era in which we are living is thus to be regarded as a process implying the increasing subordination of the individual to a more organic type of society, then the study of sociology as embracing the principles of the process must evidently involve the perception and comparison of the meaning of the fundamental positions disclosed in the history of political progress, of the problems with which the human mind has successively struggled in the phases of religious development, and, lastly, of the positions with which the intellect has been confronted as the stages of the subordinating process have gradually come to define themselves in history. The positions outlined in the developments already referred to which have come down through Hume and Huxley, through Kant and Hegel, through Grotius and Savigny, through Roscher and Schmoller, through the expression which English utilitarianism has reached in Herbert Spencer as influenced by the English theory of the rights of the individual on the one hand, and in Marxian Socialism as influenced by the Latin conception of the omnipotence of the State on the other, have thus all their place, meaning, and scientific relations in the modern study of sociology. It must be considered that the theory of organic evolution by natural selection and the historical method will continue in an increasing degree to influence the science of society. In the future, in the study of man, to make use of words employed by Sidgwick shortly before his death: "Owing to the overwhelming importance of the social factor [in the formation of a normal human individual], the methods of psychology and sociology blend in the inquiry, and the method of sociology dominates" (*Philosophy, its Scope and Relations*).

AUTHORITIES.—It has been one of the results of the conditions affecting sociology in the past, that many of the principal contributions to the science of society are not always included in lists of sociological references. The following are mentioned only as indicating or suggesting others in the same classes of equal or perhaps greater importance. The dates given are usually those of the first edition of a work:—

INTRODUCTORY.—DARWIN. *Origin of Species*, 1859; *Descent of Man*, 1871 (chapters dealing with society).—WALLACE. *Darwinism*, 1889.—ROMANES. *Darwin and after Darwin*, 1892.—OSBORN. *From the Greeks to Darwin*, 1894.—**Economics—Historical:** ASHLEY. *Introduction to English Economic History and Theory*, Part i. 1888, Part ii. 1893.—SCHMOLLER. *The Mercantile System*, 1884.—ROSCHER. *Geschichte der National-ökonomik in Deutschland*, 1874.—NYS. *History of Economics* (trans. DRYHURST, 1899).—**Ethics—Historical:** SIDGWICK. *History of Ethics*, 1886.—MACKENZIE. *Manual of Ethics*, 1893. **Primitive Society:** LUBBOCK. *Origin of Civilization*, 1870.—TYLOR. *Anthropology*, 1881.—QUATREFAGES. *Human Species*, Eng. trans. 1879.—LANG. *Custom and Myth*, 1884.—MAINE. *Ancient Law*, 1861; *Early History of Institutions*, 1875; *Early Law and Custom*, 1883.—FRAZER. *Golden Bough*, 1890.

GENERAL.—SPENCER. Synthetic Philosophy (*Principles of Biology, Principles of Sociology*, and *Principles of Ethics*).—KIDD. *Social Evolution*, 1894; *Principles of Western Civilization*, 1902.—BARTH. *Die Philosophie der Geschichte als Sociologie*, 1897.—WARD. *Dynamic Sociology; Outlines of Sociology*, 1898.—FLINT. *Philosophy of History in Europe*, 1874; *Historical Philosophy in France*, 1894.—BAGEHOT. *Physics and Politics*.—RATZENHOFER. *Die Soziologische Erkenntnis*, 1898.—GIDDINGS. *Principles of Sociology*, 1896.—TARDE. *Étude de Psychologie Sociale*, 1898.—STUCKENBERG. *Introduction to the Study of Sociology*, 1898.—STEPHEN. *The English Utilitarians*, 1900.—J. S. MILL. *System of Logic*, 1843; *On Liberty*, 1859; *Utilitarianism*, 1861.—COMTE. *Philosophie Positive*, 6 vols., 1830–42 (Eng. trans., condensed by Martineau, in 2 vols., approved by Comte, and retrans. into French).—BALDWIN. *Social Psychology*.—RITCHIE. *Natural Rights*, 1895. WESTLAKE. *International Law*, 1894.—BENTHAM. *Principles of Morals and Legislation*, 1780 (Oxf. ed., 1879).—SOHM. *Institutes of Roman Law*.—SANDARS. *Institutes of Justinian*.—LE ROY BEAULIEU. *L'État moderne et ses fonctions*.—HUXLEY. *Evolution and Ethics*, 1894.—NIETZSCHE. *The Twilight of the Idols; Zarathustra*.—LORIA. *Les bases économiques de la constitution sociale* (French trans.).—PEARSON. *National Life and Character*, 1893.—VINCENT. *The Social Mind in Education*, 1897.—MARX. *Kapital*, 1867 (Eng. trans. 1887).—ENGELS. *Socialism, Utopian and Scientific* (Eng. trans., Aveling, 1892).—GEORGE. *Progress and Poverty*.—MAZEL. *La Synergie Sociale*, 1896.—MALLOCH. *Aristocracy and Evolution*, 1898.—ROSS. *Social Control*, 1901.—MACKENZIE. *Social Philosophy*, 1895.—HOBSON. *The Social Problem*, 1901; *Fabian Essays*.—ROUSSEAU. *Social Contract*.—HOBBES. *Leviathan*.—LOCKE. *Two Treatises of Government*.—The WEBBS. *Industrial Democracy*, 1897; *History of Trades Unionism*, 1894.—BOOTH. *Life and Labour of the People*, 1891–97.—SPAHR. *Distribution of Wealth in the United States*, 1896.—GLADDEN. *Social Facts and Forces*, 1897.—LLOYD. *Wealth against Commonwealth*, 1894.—PATTEN. *The Theory of Prosperity*, 1902.—Vols. of *The Social Science Series* (Swan Sonnenschein).—ELLWOOD. "Prolegomena to Social Psychology"; SMALL. "The Scope of Sociology," *American Journal of Sociology*, 1899–1901.

References to the authorities for the historical periods, the events of which form the background of sociological study, need not be indicated here. (B. K*.)

Söderhamn, a seaport town of Sweden, county of Gefleborg, on a bay of the Gulf of Bothnia, 71 miles north

of Gefle by rail. It has saw-mills, planing-mills, iron-works, breweries, and wood-pulp factories, and exports timber (16,500,000 cubic feet annually), with iron and wood-pulp. In 1900 the exports amounted to about £1,000,000 in value, and the imports to £70,000. The port is cleared by some 400 to 500 vessels of 200,000 to 300,000 tons annually. In 1897 a new fairway was opened, giving access to vessels drawing 15 feet, *i.e.*, to the loading place at Branthäll. The port is, however, usually closed for the first four months of the year. The town, a straggling place with wide streets, was given municipal privileges by Gustavus Adolphus in 1620, and was rebuilt after fires in 1860 and 1865. Population (1880), 7937; (1900), 11,258.

Södertelge, a town of Sweden, county of Stockholm, stands on the Södertelge canal ($1\frac{1}{4}$ mile long; 10 feet deep on sill at low water; opened in 1819), which connects Lake Mälar with an inlet of the Baltic, 23 miles by rail west-south-west of Stockholm, of which it is indeed a suburb. It is frequented also as a summer resort, having mineral springs and baths. Its church is reputed to date from about 1100. There are engineering shops, jute spinning and weaving mills, match and joinery factories. Population (1880), 3510; (1900), 8207.

Soest, a town and episcopal see of Prussia, province of Westphalia, 33 miles by rail east of Dortmund. In front of the town hall (1701), which possesses valuable archives, stands a bronze statue of the Emperor William I. (1888). There are a teachers' seminary, a deaf and dumb and a blind asylum. Sugar is now manufactured. Population (1885), 14,846; (1900), 16,724.

Sofia, the capital of Bulgaria, finely situated on a high rolling plain 2000 feet above the sea and encompassed by the Balkan mountains, and at the terminus of the Sofia–Varna line (325 miles) opened in 1899, 300 miles west-north-west of Constantinople by rail, 206 miles south-east of Belgrade. By a branch line from Rustchuk joining the Sofia–Varna line near Tirnovo, improved means of communication is obtained with Berlin and north-east Germany, &c. The city is lighted by electricity, and there is an electric car system. Notwithstanding the bad harvests of several years, the commercial importance of the city is steadily increasing. It has breweries, tanneries, tobacco factories, and cloth and silk factories, and exports skins, cloth, cocoons, cereals, attar of roses, dried fruit, &c. The town was almost completely renovated during the last twenty years of the 19th century, the old town to the west, still partly inhabited by Turks, having been practically rebuilt in the European fashion. The houses are mainly brick encased in stucco, and the new town to the east dates entirely from 1878. A university was founded in 1888 (409 students in 1900), and there are colleges for boys and girls, a *real-schule*, a military school, and a military college. Near the cathedral in the old town is the mausoleum containing the remains of Prince Alexander of Battenberg. The Bujak-jami mosque is now occupied by the national library and the museum. Between the old and new town is the modern St Alexander Church, a magnificent structure in the Byzantine style, erected to commemorate the deliverance of Bulgaria. In the new town are the theatre, the fine university buildings, including the national printing establishment, the Chamber of Deputies, and monuments to the patriot Levski, to Russia, and to the Emperor Alexander II. of Russia. Population (1892), 46,593; (1900), 67,920, of whom two-thirds were Bulgarians and about one-sixth Jews.

Soignies, a town of Belgium, in the province of Hainaut, 11 miles north-east of Mons by rail. There are important freestone quarries in its vicinity, and sugar factories and tanneries. Population (1880), 8144; (1900), 10,124.

Sokota. See ABYSSINIA.

Sokoto, an important native state of the Central Sudan, now included in the British protectorate of Nigeria. The kingdom of Sokoto is the remnant of the great Fulbe kingdom established early in the 19th century by the leader Othman, but it has long been losing its importance as a military power, though the industrious and enterprising habits of the Hausas, who form the great bulk of its population, render it one of the most hopeful regions for the introduction of civilizing influences by Europeans. King Omar, under whose rule the power of the empire reached its lowest level, died in 1891, and was succeeded by Abderrahman, who has done something to restore the influence of the central power, especially by the reduction of the rebellious king of Argungu; but the once tributary states of Adamawa and Gando can no longer be considered as part of the kingdom. Adamawa itself is now split up into several quasi-independent sultanates, and its former capital, Yola, was taken by a British military expedition in 1901. The relations of Abderrahman with the British authorities have been somewhat doubtful, for though professing friendship, the king has shown himself unwilling to acknowledge the British protectorate; and in 1900 the expedition of Bishop Tugwell, though entirely non-political, was forced to retire from the great commercial centre of Kano owing to the suspicion of the native authorities. Under the administration, however, of Sir F. Lugard, the High Commissioner of Northern Nigeria, survey expeditions under Colonel Morland and other officers have reached Zaria, a strong walled town with an estimated population of 60,000 to 70,000, ruled by one of the most powerful vassals of the Sokoto kingdom, meeting with a cordial reception. By the Anglo-French agreement of 1898 the British "sphere of influence" is bounded, north of Sokoto, by a line leaving the Niger in about 11° 45′ N. and following the course of the Dallol Mauri to its intersection by the arc of a circle drawn from the town of Sokoto as a centre, with a radius of 100 miles. This is followed to its second intersection with the parallel 14° N., which then becomes the frontier for 70 miles, the line afterwards running south to 13° 20′ N. and east along this parallel for 250 miles, or beyond the limits of the Sokoto kingdom.

See MONTEIL, *De Saint-Louis à Tripoli par le lac Tchad*, Paris, 1895.—LUGARD. "Northern Nigeria," *Colonial Reports—Annual*, No. 346, 1902; and other works referred to under art. NIGERIA.

Sokotra.—This island is the largest and most easterly of a small group rising from a coral bank in the North Indian Ocean, of which Abd-el-Kuri, the Brothers (Kal Far'un, Semha, and Darzi), and Saboynea are the other members. An investigation of the island was undertaken by Professor Bayley Balfour in 1880, and subsequent expeditions were headed by Drs Riebeck and Schweinfurth in 1881, by Mr Theodore Bent in 1897, and by Dr H. O. Forbes and Mr Ogilvie-Grant (who also visited Abd-el-Kuri) in 1898–99. Simultaneously with the latter, a further expedition, conducted by Professor D. H. Müller, under the auspices of the Imperial Academy of Sciences of Vienna, visited Sokotra, Abd-el-Kuri, and some of the other islets of the group specially to investigate their geology and languages, but their report had not yet been published in 1902.

From the sea the island has an imposing appearance. The centre culminates in a series of rugged pinnacles—the Haghier mountains, which attain an altitude of nearly 5000 feet, rising out of and above a high (1500 feet) abutting and undulating limestone plateau, deeply channelled by valleys. At many parts of the

north coast the edges of this plateau reach the shore in precipitous cliffs, but in others low plains, dotted with bushes and date-palms, front the heights behind. The southern shore is bordered for nearly its entire length by a belt of drifted sand, forming the Nuget plain. Along this side of the island there are few villages and but one or two possible anchoring grounds, and these only during the north-east monsoon. On the north coast there are no harbours; but fairly safe anchorages, even in the north-east winds, are available off Hadibu or under Haulaf, a few miles distant, and at Kallansayia, at the north-west extremity of the island. Kállansayia, Khadup, and Hadibu, all small villages, are the only places of importance in Sokotra. The latter, the capital, is pleasantly situated amid date-palms in a semicircular plain enclosed by spurs of the Haghier mountains. As to the geology of the island, its fundamental rocks are gneisses, through which cut the felspathic granites which form the Haghier *massif*. Through these, again, pierce other granites in dykes or lava flows, and overlying the whole are limestones of Cretaceous and Tertiary age, themselves cut through by later volcanic eruptions. "In the Haghier hills," to quote Professor Bonney, "we have probably a fragment of a continental area of great antiquity, and of a land surface which may have been an 'ark of refuge' to a terrestrial fauna and flora from one of the very earliest periods of this world's history."

From October to May the weather is almost rainless, except in the mountains, where there are nightly showers and heavy mists. During this season the rivers, which are roaring torrents throughout the monsoon, are almost all lost in the dry, absorbent plains before reaching the sea. The temperature of the coastal area varies from 65° F. in the night to 85° F. in the day—in the hot season it may reach 95° F.; and on the mountains (3500 feet), from 52° F. to 72° F. In the low grounds fever of an acute and hematuric form is very prevalent.

Sokotra has claims to be reckoned one of the most ancient incense-supplying countries. Among the "harbours of incense" exploited by various Pharaohs during some twenty-five centuries, it is impossible to believe that the island could be missed by the Egyptian galleys on their way to the "Land of Punt," now identified with Somaliland; nor that, though the roadsteads of the African coast were perhaps oftener frequented, and for other freights besides myrrh and frankincense, the estuaries of Sokotra were neglected, by such ardent explorers as those, for instance, of Queen Hatasu of the 18th dynasty. They would have found on the island, which is probably referred to under the name "Terraces of Incense" (from its step-like contours), the precious "auta trees"—whose divine dew, for use in the service of their gods, was their special quest—in greater abundance and in a larger number of species than any other country.

The ancient trade of Sokotra—aloes, myrrh, frankincense, and dragon's-blood—has greatly declined. It consists now chiefly of *ghi*, or clarified butter from the milk of the large herds of goats and cows domesticated all over the island. It is exported to Zanzibar, Arabia, and Bombay. With the exception of a few patches of millet, tobacco, and cotton, cultivation is unknown. The country forms part of the sultanate of Kishin, in South Arabia. Its governor (usually also called sultan) exercises a mild authority beyond collecting the revenue obtained by a tax on all products. The people live mainly on milk and dates, diversified occasionally by flesh. The population, which may (with some hesitation) be given at about 10,000, is composed of two, if not more, elements. On the coast the people are modern Arabs mixed with negro, Indian, and other blood; in the mountains live the true Sokotri, the indigenes of the island, supposed to be originally immigrants from Arabia, who have been isolated here from time immemorial. Some of them are as light-skinned as Europeans, tall, robust, thin-lipped, straight-nosed, with straight black hair; others are shorter and darker in complexion, with round heads, long noses, thick lips, and scraggy limbs, indicating perhaps the commingling of more than one Semitic people. Their manner of life is rude and simple in the extreme. Their dwellings are circular, rubble-built, flat, clay-topped houses, or caves in the limestone rocks. They are bigoted Mahommedans, yet they rarely or never perform any devotions, and though generally harmless and inoffensive, are disinclined to have dealings with "Kafirs." They speak a language allied to the Mahra of the opposite coast of Arabia. Both Mahra and Sokotri are, according to Dr H. Müller, daughter-tongues of the old Sabæan and Minæan, standing in the same relation to the speech of the old inscriptions as Coptic does to that of the hieroglyphics. The Sokotran tongue has been, he believes, derived from the Mahra countries, but it has become so differentiated from the Mahra that the two peoples can understand each other only with difficulty. Sokotri is the older of the two languages, and retains the ancient form, which in the Mahran has been modified by Arabic and other influences.

The biology of Sokotra has now been sufficiently well investigated to give a correct idea of its relationships. The fauna contains no indigenous mammals. A wild ass which roams the eastern plains, perhaps its oldest denizen, is probably of Nubian origin; while the domestic cattle, a peculiar, unhumped, small, shapely, Alderney-like breed, may be a race gradually developed from cattle imported at a distant period from Sind or Farther India. There are 67 species of birds known from Sokotra, of which 15 are endemic; of 22 reptiles, 3 genera and 14 species are peculiar; and of the land and fresh-water shells, to whose distribution great importance attaches, 44 species out of 47 are confined to the island. Among the other invertebrate groups there is also a large proportion of endemic species. The flora is even more peculiar than the fauna. Aloes, dragon's-blood (*Dracæna*), myrrh, frankincense, pomegranate, and cucumber (*Dendrocycios*) trees are its most famous species. The phanerogams number 570, apportioned to 314 genera, and of these over 220 species and 98 genera are unknown elsewhere. The flora and also (though to a less degree) the fauna present not only Asian and Central African affinities, but, what is more interesting, Mascarene, South African, and Antipodean-American relationships, indicating a very different distribution of land and water and necessitating other bridges of communication than now exist. The history of Sokotra, unravelled by the study of its geology and biology, has been summarized by Professor Balfour as follows: "During the Carboniferous epoch there was in the region of Sokotra a shallow sea, in which was deposited, on the top of the fundamental gneisses of this spot, . . . the sandstone of which we have such a large development in Nubia. . . . During the Permian Sokotra may have been a land surface, forming part of the great mass of land which probably existed in this region at that epoch, and gave the wide area for the western migration of life which presently took place, and by which the eastern affinities in Sokotra may be explained. In early and middle Tertiary times, when the Indian peninsula was an island, and the sea which stretched into Europe washed the base of the Himalayan hills, Sokotra was in great part submerged and the great mass of limestone was deposited; but its higher peaks were still above water, and formed an island, peopled mainly by African species—the plants being the fragmentary remains of the old African flora—but with an admixture of eastern and other Asian forms. Thereafter it gradually rose, undergoing violent volcanic disturbance."

By this elevation "Madagascar would join the Seychelles, which in turn . . . would run into the larger Mascarene Islands. In this way, then, Africa would have an irregular coast-line, prolonged greatly south of the equator into the Indian Ocean, and running up with an advance upon the present line until it reached its north-west limit outside and south of Sokotra. Thence an advanced land surface of Asia would extend across the Arabian Sea into the Indian peninsula." Sokotra thus "again became part of the mainland, though it is likely for only a short period, and during this union the life of the adjacent continent covered its plains and filled its valleys. Subsequently it reverted to its insular condition, in which state it has remained." The Antipodean American element in the Sokotran flora probably arrived *viâ* the Mascarene Islands or South Africa from a former Antarctic continent.

AUTHORITIES.—JAMES JACKSON. "Sokotra: Notes Bibliographiques," in *La Revue de Géographie*, Paris, 1892, gives a very complete bibliography up to that date. *Bulletin of the Liverpool Museums*, vols. ii. and iii., 1899 1900. *Geographical Journ.*, London, 1899, vol. xiii. pp. 633, 638. (H. O. F.)

Soleure, one of the Swiss cantons. Its area is 305½ square miles. Of this, 298 square miles are reckoned as "productive," 112½ square miles being covered by forests, and ·3 square miles by vineyards, the remaining 185·2 square miles being arable or meadow land. The population was 80,362 in 1880 and 85,621 in 1888, while in 1900 it was 100,762. In 1900 there were 352 inhabitants per square mile. The people are mainly German-speaking, a comparatively few speaking French and still fewer Italian. Roman Catholics are in a decided majority, their proportions to Protestants being roughly as 3 to 1.

In 1897 the cantonal revenue was 2,265,087 francs (a rise of 39 per cent. since 1885) and the expenditure 2,258,339 francs (a rise of 31⅔ per cent. since 1885), while in 1898 the surplus was 11,182 francs. In 1897 the public debt was 9,813,000 francs. The existing political constitution dates from 1887, while in 1895 proportional representation was introduced as regards the elections to the cantonal legislature. The principal changes are that the executive is now elected direct by the people, while both its members and those of the legislature hold office for four years only. The "Obligatory Referendum" and the "Initiative" as regards laws date from 1875, and the Initiative as to amendment of the cantonal constitution from 1856. The canton is divided into 5 administrative districts. In 1888 the capital, Soleure, had 8317 inhabitants (of whom 5612 were Roman Catholics, a number

increased in 1900 to 10,095; while Olten in 1888 had 4899 (3009 Roman Catholics), and in 1899, 6996. In 1896 the pastures of the canton were 209, of an estimated capital value of 2,395,215 francs and capable of supporting 4179 cows.

Stadtverfassung von S.* Basel, 1897.—STROHMEIER. *Der Kant. S.* St Gall and Bern, 1836.—STRÜBY. *Die Weidewirthschaft im Kant. S.* Soleure, 1896. (W. A. B. C.)

Solingen, a town of Prussia, in the Rhine province, 20 miles north-north-east of Cologne by rail. It is the centre of the cutlery manufacture of Germany. Dorp was incorporated with it in 1889. Population (1885), 31,926; (1900), 45,249.

Solola, chief town of a department of Guatemala, Central America, picturesquely situated on a lofty plateau on the northern shore of Lake Atitlan, 46 miles west-north-west of Guatemala. It is the ancient capital of the Cakchiquel Indians, whose descendants are still its chief inhabitants. It has manufactures of cloth and potteries. Population, 12,000.

Somaliland, a country of East Africa, so named from its Somal inhabitants. It is also known as the "Eastern Horn of Africa," because it projects somewhat sharply eastwards into the Indian Ocean, and is the only section of the continent which can be at all spoken of as a peninsula. In general outline it presents the appearance of an irregular triangle, with apex at Cape Guardafui, which is the easternmost point of the continent, and is continued seawards through a line of reefs and rocks to the island of Sokotra. From the apex the north side extends for over 600 miles along the south shore of the Gulf of Aden westwards to Tajura Bay, and the east side skirts the Indian Ocean for about 1400 miles south-westwards to the mouth of the Juba river at the equator, while the less clearly marked base merges gradually landwards in the Ethiopian uplands between the equator and Tajura Bay. The vast triangular space thus roughly outlined has a total area which is approximately estimated at over 400,000 square miles, with a population of about 1,250,000, and has (1884–97) been partitioned by various international agreements between Great Britain, Italy, France, and Abyssinia as under:—

	Area in Square Miles.	Population.
British Somaliland:		
1. North Coast Protectorate .	68,000	200,000
2. South Somaliland attached to British East Africa .	100,000	250,000
French Somaliland . . .	50,000	100,000
Italian Somaliland . . .	100,000	400,000
Abyssinian Somaliland . .	100,000	300,000
Total . . .	418,000	1,250,000

Although the country had been visited at various points by a few travellers, such as Speke, Burton, Cruttenden, Révoil, and van der Decken, it was still practically an unknown land until the early 'eighties. But its systematic exploration, begun in 1883 by James Aylmer and Lort Phillips, has since made steady progress, and before the close of the 19th century the whole region had been traversed in several directions by Bottego, Ruspoli, Swaine, Cavendish, Donaldson Smith, Parkinson, Pease, Wickenburg, and Léontieff. Much no doubt remains to be done, and extensive tracts, especially west of the lower Juba, have not yet been even visited. But nothing of importance is left to be discovered by future travellers: the course of all the large rivers has been fairly accurately determined; many points in the interior have been astronomically fixed, and the main geographical features of the land clearly mapped out.

Physical features.

From the rough surveys made in various places, it appears that the whole region is characterized by a remarkable degree of physical uniformity, and may be broadly described as a vast plateau of moderate elevation, which is enclosed westwards by the Ethiopian highlands and northwards by an inner and an outer coast range, skirting the south side of the Gulf of Aden in its entire length from the Harrar uplands to Cape Guardafui. In the interior the plateau is nowhere traversed by any great mountain ranges, and everywhere presents the same monotonous aspect of a boundless steppe clothed with a scanty vegetation of scrubby plants and herbaceous growths.

The incline is uniformly in the direction of the south-east, and apart from the few coast streams that reach the Gulf of Aden during the rains, all the running waters are collected in three fluvial arteries—the Nogal in the north, the Webi Shebeli in the centre, and the Juba in the south—which have a parallel south-easterly direction towards the Indian Ocean. But so slight is the precipitation, the mean annual rainfall scarcely exceeding 8 or 10 inches, that the Juba alone has a permanent discharge seawards. The Nogal sends down a turbulent stream during the freshets, while the Shebeli, notwithstanding the far greater extent of its basin, never reaches the sea at all. At a distance of about 12 miles from the coast it is intercepted by a long line of dunes, which it fails to pierce and is thus deflected southwards, flowing in this direction for nearly 170 miles parallel with the coast, and then running out in a swampy depression before reaching the Juba estuary. The plateau appears to consist technically of a huge mass of Archæan rocks, mainly gneisses and schists, on the profoundly eroded surface of which have been deposited extensive sedimentary beds of Cainozoic age and eruptive matter of various dates, but all post-Jurassic. Limestones and sandstones prevail in many places, and the limestones of the lower Juba valley are believed to be part of a band which once extended from the Jurassics of British and German East Africa to those of Abyssinia. The Somali gneisses are similarly connected with the typical Archæan series of East Africa. The continuity of these geological systems was probably interrupted in Jurassic times, when the Somaliland plateau, without having ever been below the sea, was sufficiently depressed to allow the marine waters to penetrate, as a strait, far inland between the Eastern Horn and the Mau tableland to the south-east of Lake Rudolf. For details of climate, natural history, and other features, see British and Italian Somalilands below; and for the general characteristics and social institutions of the inhabitants, see article SOMÂLI in the ninth edition.

Inhabitants.

From the explorations of Mr Seton-Karr and others, Somaliland would appear to have been undoubtedly inhabited by primitive man of the early Stone period. His rude flint implements, of the same types as those occurring in Egypt, Mauritania, and Europe, have been found in various parts of the British protectorate, and according to some observers their manufacture has survived down to comparatively recent times. Other, but much later, remains are the round tumuli of undressed stone, generally 10 feet in circuit and 10 feet high, which are locally called "Galla graves," although also met with in the Beja country north of Abyssinia, where no Gallas are known to have ranged. Whether the present inhabitants of the land are the direct descendants of the forgotten race by which these monuments were erected it is impossible to say. But in any case they may claim a very long pedigree, for they have been identified beyond reasonable doubt with the people of Punt already known to the Egyptians of the early dynasties. They were in fact ethnically allied to those historic Egyptians, both being members of the vast Hamitic family, which may be regarded as the absolutely indigenous element in the whole of Africa north of the Negro domain. Together with the kindred Gallas, Afars (Danakil), Agaus, Bejas, and Egyptians, the Somali constitute the Eastern or Ethiopic branch of the Hamitic stock, and their languag is shown to be a

branch of the widespread Hamitic linguistic family. (See AFRICA: *Ethnology*.) But the present Somali peoples are not pure Hamites by any means, and the physical characters vary considerably according as the race has in course of ages been affected by contact at different points with the surrounding populations—Arabs, Abyssinians, Afars, Gallas, Bantus, and Negroes. Nevertheless, viewed as a whole, and despite a distinctly dark complexion everywhere conspicuous though varying in degree, they may be fairly described as one of the very finest groups of Caucasic man, tall of stature, with graceful pliant figures, regular and often extremely handsome features far above the average European type.

The Somali have no kind of political or even social cohesion, and are still divided into a multiplicity of *rers* or *fakidas* (tribes, clans), which are further complicated by manufactured genealogies, vague traditions, and legendary matter often inspired by the vanity or ambition of powerful chiefs. Hence all attempts at classification have hitherto failed; and even the schemes prepared by Major Abud, although possessing semi-official sanction, are not only very incomplete, but also in places untrustworthy. Three main divisions, however, have been clearly determined, and these are important both on political and ethnical grounds:—I. The HASHIYA (Abud's *Asha*), with two great subdivisions: *Daroda*, with the powerful Mijertins, War-Sengeli, Dolbohanti, and others; and *Ishak*, including the Gadibursi, Issa (Aissa), Habr-Awal, Habr-Tol, Habr-Yuni, Babilli, Bertiri. All these claim descent from a chief "Arab" by name, a member of the Hashim branch of the Koreish (Mahommed's tribe), who came over in the 12th century and founded a powerful but evanescent empire, with capital at Meit, in the Zeila district. All are Sunnites, and, although still speaking their Somali national tongue, betray a large infusion of Arab blood in their oval face, somewhat light skin, and remarkably regular features. Their domain comprises the whole of the British North Coast, and probably most of the Italian East Coast, Protectorates. II. The HAWIYA, with numerous sub-groups, such as the Habr-Jalet, Habr-Gader, Rer-Dollol, Daji, Karanlé, Badbadan Kunli, Bajimal, and Ugass-Elmi; mostly fanatical Mahommedans forming the powerful Tarika sect, whose influence, like that of the Wahabites formerly in Arabia, is felt throughout all the central and eastern parts of Somaliland. The Hawiya domain comprises the Ogaden plateau and the region generally between the Webi-Shebeli and Juba rivers. Here contact has been chiefly with the eastern Galla tribes, with whom political alliances have even been contracted. III. The RAHANWIN, with numerous but little known sub-groups, including, however, the powerful and warlike Abgals, Barawas, Gobrons, Tuni, Jidus, and Kalallas, occupy a vast domain extending from the Juba to the Tana, where they have long been in contact, mostly hostile, with the Wa-Pokomo and other Bantu peoples of the East Africa Protectorate. Hence of all the Somali divisions the Rahanwin betray the largest infusion of negroid blood, as shown in their flat features, small nose, and very dark complexion.

SOMALILAND, BRITISH.—For some years before the Mahdist revolt the whole of the North Somali coastlands had been included in the khedival possessions. Several stations, such as Zeila, Bulhar, and Berbera, as well as Harrar, at the converging point of the Abyssinian, Galla, and Somal territories, were held by Egyptian garrisons. But in 1884 all these garrisons had to be withdrawn, being needed for the defence of the Egyptian frontiers already threatened by the Mahdi's forces. It was then that Great Britain interfered, and, partly to save the country from relapsing into barbarism, partly to prevent its occupation by other Powers, by which the overland route to the East might be menaced, took possession of the vacated stations along the north coast nearly as far as Cape Guardafui. Thus was constituted the present "Somali Coast Protectorate," which was recognized by all the other interested Powers, and delimited by various international conventions, such as the Anglo-French agreement of 1888, the Anglo-Italian treaties of 1891 and 1894, and the arrangement of 1897 with Abyssinia, full details of which are given below under *French* and *Italian* SOMALILAND, and also under ABYSSINIA. It is important to notice that under the Italian treaty of 1894 Great Britain reserved the southern section of the Somali seaboard between the Juba and the Tana rivers, but included that region which extends inland as far as Logh on the Juba, not in the Somali Coast Protectorate, but in the East Africa Protectorate between Uganda and the Indian Ocean. Thus is explained the statement that the whole of the Somal territory under British rule, for which there is no collective official name, is very much larger than the northern section known as the Coast Protectorate. Before 1897 this protectorate had a total area of only 75,000 square miles, and was further reduced to 68,000 square miles when certain western tracts were ceded to Abyssinia in that year. The north-western boundary no longer reaches Gildessa, near Harrar, as formerly, but is marked in this direction by the Somadu heights, on the Anglo-French frontier. The vast central plateau of Ogaden is also ceded to Abyssinia, which, however, has hitherto failed to maintain order amongst the fanatical Moslem natives of this region, as shown by the outbreak of 1901, which had to be suppressed by a British force ascending the river Juba from the East Africa Protectorate. On the north side the Somali Coast Protectorate extends along the Gulf of Aden for a distance of about 400 miles from the Lahadu Wells, near Jibuti, in the west, to Bandar Ziyada, 4 9° E., some miles west of Cape Guardafui, and stretches from the coast inland for a mean breadth of perhaps 200 miles. A considerable number of the inhabitants (about 50,000) are settled in the coast towns, and as all the rest are pure nomads, with camping-grounds but scarcely any permanent inland stations, the total population would appear to fall short of 250,000.

Physical features.

Physically the protectorate has a distinctive character, and may be described as almost mountainous in contrast with the somewhat monotonous plains of the interior. Between the Harrar plateau and Cape Guardafui the coast ranges maintain a mean altitude of from 4000 to 5000 feet, and fall generally in steep escarpments down to the narrow strip of sandy lowlands skirting the Gulf of Aden. At some points the rugged cliffs, furrowed by deep ravines, approach close to the sea; elsewhere the hills recede abruptly inland, leaving a considerable maritime plain between their base and the shore line. South of Berbera, which faces Aden on the opposite side of the gulf, are developed two ranges which run nearly parallel with the coast, and increase in elevation landwards, culminating in the inner and loftier range in the Gan Libash ("Lion's Paw"), about 9500 feet high. Southwards the slopes fall somewhat gently towards the central plains, which are at first dotted with a few clumps of mimosa, and farther on present the aspect of an interminable treeless steppe. Eastwards the mountain system maintains the same general character as far as Bandar Gori, where the precipitous northern cliffs approach to within 200 or 300 yards of the gulf, their bare brown rocks and clays presenting the same uninviting appearance as the light brown hills skirting the Red Sea. But in the valleys between the two parallel ridges, which here stand at an altitude of from 6000 to 7000 feet, the dreary aspect of the coast scenery is succeeded by a relatively rich vegetation of bush, jungle, and herbage, with a luxuriant growth of gummiferous and aromatic plants. Low trees and jungle range to a considerable height above the valleys on the northern slopes of the inner range, which here falls in a series of terraces down to the Wady Nogal. The prevailing formations appear to be granites which are veined with white quartz, and underlie old sedimentary brown sandstone and limestone formations. There are no traces of recent igneous disturbances, but old erupted matter occurs at intervals, and the volcanic heights, as well as the general character of the ranges, resemble those of the South Arabian uplands on the opposite side of the gulf.

Climate, flora, fauna.

The climate also is much the same—dry and hot, with but slight changes from season to season. Thus on the coast the winter temperature ranges from 75° to 80° F., while that of summer rarely exceeds 86° F., the extreme deviation for the whole year being little more than about 20° F. Although the protectorate lies within the track of the north-east monsoons dominant from October to March, the currents are so frequently deflected from their normal course by changes of barometric pressure or temperature that the winter rains are seldom copious. But the summer monsoons prevalent from April to July or August are often accompanied by fierce hurricanes and tremendous downpours, by which the sparse vegetation is revived, while the usually waterless wadys are for the time transformed to raging coast torrents. But the mean annual rainfall, thus unevenly distributed, probably falls below 30 inches, and is also largely confined to the slopes of the ranges by which the moisture-bearing clouds are intercepted. As in South Arabia, these slopes are the proper home of the aromatic flora which yields the myrrh and frankincense of commerce, and for which these

regions have been famous throughout historic times. Highly characteristic are the *Olibanum*, a member of the *Boswellia* genus, from which are obtained odoriferous resins in abundance, and the *Balsamodendron Myrrha*, which exudes a gum resin in round masses called "tears," varying in size from small grains to lumps as large as an egg, and of a semi-transparent reddish-brown colour. On the plains, which receive a minimum supply of moisture, little flourishes except a poor scrubby flora of thorny acacias and mimosas scattered thinly over wide areas. The coast districts have been so frequently visited by sportsmen in recent years that most of the characteristic wild fauna have withdrawn farther inland. Nevertheless lions, leopards, hyænas, wild asses, gazelle and other antelopes, jackals, the dog-faced ape, and even elephants, are still met in the more remote districts. Hares and other rodents are common on the coastlands, which are also enlivened by the jumping-shrews, which at a little distance look exactly like diminutive kangaroos hopping about in search of the insects on which they prey. The lizard family is represented by the *Agama Rüppellii*, which changes colour when pursued, and by the still more curious *Uromastix batilliferus*, another species of Agama which disappears in the clefts of the rocks, leaving nothing to be seized except the tip of a tail bristling with sharp spines. The Somali have little knowledge of the horse, which appears to be of recent introduction, and their chief domestic animals are the camel and the ass, both of prime stock. The camels make excellent mounts, swift and hardy; and the extensive caravan trade is everywhere carried on exclusively by means of these pack-animals, the natives being too proud to be treated as beasts of burden, like their Bantu and Negro neighbours.

Chief towns.

In the northern coastlands most of the Hashíya "sultans" have already accepted the British protectorate, which affords them the best security for the stability of their power. They are beginning to call themselves "British subjects," and show a growing disposition to submit their incessant tribal wranglings to the British authorities at Berbera. This place, which is said to have been founded by the Ptolemies amongst the "Barbari" of the surrounding coastlands, is the capital and chief seaport of the protectorate. It is by far the largest centre of trade and population in the whole of Somaliland, with a population in the trading season of about 30,000. Berbera stands at the head of a deep inlet, which forms the only sheltered haven on the south side of the Gulf of Aden. Recently extensive harbour works have been completed, and there are now two lighthouses, piers, warehouses, a strong fort, hospital, barracks, and an aqueduct seven miles long, which supplies the town with a copious stream from the neighbouring hills. About 45 miles farther west is the exposed port of Búlhar, which, however, is conveniently situated for the caravan trade. It has a permanent population of 12,000, and the district yields an abundance of good pasture. Close to the French frontier on the same coast stands the flourishing seaport of Zeila, with a present population of 15,000. It has been proposed to construct a railway from this place, or from Búlhar, through Harrar to Abyssinia. But these projects seem to have been suspended by the rapid execution of the line running from Jibuti through French territory in the same direction.

The protectorate, which since 1884 had been attached for administrative purposes to the government of Bombay, was constituted a Crown colony in October 1898. In 1900 the revenue and expenditure were Rs.3,85,884 and Rs.3,40,092 respectively; the imports (Berbera and Búlhar) Rs.33,15,651, (Zeila) Rs.34,71,904; the exports from same places, Rs.28,71,902 and Rs.30,12,712. The imports are chiefly rice, piece-goods, shirtings, and dates; the exports skins and hides, ostrich feathers, gums, civet, cattle, and sheep.

SOMALILAND, FRENCH, a possession of France on the Gulf of Aden, at the entrance to the Red Sea. Its limits are Ras Doumeira, on the strait of Bab el Mandeb, and Ras Goumarlé, between Zeila and the Gulf of Tajura. This coast is arid, and on the south is bordered with plains 500 feet high, but inland there are some cultivated spots on marshy ground. The territory is about 40 miles long and 125 broad, with a population estimated at about 22,000. The climate is very hot. The port of Obock, one of the centres of this possession, was bought from Turkey in 1855 for £2000 by M. Lambert, then French consul at Aden. The acquisition was ratified in 1861, after a journey by Admiral Fleuriot de Langle. A French factory was erected at the port in 1881, and depôts for victuals and coal for war-vessels were installed in 1883. In that year Sagallo was ceded to France; in 1884, Tajura; and in 1885, Ambabo. In 1887 the territory was delimited by agreement with Great Britain; and in 1888 a port was created at Jibuti, whither the administrative services were transferred, and the commencement of the works on the railway to Harrar conferred real importance on the place. The expenditure of France on the Somali coast (budget of 1900) was 337,500 francs. The local budget for 1899 balanced at 650,000 francs. The colony of Obock, together with the protectorates of other districts, is administered by a governor, who resides at Jibuti. The centres of population are Jibuti (15,000 inhabitants, of whom 2500 are Europeans), Obock, Sagallo, Tajura (2000), Ambabo, and Gobad. The native population is either of the Danakil or of the Galla race. The produce of the soil is almost *nil*. On the coast, turtle and mother-of-pearl fishing are carried on. The country exports mother-of-pearl, gum, coffee, emery, hides, ivory, and gold. The prosperity of Jibuti is due to its position at the head of the best route towards Harrar and Addis Ababa, but it will not be real until the railway is completed. In January 1902 the first 125 miles of the railway from Jibuti to Harrar were open for traffic. At the distance of 340 miles north of Obock, on the Red Sea, is the Bay of Adulis, ceded to France under the Second Empire by Tigre, but not occupied.

SOMALILAND, ITALIAN.—By various arrangements with native sultans in 1889 the African coast as far as Cape Guardafui to the north, and as far as Bandar-Siyada (49° E.) on the Gulf of Aden, fell within the Italian sphere of influence. On 19th November 1899 the Italian Government notified the Powers that it had assumed the protectorate over the East African coast from the northern limit of the territory of Kismayu (0° 14′ 30″ S., 42° 38′ 50″ E.) to 2° 30′ N. for the stretches recognized as intermediate between the stations belonging to the Sultan of Zanzibar. Finally, by a treaty dated 12th August 1892, the Sultan of Zanzibar made over to Italy for a term of fifty years, and in exchange for an annual payment of Rs.160,000 (subsequently reduced to Rs.120,000), all his rights over the ports of Barava, Marka, Mukdishu, and Warsheikh. In pursuance of this treaty and of the Anglo-Italian protocol dated 24th March 1891, the East African littoral from the Juba valley to Bandar-Siyada was recognized as an Italian sphere of influence, under the name of Italian Somaliland. Towards the interior the boundary of this sphere followed the course of the Juba as far as 6° N., and thence coincides with that parallel as far as 35° E., and with the 35th meridian up to the point where it intersects the Blue Nile. On the Gulf of Aden the internal frontier is marked by a line which, starting from Gildessa and proceeding towards 8° N., follows the north-eastern limits of the Girri, Bertiri, and Rea Ali territories, including in the Italian sphere the villages of Yaldessa, Darmi, Gig-Giga, and Milmil. On reaching 8° N. the line coincides with that parallel as far as 48° E., whence it turns north-east to the point of intersection of the 9th parallel N. with the 49th meridian E. and follows the latter meridian to the sea at Bandar-Siyada (Anglo-Italian protocol of 5th May 1894). By the same protocol the port of Zeila and the station and territory of Kismayu were recognized as belonging to Great Britain, but equality of rights and treatment for British and Italian subjects was established. The

Italo-Abyssinian treaty, signed at Addis Abbaba in the summer of 1897, stipulated that the interior of Italian Somaliland should belong to Abyssinia up to within forty miles from the coast, and that the station of Lugh should be made over to the Negus.

Information concerning the interior of Italian Somaliland is scarce and uncertain. To the north it is inhabited by the Ogaden Somali, and to the south by the Arusi and the Boran, which are more properly classified as Galla tribes. The soil, which rises rapidly in successive plateaux from the sea, is considered especially fertile in the great valleys of the Juba (Ganana), Webbi, and Wady Nogal, which, descending from the Ethiopian Alps, traverse the country from north-west to south-east. In other districts lack of water impedes cultivation, though after the rains pasturage is abundant, and resinous plants are so varied and numerous as to justify the ancient name. The climate on the plateaux is temperate and healthy, but near the streams malaria and enteric fever prevail. The temperature in the interior oscillates between 60° and 86° Fahr., but along the coast rises to 104°. Continual breezes, however, render this temperature tolerable for Europeans. Along the coast live a number of Arabs and several tribes of mixed Arabo-Somali blood, of which the Amaran tribe is the principal. These Arabs are a residuum of the dominion of the Imam of Muskat, which lasted from 1698 to 1856. The languages spoken in Italian Somaliland are Arab, Somali, and Suaheli. The Somali profess the Mussulman religion, but do not strictly interpret the injunctions of the Koran.

The chief towns of Italian Somaliland are: *Brava*, with about 4000 inhabitants, belonging for the most part to tribes of the interior. It was destroyed in 1840 by Ibrahim of Bardera and repeopled by Sheikh Yusuf, who in 1843 invaded Bardera, razing it to the ground and putting its inhabitants to the sword.

Marka (Merca), situated at 1° 42′ 05″ N., 44° 53′ 50″ E., with about 5000 inhabitants, and a trade from the interior in cotton, coffee, maize, butter, and skins.

Mukdishu (Mogadishu), 2° 01′ 50″ N., 45° 24′ 40″ E., is formed of the villages of Shangani and Hamerain, which together number 6000 inhabitants. An ancient tower recalls Portuguese rule (1529–1698). In the neighbourhood gold and silver objects have been found, together with money and domestic utensils, which bear witness to an ancient civilization long since swept away.

Warsheikh, 2° 19′ 45″ N., 45° 53′ 50″ E., has about 3000 inhabitants. A natural channel allows ships of all sizes to approach to within 700 or 800 yards of the coast, but the bay is only practicable during the north-east monsoon.

Itala, a station established by Captain Filonardi, in the belief that it was a good port, but subsequently abandoned.

Obbia, 5° 22′ N., 48° 30′ E., residence of Sultan Yusuf Ali Yusuf, and *Alula*, residence of the Sultan Osman Mahmud, are two large villages, well kept, and inhabited by tribes which are distinguished from other Somalis by the mildness of their disposition. Considerable trade in ostrich feathers is carried on.

Along the coast are to be noted the minor villages of Coriale, Gondersha, Gellib, Akari, Galwin, Gelidi, Torre, Munghia, &c., and the station of Yub (Yumbo), at the mouth of the Juba. In the interior is situated *Lugh*, a populous city on the left bank of the Ganana, about 240 miles from the coast; visited for the first time by Captain Bòttego in 1893. The Sultan of Lugh applied for Italian protection in June 1895, but the city and territory are still a subject of contention between Italy and Abyssinia. For the time being Italians and Abyssinians enjoy parity of treatment there.

Benadir Company. The part of Italian Somaliland known as *El Benadir* (the ports), comprising Yub, Brava, Marka, Mukdishu, and Warsheikh, was ceded for three years to the Filonardi Commercial Company by way of experiment. In 1896 the Italian Benadir Trading Company Limited (Società Anonima Commerciale Italiana del Benadir), formed at Milan with £40,000 capital, should have replaced the Filonardi Society in the administration of the Benadir coast; but on 26th November 1896 the Italian consul, Captain Cecchi, who was preparing to inaugurate the new régime, was killed in an ambush at Lafolè, and the consequent disturbances hindered for a time the installation of the new company. On 1st May 1898 the Italian Government, however, concluded a convention with the Benadir Company, granting to it the administration of the Benadir ports until 16th July 1946, with a subsidy of £16,000 annually for the first twelve years, and of £14,000 from 1910 until the expiry of the convention. The Government retained the option of denouncing the convention on 16th July 1921, subject to two years' notice. The company was given the right to collect taxes and customs, to exploit mines, to occupy territories in Italian possession, to obtain from Government arsenals at cost price the arms and munitions of war necessary for the safety of the colony, and to enjoy in the port of Kismayu all the facilities specified in the Anglo-Italian protocol of 24th March 1891 (Art. 3). The company for its part, undertook to develop the colony; to pay to the Sultan of Zanzibar an annual tribute of 120,000 rupees; to maintain at least 600 guards for the protection of the stations; to administer justice, respect existing laws and treaties, apply the provisions of the Berlin and Brussels Conventions, and to assume the postal service. The Italian Government explicitly declined to guarantee any operations of credit entered into by the company, or to consent that the convention with the company, or the privileges therein specified, be ceded to any third party. During the year 1896–97 the total value of the Benadir trade was £120,000, and since then it has continually increased. The chief imports are petroleum, rice, and textile fabrics; the exports are ivory, cattle, butter, cotton, dhurra, gum, myrrh, and skins.

See *L'Omo: Viaggio di esplorazione nell' Africa orientale, narrato da L. Vanutelli e C. Citerni.* Milan, 1899. (L. Me.)

Somersetshire, a south-western maritime county of England, is bounded on the E. by Wilts, on the N.E. by Gloucester, on the N. and N.W. by the Severn and the Bristol Channel, on the W. and S.W. by Devon, and on the S.E. by Dorset.

Area and Population.—The area of the ancient county is 1,043,485 acres, or 1630 square miles, with a population in 1881 of 469,109; in 1891 of 484,337, of whom 225,754 were males and 258,583 females; and in 1901 of 508,104; the number of persons per square mile being 312, and of acres to a person 2·05. The area of the administrative county, as given in the census returns of 1891, was 1,039,106 acres, with a population of 386,866, or, including the county borough of Bath, 1,042,488 acres, with a population of 438,760; but since then certain changes have been made in the administrative area. In 1895 the parishes of Goathill, Poyntington, Sandford Orcas, Seaborough, and Trent were transferred from Somerset to Dorset, the parts of the parishes of Maiden Bradley with Yarnfield and Stourton with Gaspar in Somerset to Wilts, and the parish of Wambrook from Dorset to Somerset; and in 1896 the parish of Church-Stanton was transferred from Devon to Somerset, and the parish of Kilmington from Somerset to Wilts. The area of the registration county is 1,061,614 acres, with a population in 1891 of 510,076, of whom 219,021 were urban and 291,055 rural, and in 1901 of 466,126, of whom 215,693 were males and 250,433 females. Within the registration area the percentage of increase between 1881 and 1891 was 3·84. The excess of births over deaths between 1881 and 1891 was 59,729, and the actual increase of population was 18,851. The following table gives the number of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1898:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Males.	Females.
1880	3163	15,033	8935	359	327
1890	3269	14,114	8909	252	265
1898	3686	14,064	8167	225	234

In 1899 the number of marriages was 3226, of births 11,386, and of deaths 7823.

The following table gives the marriage-, birth-, and death-rates per thousand of the population, with the percentage of illegitimate births, for a series of years:—

	1870-79.	1880.	1880-89.	1890.	1888-97.	1898.
Marriage-rate	13·3	12·9	13·0	12·9	13·4	14·1
Birth-rate	30·9	30·6	29·6	27·7	27·8	26·9
Death-rate	19·4	18·2	17·4	17·5	16·5	15·6
Percentage of illegitimacy	4·7	4·6	4·3	3·7	3·7	3·3

The birth- and death-rates and the percentage of illegitimacy are all below the average. In 1891 there were in the county 1484 natives of Scotland, 2234 natives of Ireland, and 1049 foreigners.

Constitution and Government.—The parliamentary and judicial arrangements remain as stated in the earlier article on the county. The administrative county includes seven municipal boroughs: the city of Bath (49,817 in 1901), Bridgwater (15,209), Chard (4437), Glastonbury (4016), Taunton (21,078), Wells (4849), and Yeovil (9838). Bath is a county borough. The following are urban districts: Burnham (2897), Clevedon (5898), Crewkerne (4226), Frome (11,055), Highbridge (2234), Ilminster (2287), Midsomer Norton (5811), Minehead (2511), Portishead (2544), Radstock (3365), Shepton Mallet (5238), Street (4018), Wellington (7282), Weston-super-Mare (19,047), and Wiveliscombe (1417). The ancient county, which corresponds closely with the diocese of

Bath and Wells, contains 501 ecclesiastical parishes and districts and parts of 3 others.

Education.—At Wellington there is a board school for blind children. The total number of elementary schools in the county on 31st August 1898 was 552, of which 106 were board and 446 voluntary schools, the latter including 410 National Church of England schools, 8 Wesleyan, 6 Roman Catholic, and 22 "British and other." The average attendance at board schools was 17,268, and at voluntary schools 46,224. The total school board receipts for the year ended 29th September 1898 were £67,590. The income under the Agricultural Rates Act was over £3576.

Agriculture.—Nearly five-sixths of the total area of the county is under cultivation, but about three-fourths of this is in permanent pasture, an exceptionally large number of cattle, especially cows, being kept, while many sheep are also grazed both on the lower grounds and the hill pasture, of which there are over 50,000 acres. Orchards, chiefly of apple-trees for cider, occupy 25,000 acres, and over 45,000 are under woods. The Exmoor district is still tenanted by wild deer, and there is also a special breed of ponies peculiar to the district. The acreage under corn crops has within recent years largely decreased. Wheat occupies about five-twelfths of this acreage, and barley and oats usually about one-fourth each, oats having the largest acreage of the two, Of the acreage under green crops, about one-half is occupied by turnips and swedes, about one-fourth by mangold, and about one-tenth by potatoes.

The following table gives the larger main divisions of the cultivated area at intervals from 1885 :—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1900	867,469	115,005	61,650	58,863	625,957	5434
1885	868,721	109,607	55,639	53,567	643,937	5112
1890	860,649	94,628	52,116	54,486	653,435	5045
1895	854,538	97,333	49,111	50,139	654,659	2615

The following table gives the numbers of the principal live stock for the same years :—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1885	34,848	236,899	110,068	601,020	111,719
1890	34,895	235,742	107,513	596,637	137,849
1895	37,693	221,117	104,111	538,757	140,857
1900	35,981	239,663	106,210	519,670	118,884

Industries and Trade.—According to the report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 37,164, as compared with 34,975 in 1896. Of these 4687 were employed in textile factories, woollen and worsted industries employing 1791, and linen, &c. (at Crewkerne, Taunton, and Shepton Mallet), 1096 ; there is now a considerable lace manufacture, chiefly at Chard. Non-textile factories employed 25,281 persons, the percentage of increase between 1895 and 1896 being 7·5, while between 1896 and 1897 it was 9·2. Of these, 2770 were employed in the manufacture of paper, &c., 8324 in clothing industries, 2553 in the manufacture of machines, &c. (including carriages, agricultural implements, spades, shovels, and edge tools), 2023 in tobacco and snuff industries, 1446 in clay and stone industries (including bricks, drain tiles, and the well-known bathbrick), 1227 in wood industries, and 1121 in drink industries. Of the 7196 persons employed in workshops, 3582 were employed in clothing industries. The total number of persons employed in connexion with mines and quarries in 1899 was 6864. The same year 480,158 tons of limestone were raised, 178,153 tons of clay, 58,910 tons of sandstone, 5970 tons of gravel and sand, 9866 tons of ochre, 5875 tons of gypsum, 1750 tons of slate, 475 tons of sulphate of strontia, and 9866 tons of manganese ore. Lead mining has now almost ceased. 921,870 tons of coal, valued at £464,776, were raised in 1890 ; 983,973 tons, valued at £541,185, in 1899.

The Bristol Channel and Bridgwater Bay abound in varieties of white and shell fish, and salmon and herring fishing are also carried on, the principal fishing stations being Porlock, Minehead, and Watchet ; but since in the return relating to sea fisheries they are not included amongst the fishing ports at which fish are landed, no statistics are available.

F. H)

Somersworth, a city of Strafford county, New Hampshire, U.S.A. It is situated in the south-eastern part of the state, on Salmon Falls river, which separates it from the state of Maine, and on the Boston and Maine Railroad. It has an excellent water-power in Salmon Falls river, and this is turned to account in extensive manufactures. Population (1890), 6207 ; (1900), 7023, of whom 3166 were foreign-born.

Somerville, a city of Middlesex county, Massachusetts, U.S.A. It is situated in 42° 22′ N., 71° 05′ W., on the river Mystic, adjoining Boston, of which it is a suburb, and with which it is connected by many lines of steam and trolley railways. Its streets are macadamized or gravelled. It is an active manufacturing city; the census of 1900 showed that it contained 378 manufacturing establishments, with a total capital of $10,131,596. They employed 4342 hands, and the product was valued at $21,776,511. Its assessed valuation in 1900 was $52,578,200, the net debt was $1,828,000, and the rate of taxation was $16 per $1000. Population (1890), 40,152; (1900), 61,643, of whom 17,232 were foreign-born and 140 negroes. Of 18,148 males 21 years of age and over, 490 were illiterate (unable to write).

Somme, a department on the north coast of France, taking its name from the river running through it from south-east to north-west.

Area, 2423 square miles. The population, 550,837 in 1881, numbered only 534,101 in 1901. The births in 1899 were 11,670, of which 1715 were illegitimate ; deaths, 12,832 ; marriages, 3989. With 1437 schools accommodating 78,000 pupils, primary grade, in 1896, 5 per cent. of the population was illiterate. The land under cultivation in 1896 measured 1,411,605 acres, of which 1,143,610 acres were arable. There are no vines in the agricultural returns of this department. The soil is considerably productive. Its wheat crop of 1898 amounted to the value of £1,540,000 ; meslin, £94,000 ; rye, £88,000 ; barley, £128,000 ; oats, £1,120,000 ; potatoes, £318,500 ; mangold-wurzel, £114,800 ; green crop (trefoil, lucern, and sainfoin), £401,800 ; apples, £43,500 ; garden-poppy, £43,500. Its beetroot produce was valued at £911,000. The live stock comprised (1899) 76,500 horses, 165,800 cattle, 380,900 sheep, 85,300 pigs, and 14,550 goats. Peat-cutting in 1898 amounted to 37,300 metric tons. The industry in metals produced only 3005 tons of iron, valued at £23,500. The thriving industries are the spinning and weaving of linen, hemp, and cotton. The velvets of Amiens are in good repute. Sugar-refining yielded (1899) 2,048,000 cwt. The product of the distilleries amounted to 5,830,000 gallons of alcohol. Amiens, the capital, had (1901) 90,038 inhabitants.

Sonderburg, a seaport and seaside resort of Prussia, province of Schleswig-Holstein, on the south-west coast of the island of Alsen, of which it is the chief town, and 17 miles by steamboat north-east from Flensburg. There is a castle, now used as barracks. The town, which existed in the middle of the 13th century, was burnt down in 1864 during the assault by the Prussians upon the Düppler trenches (on the mainland). Population (1900), 5522.

Sondershausen, a town of Germany, capital of principality Schwarzburg-Sondershausen, 37 miles by rail north of Erfurt. It possesses a castle, with natural history and antiquarian collections, and a parish church (restored 1891), with the mausoleum (1892) of the reigning princes. The people make pins and woollens. Population (1900), 7053.

Sondrio, capital of the province of Sondrio, Lombardy, Italy, amongst the Southern Alps, on the river Adda, 26 miles east of Lake Como, and 83 miles by rail

north-east of Milan. It is visited by tourists in spring and autumn, and has active silk industries and manufacture of stone pottery (*lavez*). There are a technical school and an industrial institute. Population (1901), 8700. In the Masino valley, 12 miles north-west of Sondrio, there are, at Ardenno, saline baths and springs, with a temperature of 86° Fahr.

Song-Koi, or Red River. See Indo-China.

Sonneberg, a town of Germany, duchy of Saxe-Meiningen, situated in a narrow valley of the Thuringian Forest, 13 miles by rail north-east of Coburg. It is famous for its manufacture of toys, papier-maché, mirrors, &c.; it has also tanneries, dyeworks, and slate works. The town possesses a fine Gothic church, a hydropathic, and a monument to the philologist Schleicher (1821–68). Population (1885), 10,247; (1900), 13,317.

Sonnino, Sidney, Baron (1847——), Italian statesman and financier, was born at Florence on 11th March 1847. Entering the diplomatic service at an early age, he was appointed successively to the legations of Madrid, Vienna, Berlin, and Versailles, but in 1871 returned to Italy, to devote himself to political and social studies. On his own initiative he conducted exhaustive inquiries into the conditions of the Sicilian peasants and of the Tuscan *métayers*. In 1878 he founded a weekly economic review, *La Rassegna Settimanale*, which four years later he converted into a political daily journal. Elected deputy in 1880, he distinguished himself by trenchant criticism of Magliani's finance, and upon the fall of Magliani was for some months, in 1889, Under-Secretary of State for the Treasury. In view of the severe monetary crisis of 1893, he was entrusted by Crispi with the portfolio of Finance (December 1893), and in spite of determined opposition, dealt energetically and successfully with the deficit of more than £6,000,000 then existing in the exchequer. By abolishing the illusory pensions fund, by applying and amending the Bank Laws, effecting economies, and increasing taxation upon corn, incomes from consolidated stock, salt, and matches, he averted national bankruptcy, and placed Italian finance upon a sounder basis than at any time since the fall of the Right. Though averse from the policy of unlimited colonial expansion, he provided by a loan for the cost of the Abyssinian war in which the tactics of General Baratieri had involved the Crispi Cabinet, but fell with Crispi after the disaster at Adowa (March 1896). Assuming then the leadership of the constitutional Opposition, he combated the alliance between the Rudini Cabinet and the subversive parties, criticized the financial schemes of the Treasury Minister, Luzzatti, and opposed the "democratic" finance of the first Pelloux administration as likely to endanger financial stability. After the modification of the Pelloux Cabinet (May 1899) he became leader of the ministerial majority, and bore the brunt of the struggle against Socialist obstruction in connexion with the Public Safety Bill. Upon the formation of the Zanardelli Cabinet (February 1901) he once more became leader of the constitutional Opposition, and in the autumn of the year founded a daily organ, *Il Giornale d'Italia*, the better to propagate Moderate Liberal ideas.

Sonora, a state of Mexico, bounded on the N. by the United States, on the E. by Chihuahua, on the W. by the Gulf of California, and on the S. by Sinaloa. Area, 76,922 square miles, being only exceeded by the state of Chihuahua (87,820). Population (1879), 115,424; (1900), 220,553. The principal agricultural products are cereals, tobacco, cotton, sugar-cane, fruits, &c. The annual value of the exports of minerals is from $10,000,000 to $12,000,000 (silver). The Guaymas and Nogales Railway connects the state with the Southern Pacific Railroad. The capital, Hermosillo, has 8474 inhabitants. Other towns include Alamos (6197), Guaymas, an important commercial port connected by rail with Nogales on the United States frontier, the terminal point of the Sonora Railway, Moctezuma or Oposura, Arizpe, Ures.

Sonpur, a feudatory state of India, in the Chhattisgarh division of the Central Provinces. Area, 906 square miles. Population (1881), 178,701; (1891), 195,245; (1901), 170,633, showing a decrease of 13 per cent., due to the results of famine. Estimated revenue, Rs.1,06,000; tribute, Rs.9000. The chief is a rajput of the Patna line. Rice and timber are exported, and iron ore is said to abound. The town of Sonpur is on the Mahanadi river, just above the point where it enters Orissa.

Sonthal (or Santal) **Parganas, The,** a district of British India, in the Bhagalpur division of Bengal. It stretches south from the Ganges at Rajmahal to Chota Nagpur, and consists mostly of a rolling, forest-clad plateau. Area, 5469 square miles. Population (1881), 1,567,966; (1891), 1,754,196, showing an increase of 12 per cent., partly due to more accurate enumeration; average density, 321 persons per square mile. In 1901 the population was 1,807.286, showing an increase of 3 per cent.

Classified according to religion, Hindus in 1891 numbered 900,399; Mahommedans, 121,086; Christians, 5943, of whom 196 were Europeans; aborigines, 726,284; "others," 481. The land revenue and rates in 1897–98 were Rs.3,31,744; number of police, 388; boys at school (1896–97), 20,667, being 15·7 per cent. of the male population of school-going age; registered death-rate (1897), 29 per thousand. The Sonthals, who give their name to the district, are the most numerous aboriginal tribe in Bengal, who work the coal-mines of Raniganj and Karharbari and migrate to the tea-gardens of Assam. According to the linguistic classification of the census of 1891, the total number of persons in India speaking Sonthali was 1,709,680. The Church Missionary Society and the Scandinavian Sonthal Home Mission have been very successful among them, especially in promoting education. The district is traversed by both the chord and loop lines of the East Indian Railway. It comprises the old Mahommedan city of Rajmahal and the modern commercial mart of Sahibganj, both on the Ganges; and also the Hindu place of pilgrimage of Deogarh, which is important enough to have a branch railway. Coal-mines yield about 1800 tons a year.

Soochow, or Suchau, the capital of the province of Kiangsu, China. It was opened to foreign trade by the Japanese treaty of 1895, but the privilege has not been largely utilized. Indeed, the value of the trade has steadily declined from an aggregate of 1,473,560 H. taels in 1897 to 1,176,616 H. taels in 1900. The only importance of the port is as a centre of distribution for foreign goods subordinate to Shanghai, with which it is connected by a canal 80 miles in length. The trade is entirely in native hands. A cotton spinning mill and two or three silk filatures have been erected, two of the latter in native hands, the others in part under European management. The principal industry in Soochow is silk-weaving. The fabrics produced are of extreme elegance and low price, and are chiefly intended for the domestic market in China; but there is a large and increasing demand for export (value of silk export in 1900, £72,000). In the ninth edition of this work Soochow was credited with a population of 500,000, but a more recent estimate would give about 350,000.

Sopron (Oedenburg), a municipal town in Hungary, capital of the county of the same name, 40 miles south by east of Vienna, with a population in 1891 of 29,543, and in 1901 of 33,478. It contains an evangelical school, 3 gymnasia, 2 upper *real*-schools, 2 training institutes for teachers, a commercial academy, several orphanages, &c.

Amongst its manufactures are bell-founding and machinery, besides sugar, beer, vinegar, soap, and a flourishing wine trade. The electric light and tramways are in operation.

Sorau, a town of Prussia, on the Sorebach, near the frontier of Silesia, 55 miles south-south-east of Frankfurt-on-Oder by rail. There are 7 churches and several schools, including a technical and a weaving school. The industries include cloth and linen factories. Population (1885), 13,668; (1900), 15,945.

Sorel, a city and port of entry of Quebec, Canada, capital of Richelieu county, 42 miles north-east of Montreal, at the confluence of the Richelieu and St Lawrence. It is a station on the Quebec Southern and South Shore railways, and is a port of call for the Montreal and Quebec river steamers. It contains iron and leather manufactories, and shipbuilding is carried on. It occupies the site of a fort built in 1665 by M. de Tracy to guard the route by way of the Richelieu to Lake Champlain and the Hudson. Population (1891), 6669; (1901), 7057.

Soria, a province of Spain, in Old Castile. Area, 3836 square miles. Population, 151,530 in 1887, 147,787 in 1897. The birth-rate is 3·84 per cent., the death-rate 3·39 per cent., and the proportion of illegitimate births 1·29 per cent., being one of the lowest in Spain. The province is divided into five districts and 345 *ayuntamientos* or parishes. Three railways run through the province. The only really important industries are connected with agriculture and the rearing of cattle. The exports are mostly timber, wool, salt, leather, and cheese. About 400,000 acres of the soil, chiefly in the mountains, are covered with forest; 1,450,000 acres are cultivated, and about 350,000 are reserved for pasture. Out of the cultivated area in 1897, 103,292 acres were covered with wheat crops, 199,135 with oats, rye, barley, maize, 13,000 with pod fruit, 12,000 with vines. The live stock in 1897 consisted of 3550 horses, 16,502 mules, 11,724 asses, 16,875 cattle, 487,109 sheep, 25,395 goats, and 14,695 pigs. There are only two salt mines and one bed of asphaltic rock actually worked in Soria.

Soria, capital of the above province, on the Douro, station at Alcuneza on the Madrid–Saragossa line. Population, 7784 in 1887, 7290 in 1897. Soria has a provincial institute, normal schools for teachers of both sexes, many primary schools, savings banks, two hospitals, barracks, a theatre, and the usual bull-ring. Near the Douro are the ruins of the old castle of Soria, and in many places the remains of the walls of the city are yet standing. The more modern streets are clean and well paved. The bridge across the Douro is a solid and massive structure, which formerly had a tower in the centre.

Soroki, a district town of South Russia, in the government of Bessarabia, 117 miles north-north-west of Kishineff and 36 miles from the nearest railway station, built in a narrow ravine on the right bank of the Dnieper. It is an important river port for the export of corn, wool, fruit, wine, and cattle, and had in 1897 a population of 15,800, half of whom were Jews. Formerly it was the old Genoese colony of Olhionia, and has still the ruins of a 13th century Genoese castle. In the 15th century the Moldavians erected here a fort, Saraki, which the Poles took in the 17th century. Peter I. conquered it in 1711, but it was returned to the Turks, and was only definitely annexed to Russia in 1812.

Sothern, Edward Askew (1826–1881), English actor, was born at Liverpool, 1st April 1826, his father being a merchant. He began acting as an amateur, and drifted into a professional engagement with a dramatic company in Jersey in 1849. Between then and 1858 he played in various capacities with no particular success in Birmingham and in America, where he went in 1852. In 1858 Tom Taylor's *Our American Cousin*, a piece of no special merit, was brought out at New York, with Sothern in the small part of Lord Dundreary, a caricature of an English nobleman. He gradually worked up the humour of this part, so that in 1861, when the play was produced at the Haymarket Theatre in London, he made such a "hit" that his impersonation was on everybody's lips, and the piece ran for nearly five hundred nights: the "Dundreary whiskers" became the fashion, and Dundreary this, that, or the other made its appearance on every side. At various times Sothern revived the character, which retained its popularity in spite of all the extravagances to which he developed its amusing features; and his name will always be famous in connexion with this rôle. In T. W. Robertson's *David Garrick* (1864) Sothern also had a great success, his acting in the title-part, which he created, being wonderfully effective, but none of his many other parts was specially remarkable. Sothern was a born comedian, and off the stage he was a notorious practical joker. He was as much of a favourite in America as in the United Kingdom. He died in London, 21st January 1881.

Sotteville, a town, arrondissement of Rouen, department of Seine Inférieure, France, one mile south of Rouen, of which it is really a suburb, continuous with Sever, on the railway from Paris to Havre. There is a chapel of the 12th and 14th centuries. Cotton-spinning and the manufacture of calicoes are conducted on an extensive scale; hemp-spinning, cordage, varnish, and gelatine represent other branches of industry. The Western Railway Company have here an extensive group of manufacturing and repairing workshops. To the south of the town is the departmental lunatic asylum of Quatre Mares, attached to that of St Yon. Population (1881), 11,738; (1901), 18,535.

Soudan. See SUDAN.

Sounding (DEEP SEA).—Wire has now entirely superseded the hemp gear formerly used for this purpose. Its smooth surface and minute section, reducing friction to a minimum, gives a rapidity of descent of about 100 fathoms per minute, and this velocity is not materially diminished even at great depths. Reeling in may be accomplished at nearly the same rate. Soundings are thus obtained with a degree of accuracy not formerly possible. The apparatus is light, compact, and automatic in its action. Soundings with wire can be carried out at night with the same facility as in daytime, and in almost any circumstances of wind and weather short of a strong gale, against which the ship could not steam or face the sea. A sounding of 1000 fathoms may be obtained in twenty-five minutes from the time the weight is lowered to the time the order is given to put the ship on her course, or in half that time if sounding from astern and going ahead on getting bottom. 2000 fathoms will require forty-five minutes, and 3000 fathoms seventy-five minutes. Beyond that depth, much greater caution being required, the time occupied is correspondingly increased, and reeling in must then be done very deliberately. The deepest sounding hitherto obtained is 5269 fathoms. Soundings at such depths may occupy as long as five or six hours.

Lucas machine.

The latest pattern of Lucas machine carries nearly 6000 fathoms of 20-gauge wire, and is fitted with two brakes, one a screw brake for holding the reel when required, the other an automatic brake for stopping the reel when the weights strike the bottom. A guider for the purpose of winding the wire uniformly on to the reel is also attached, and is worked

by a small handle. After leaving the reel, the wire passes over a registering wheel, the dial of which indicates the amount of wire run out. Similar machines of smaller size are supplied for use in boats. The large machine is represented in Fig. 1.

Heaving in is accomplished by means of a hemp "swifter" or driving belt, which conveys the motion of the drum of a donkey engine to the drum carrying the wire of the sounding machine. It being impracticable to regulate the speed of the engine by hand according to the heave of the ship, in order to obviate the sudden and excessive strains on the wire so caused an ingenious mechanical arrangement has been fitted to machines of recent pattern, by which frictional discs, geared by cog-wheels and capable of adjustment, are interposed on the axle connecting the grooved wheel actuated by the hemp swifter and the revolving drum carrying the wire. By this arrangement the latter can be controlled as desired, both in speed and direction of motion, by means of a lever regulating a strap on the frictional discs, which may be set by experiment to act at any given tension of the wire. As the tension approaches this limit, the velocity of revolution of the drum is automatically checked; and if the tension further increases, the motion of the drum is actually reversed, thus causing the wire to run out, until the tension is relieved sufficiently to allow the frictional discs again to act in the direction of heaving in. The drum may be stopped instantly by moving the lever in the proper direction to throw the apparatus out of gear.

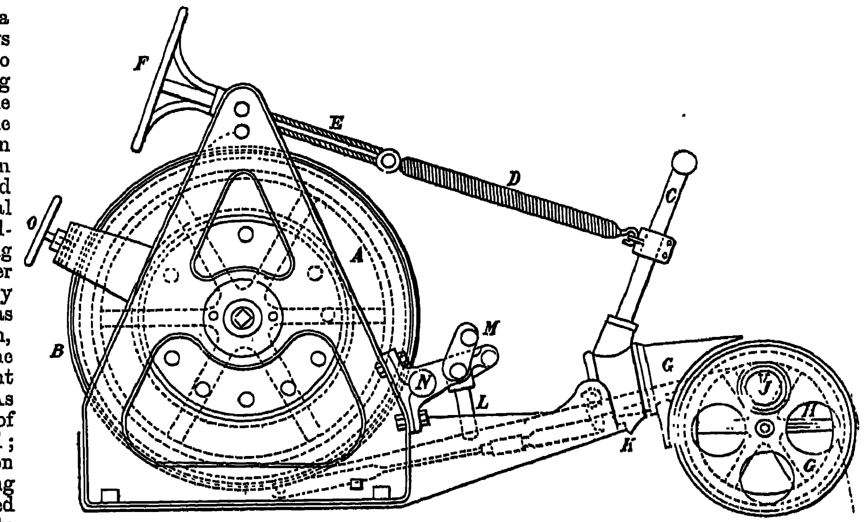

Fig. 1.—Lucas Machine (from Wharton's *Hydrographic Surveying*). A, Reel or drum; B, brake; C, brake lever; D, springs; E, regulating screw; F, hand wheel; G, swivelling frame; H, measuring wheel; J, indicator; K, stop; L, wire guiding roller; M, handle for working roller; N, bolt; O, screw brake.

Galvanized steel wire of 20-gauge and 21-gauge is supplied on drums in lengths of 5000 fathoms. The 20-gauge wire when new has a breaking strain of 240 ℔, and the smaller wire 190 ℔. The large machines now made will hold a sufficient quantity of the larger wire for the deepest soundings; there is therefore no longer any necessity for the smaller wire, and its use is not recommended. The zinc wears off to a considerable extent with constant use; it is necessary to pass the wire through an oily wad whenever soundings are suspended for a time, and the surface layers on the drum should be kept well coated with oil and covered over with oily waste. A fortnight's continuous use is about the limit to the trustworthiness of any piece of wire; no amount of care will prevent it from becoming brittle; and directly it can be snapped by twisting in the hand, it should be condemned and passed on to the boats' machines. A magnifying glass will assist in examining its condition. Taut and even winding on the reel from the drum is most important; otherwise, when heaving up after a sounding, the strain forces each layer as it comes in to sink down amongst the previous layers loosely reeled on, with the result that at the next sounding slack turns will suddenly develop on running out, to the great risk of the wire. The wire is liable to cut grooves in the interior of the swivelling frame; a file must constantly be applied to smooth them down, or they will rip the splices. A roller of hard steel, underneath which the wire passes, and placed in rear of the swivelling frame, obviates this to a great extent.

Splices are made about 5 feet in length, one wire being laid round the other in a long spiral of about one turn per inch. A seizing of fine wire is laid over each end and for two or three inches up the splice, no end being allowed to project, and solder is then applied the whole length of the splice. Three more seizings should be placed at intervals. Splices are the weakest parts of the wire, and their multiplication is to be avoided. They should be frequently examined and their position noted, so that in heaving in they may be eased round the wheel with the guider nearly in the centre, to avoid tearing.

Sounding rods and sinkers.

Under 1000 fathoms a lead of 30 to 40 ℔ weight can be recovered, and no detaching rod is necessary. At a little risk to the wire, when sounding from astern up to that depth, the ship may go ahead directly bottom is struck, increasing speed as the wire comes in; the great saving in time thus effected will often justify the increased risk of parting the wire. For greater depths the "Driver rod" is the best detaching apparatus for slipping the sinkers; its construction is easier than that of the "Baillie rod," and with a piece of gas piping cut to the proper length the ship's blacksmith can make one in a day. Both rods are fitted with tubes to bring up a specimen of the bottom, and the same sinkers fit them both.

The "Driver rod" is shown in Fig. 2. ABC is a tube about 2 feet in length, fitted at the top with a flap valve D, working on a hinge at E. The lower part of the tube C screws on and off, and contains a double flap valve to retain the bottom specimen. The sinkers WW, each 25 ℔ in weight, conical in form, and pierced with a cylindrical hole through which the Driver rod passes loosely, are slung by wire or cod line secured to a flat ring or grummet shown at L and passing over the stud G. A stud K on each side of the tube fits loosely into the slot H in the lower part of the slipping lever MH. The weight of the apparatus being taken by the sounding wire, the sinkers remain suspended; but on striking the bottom, the wire slackens, and the weight of the sinkers drags the slipping lever down till the stud K bears against the upper part of the slot H. By this action the point M of the slipping lever is brought to bear against the upper end of the standard EF, being thereby forced outwards sufficiently to ensure that the weight acting at the point G will tilt the slipping lever right over, and thus disengage the sling. The tube being then drawn up, the sinkers are left behind. In descending, the valves at top and bottom opening upwards, allow the water to pass through freely; but on drawing up they are closed, thus retaining the plug of mud with which the tube is filled. For water under 2000

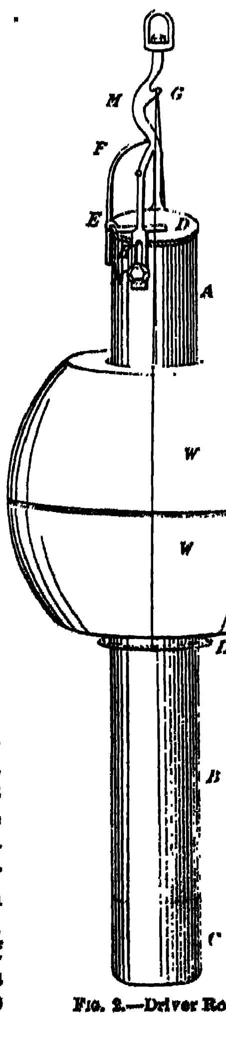

Fig. 2.—Driver Rod.

fathoms two conical weights are sufficient. In deeper water a third cylindrical weight of 20 ℔ should be put between them. It is important to interpose a piece of hemp line, some ten fathoms long, between the end of the wire (into which a thimble is seized) and the lead or rod. This tends to prevent the wire kinking on the lead striking the bottom. A piece of sheet lead about 2 ℔ in weight, wrapped round the hemp just below the junction, keeps the wire taut while the hemp slacks. Small brass screw stoppers, fitted with a hempen tail to secure to a cleat, hold the wire during the sounding if necessary to repair splices or clear slack turns. In heaving in, the springs are replaced with a spring balance, by which the amount of strain is seen and the deck engine worked accordingly. A system of signals is required by day and by night, by which the officer superintending the sounding can control the helm, main engines, and deck engine.

Method of Sounding.—The machine is placed on a projecting platform on the forecastle. An endless hemp swifter, led through blocks with large sheaves, connects the sounding machine and deck engine, and when heaving in is kept taut by a snatch block set up with a jigger. As the wire runs out, the regulating screw of the brake must be gradually screwed up, so as to increase the power of the brake in proportion to the amount of wire out. The regulating screw is marked for each 500 fathoms. In fairly smooth water the brake will at once act when the weight strikes the bottom and the reel stops. Under 3000 fathoms one spring only is sufficient, but beyond that depth two springs are required. If the ship is pitching heavily, the automatic brake must be assisted by the screw brake, to ensure the reel not overrunning. The marks on the regulating screw are only intended as a guide; the real test is that the brake is just on the balance so as to act when the strain lessens, which may be known by the swivelling frame being just lifted off the stop. As the wire weighs 7½ ℔ for each 500 fathoms, the 500-fathoms mark on the screw should be at the position in which the screw has to be to sustain a weight of 7½ ℔; the 1000-fathoms mark, 15 ℔; and so on. This can be tested, and the marks verified.

Handling the Ship.—Sounding from forward enables the ship to be handled with greater ease to keep the wire up and down, and especially so in a tide-way; but in very heavy weather soundings may be obtained from a machine mounted over the stern, when it would be quite impossible to work on the forecastle. The spanker must be set with the sheet to windward, unless a strong weather tide renders it undesirable; the ship's head must be kept in a direction which is the resultant of the direction and force of the wind and current, and this is arrived at by altering course while sounding, point by point, until the wire can be kept up and down by moving the engines slowly ahead as necessary. It should seldom, or never, be necessary to move the engines astern.

Observations of temperature. The temperature of the water is usually taken at intervals of 100 fathoms down to a depth of 1000 fathoms, and at closer intervals in the first 100 fathoms. If a second wire machine is available, the observations may be made from aft whilst the sounding is being taken forward. A 30-℔ sinker is attached to the end of the wire, and the thermometers are secured to the wire by the metal clips at the back of the cases, at the required intervals. Care must be taken to see that the indices are down before attaching the thermometers. To avoid heavy loss, not more than four thermometers should be on the wire at one time. When sounding, a thermometer is usually attached to the line a short distance above the lead.

Submarine sentry. *Submarine Sentry.*—The primary object of this machine is to supply an automatic warning of the approach of a ship to shallow water: it has been instrumental in discovering many unsuspected banks in imperfectly surveyed waters. By means of a single stout wire the sinker, an inverted kite, called the "sentry," can be towed steadily for any length of time, at any required vertical depth down to 40 fathoms with the red kite and 30 fathoms with the black kite; should it strike the bottom, through the water shallowing to less than the set depth, it will at once free itself and rise to the surface, simultaneously sounding an alarm on board, thus giving instant warning. The vertical depth at which the sentry sets itself when a given length of wire is paid out is not changed by any variation of speed between 5 and 13 knots, and is read off on the graduated dial-plate on the winch. One set of graduations on the dial indicates the amount of wire out; the other two sets refer to the red

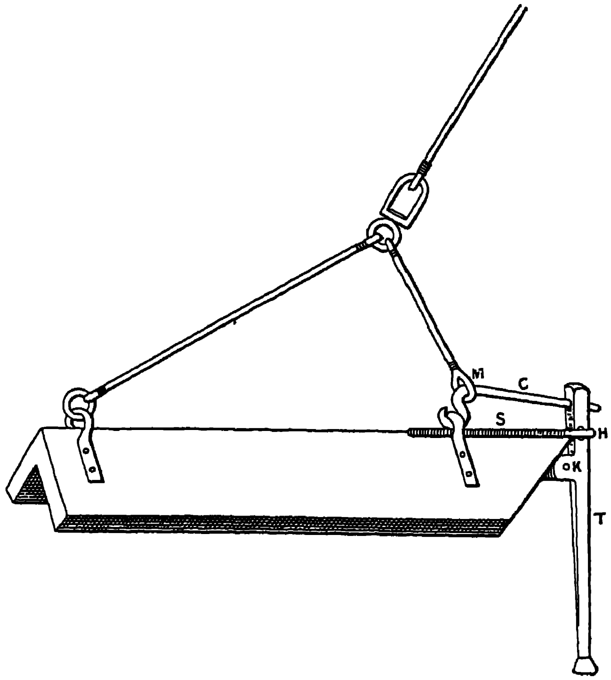

Fig. 3.—The Submarine Sentry.

and black kites respectively, and show the depth at which the sentry is towing. By this machine, single soundings down to 40 fathoms can be taken at any time while the ship is under way, the sentry being let down slowly. The gong will indicate when the bottom is touched, and the dial corresponding to the kite used will show at once the vertical depth at the place where the sentry struck.

By removing the kite and substituting a lead, with atmospheric sounder or other automatic depth gauge, flying single soundings up to 100 fathoms can be obtained in the ordinary manner without stopping the ship.

The winch is secured to the deck a short distance from the stern; the towing wire passes from the drum under a roller fairlead at the foot of the winch, thence through an iron block with sheave of large diameter, suspended from a short davit on the stern rail and secured to the sling of the sentry. The dial being set to zero with the sentry at the water's edge, the ship's speed is reduced to 8 or 9 knots, and the wire paid out freely until the kite is fairly in the water, when the brake should be applied steadily and without jerking, veering slowly until the required depth is attained, when the pawl is put on the ratchet wheel and the speed increased to 12 knots if desired when using the black kite, or 10 knots with the red kite.

The kite in its position when being towed is indicated in Fig. 3. The point of the catch C, passing through a thimble M in the short leg of the sling, is slipped into the hole at the top of trigger T, which is hinged at K and kept in its place by the spring S attached to the hook H. On the trigger striking the bottom the catch is released, the short leg of the sling slips off, and the sentry, which then rises to the surface, is left towing by the long leg. The winch is fitted with two handles for heaving in the wire; one gives great power and slow speed, and the other, acting on the drum spindle direct, winds in quickly. The wire supplied with the machine has a steady breaking strain of about 1000 ℔. Using the black kite at a speed of 7 knots, the strain on the wire is about 150 ℔, and at 10 knots about 300 ℔. The red kite increases the strain largely. (A. M. F*.)

SOUTH AFRICA.

I. Geography and Statistics.

General survey.

The expression "British South Africa"—which has obtained general currency, although it has no official sanction—came into use, or at least began to acquire a definite meaning, in the early 'eighties, when the first step towards the partition of the continent was taken by the German occupation of Namaqualand (1884). It then became at once evident that British interests could no longer be confined to the regions south of the Orange river and east of the Drakensberg range, and that the very existence of the two long-established colonies of the Cape and Natal would be imperilled unless practical measures were taken to keep open the "English road" to the interior of the continent, which had hitherto been mainly followed by missionaries, traders, and travellers. Thus arose the imperial idea of a "British South Africa," as a political domain destined in due course to embrace in one vast federation all existing colonies and all other settlements in process of development into free, self-governing states. But such a system must necessarily lack ideal completeness—such completeness as is enjoyed by the sister federations of Canada and Australia—so long as considerable tracts are held by foreign Powers on the western and eastern seaboards (German South-West Africa; Portuguese South-East Africa). In the interior, however, the unity of the system has been secured by the suppression of the late Boer states, while its borders have been enlarged by the settlement of Matabele and Mashona Lands (South Rhodesia), and by the extension of British rule, directly or indirectly, over the whole of Bechuanaland. Thus the expression British South Africa now covers the whole of the continent from the Zambezi to the Cape, the specified German and Portuguese territories alone excepted. Including these, South Africa has a total area of about 1,364,000 square miles, and a population approximately estimated (1900) at nearly 7,000,000, and is politically divided into five British colonies, two British protectorates, and two non-British colonies, with respective areas and populations as under:—

Political divisions.

Political Divisions.	Area in Square Miles.	Population (1891–1900).
Cape Colony, with Griqualand, South Bechuanaland, and Pondoland, all now incorporated . . .	277,000	1,766,000
Bechuanaland Protectorate . .	213,000	200,000
Basutoland	10,000	250,000
Natal, with Zululand and South Tongaland	50,000	1,026,000
Southern Rhodesia (Matabele and Mashona Lands) . . .	175,000	450,000
Orange River Colony . . .	48,000	207,000
Transvaal Colony	119,000	1,094,000
German South-West Africa . .	322,000	200,000
Portuguese territory south of the Zambezi (Delagoa Bay, &c.) .	150,000	1,750,000
Total . .	1,364,000	6,943,000

Physical features.

Africa south of the Zambezi forms a vast tableland which stands at a mean elevation of about 4000 feet above sea-level, and is buttressed seawards by a great mountain system disposed in concentric ranges roughly parallel with the contour lines of the continent, at distances of from 100 to 250 miles from the coast. The inner encircling range, which falls through secondary parallel chains, or through steeply scarped terraces, the so-called karoos, down to the seaboard, is continuous only on the south and east sides facing the Austral and Indian Oceans, and on the west as far north as the Oliphant river. Beyond this point the system loses the aspect of an unbroken rampart, the outer scarps have been greatly eroded, the coast ranges become more fragmentary, and at last entirely disappear at the broad estuary of the Orange river. Still farther north little is to be seen except low, rocky hills and ridges, almost lost amid the shifting dunes of the sandy Namaqualand plains. But in the direction of the east and north-east the rise is continuous through the Roggeveld, the Nieuwveld, the Sneeuwberg, and the Stormberg round to the Quathlamba (Drakensberg) range, where the whole system culminates in peaks from 10,000 to nearly 11,000 feet high at the converging frontiers of Basutoland, Natal, and the Orange River Colony. From these Alpine heights the Drakensberg is continued at a mean altitude of 8000 feet along the Natal frontier right into the Transvaal, broken only by a few difficult passes, such as Tintwa, Van Reenens, Botha's, and Lang's Nek at Majuba Hill. Beyond Natal the escarpments of the plateau again fall to 5000 or 6000 feet and assume a more broken character along the Transvaal frontier, where they have been subject to much weathering and erosion, presenting in places the appearance of marine headlands, whence the term *Kaap*, "Cape," applied to the cliffs in this auriferous district. Here the Randberg ("Border range"), as it is called, is flanked seawards by the less elevated Lobombo Coast range; and beyond the Mauchberg, culminating point of the Transvaal (8725 feet), the whole system gradually merges in a broad expanse of moderately elevated uplands, intersected transversely to the main range by the Zoutpansberg and Murchison Rand, between the Oliphant and Limpopo rivers. North of the Limpopo the eastern escarpments again assume a mountainous aspect between Portuguese territory and Southern Rhodesia, broadening out northwards in the Mashona highland, and developing in Matabeleland the historical Matoppo ridge, which forms the true water-parting between the Limpopo and the Zambezi rivers.

From the inner slopes of the encircling ranges, thus roughly outlined, the great continental plateau stretches away for interminable distances through the former Boer states and Bechuanaland from the Orange northwards to the Zambezi, and through the Kalahari desert westwards to the Atlantic Ocean. It has a total area of not less than 900,000 square miles; and the tilt of the land being westwards in the south and eastwards in the north, the drainage is almost entirely through the Orange to the Atlantic, and through the Limpopo, Sabi, Bosi, Pungwe, and Zambezi to the Indian Ocean. Lying between the low latitudes of 16° and 35° S., while also exposed to the moist monsoons and warm marine currents of the Indian Ocean, South Africa should be distinguished by a hot, wet, tropical or subtropical climate. But these conditions are fully realized only on the eastern seaboard between the Zambezi and the Cape, and are elsewhere profoundly modified by the great mean elevation of the land (4000 feet), by the cold marine and aërial currents setting from the Antarctic waters along the west coast, and by the great altitude of the eastern escarpments (Drakensberg, Randberg), by which, as in Australia, the rain-bearing oceanic trade winds are intercepted, leaving but a slight precipitation for the central and western regions. Hence in the direction of the east the

Climate.

increase of the rainfall is continuous, rising from 3 or 4 inches in Namaqualand and 8 to 16 in Bechuanaland to 24 at Pretoria and Bloemfontein, and 40 or even 50 in Natal. The temperature is much more uniform, the mean for the whole year lying almost everywhere between 60° and 70° F., while the mean of the extremes ranges from 40° to 91° at the Cape, 32° to 95° at Pietermaritzburg, 40° to 105° at Kimberley and Pretoria, 41° to 94° at Bloemfontein, and 40° to 106° at Bulawayo. But owing to the dryness of the atmosphere, this intense heat is far less oppressive than might be supposed, and many parts not only of the Cape but of the central plateau and the Rhodesian uplands are perfectly salubrious and well adapted to the European constitution. The prevailing complaints—enteric fever, ague, diarrhœa, and dysentery—are due either to the bad water or to long exposure and hardships, or else are confined to the low-lying swampy and riverside tracts. Elsewhere fever is almost unknown, while the Matabele and Mashona uplands, where white families are already established, are declared to be even more healthy than Natal and other parts of the long-settled seaboard. The generally salubrious nature of the climate is indeed placed beyond doubt by the persistence of the Boer race and of the English settlers, all noted for their longevity, robust physique, and vigorous offspring.

Flora and fauna.

On the plateau the deficient moisture is everywhere reflected in the poverty and general character of the vegetation, marked by the absence of woodlands and the great predominance of thorny scrub and herbaceous growths. Prickly acacias, euphorbias, and mimosas are characteristic of the high veld, where the eye sweeps over vast grassy plains or rolling steppes, and lights on nothing but a few clumps of low, shadeless trees, marking the sites of the Boer farmsteads dotted thinly over the steppe. The native grasses yield rich pasturage during the wet summer months, but mostly disappear in the dry winter season, and then the only visible vegetation is the so-called "bush," that is, the acacias, willows, mimosas, yellow-wood, iron-wood, and wild fig, by which the watercourses are often densely fringed. On the other hand, the soil is naturally rich, and where water is available some districts yield two annual crops of cereals, especially mealies (maize) and some of the finest wheat in the world. Tobacco, the vine, and most European fruits and vegetables thrive well, while sugar, coffee, cotton, and other colonial produce already grown in Natal might also be successfully cultivated in the Limpopo valley. But so far only a mere fraction of the available land has been brought under tillage; and although its agricultural resources are boundless, no great progress can be expected until some practical steps are taken to get rid of the locust pest and introduce the urgently-needed irrigation works in a large way. Meanwhile the boundless pastures support multitudes of horned cattle, horses, goats, merinos, and fat-tailed sheep. These more profitable domestic animals have to a large extent crowded out the beasts of prey and the game of all kinds which till recently abounded in prodigious multitudes. Formerly such characteristic members of the African fauna as the lion, leopard, hyæna, elephant, buffalo, zebra, quagga, giraffe, baboon, rhinoceros, gnu, eland, springbok, gazelle, and other antelopes in endless variety swarmed over the inland plateaux and the surrounding slopes, while the large streams were infested with the crocodile and hippopotamus. The early travellers speak of the hartebeest, gnu, and springbok scouring the plains and migrating in herds of ten or even fifteen thousand from pasture to pasture between the Cape and the then unknown northern wilderness beyond the mountains. But they are now seldom seen even in the wilderness itself, and to prevent their total extinction some species are sheltered in public or private preserves in the Cape and the Transvaal. The lion is said to have ceased to roar, though still lingering about the haunts of men; the quagga and white rhinoceros seem to have died out, and the hippopotamus has disappeared from most of the rivers.

Inhabitants.

The same fate has overtaken nearly all the Vaalpens, Bushmen, and Hottentots, who represent the true aboriginal element south of the Zambezi, and are described in separate articles. All the other natives, popularly called "Kaffres," are members of the widespread Bantu family (see BANTUS), of whom they here form three distinct branches: 1. The *Zulu-Xosas*, originally confined to the south-east seaboard between Delagoa Bay and the Great Fish river, but later (19th century) spread by conquest over Gazaland, parts of Transvaal, and Rhodesia (Matabeleland). 2. The *Bechuanas*, with the kindred *Basutos*, on the continental plateau from the Orange to the Zambezi, and ranging eastwards into the late Boer states and Basutoland, and westwards over the Kalahari desert and the Lake Ngami region. 3. The *Ova-Herero* and *Ova-Mpo*, confined to German South-West Africa between Walfish Bay and the Cunene river. All these mixed Bantu peoples, who all speak dialects of the extinct Bantu stock language, are immigrants at various periods from beyond the Zambezi. The Bechuanas, who still occupy by far the largest domain, and alone preserve the totemic tribal system in its integrity, were probably the first arrivals from the north or the north-east coastlands. There is reason to believe that they formed the bulk of the native populations when Austral Africa was reached, some two or three thousand years ago, by the ancient navigators who came hither, most probably from South Arabia, in quest of gold, and to whom the late Theodore Bent has rightly attributed the remarkable Zimbabwe monuments still extant near Victoria, in Southern Rhodesia (Matabeleland). These remains, with their lofty round tower, encircling walls and ramparts, all in well-dressed stone, display remarkable constructive skill, far beyond the power of any of the present or past rude inhabitants of the land. They comprise well-planned fortifications for the defence of the prehistoric gold mines, and temples with numerous carvings, emblems, and detached objects, which plainly point to ancient Semitic religious rites. No inscriptions have yet been discovered, but in the Malagasy language of the neighbouring island of Madagascar distinct elements still survive of the old Himyaritic speech which was current in South Arabia under the Sabæan and Minæan empires, and is not yet quite extinct. The inference seems therefore reasonable that the Zimbabwe monuments are the work of the ancient civilized inhabitants of South Arabia, perhaps co-operating with their Phœnician kindred, who were ever exploring the eastern seas in search of the gold and other treasures reported from the "land of Ophir."

The Zimbabwe ruins.

Gold and diamonds.

Gold, with diamonds of recent discovery, still constitutes the chief mineral wealth of South Africa, which in both of these respects may be regarded as unrivalled. Full details are given elsewhere (CAPE COLONY, TRANSVAAL), and here it will suffice to state that while the Kimberley output controls the diamond markets of the world, in 1898 the Transvaal gold harvest exceeded that of Australia, Siberia, and America. The diamantiferous blue clays ("pipes") are not confined to the Cape, and rich auriferous reefs range far beyond Transvaal into Southern Rhodesia. In other respects South Africa is well mineralized, and besides iron, copper, tin, and silver, extensive coal-fields occur in the Cape (Molteno district), in Natal and Zululand (Newcastle, Nougoma), in the Orange River Colony (Kroonstad), and in various parts of

the Transvaal and Rhodesia nearly up to the banks of the Zambezi.

Economic condition.

In the following table are brought together a few leading data showing the economic condition (1898–1900) of the various British South African colonies for which accurate returns are available :—

	Cape.	Natal.	Orange River.	Transvaal.	Basuto-land.
Imports	£19,207,000	£5,359,000	£1,191,000	£13,500,000	£85,500
Exports	23,660,000	1,325,000	1,924,000	..	134,000
Revenue	8,781,000	2,081,000	800,000	3,983,000	70,500
Expenditure . . .	8,190,000	1,915,000	957,000	3,971,000	60,000
Debt	31,410,000	9,019,000	30,000	2,660,000	..
Cattle	1,076,000	278,000	896,000	*Gold.*	321,000
Horses . . .	388,000	57,000	249,000	1890.	81,000
Sheep	1,264,000	600,000	6,620,000	£1,870,000	
Goats	5,573,000	450,000	858,000	1893.	
Wool crop . . .	37,180,000 lb.	*Tea.*		3,480,000	
Mohair	6,707,000 ,,	1,037,000 lb.		1895.	
Wheat	2,221,000 bush.	*Coal.*		8,570,000	
Mealies	2,858,000 ,,	388,000 tons		1898	
Oats	1,810,000 ,,	*Bark.*		16,044,000	
Ostrich feathers . .	278,000 lb.	£58,000		1884–98.	
Wine	4,826,000 gals.	*Sugar.*		69,845,000	
Brandy	1,107,000 ,,	£147,000		*Coal.*	
				1,908,000 tons	
Diamonds	£4,135,000	..	£1,508,000	£43,700	..
Railways	2300 miles	591 miles	392 miles	774 miles	..
White population . .	390,000	48,000	78,000	150,000	600
Coloured population .	1,400,000	513,000	130,000	712,000	25,000

From this table it appears that about 4000 miles of railways had been opened by 1900. In that year about 1000 additional miles were either in progress or projected; and when these are finished, the interior will enjoy the advantage of railway access to the coast and to the Zambezi at eight different points—Walfish Bay, Cape Town, Port Elizabeth, East London, Durban, Delagoa Bay, Beira, and some place on the Zambezi below the Victoria Falls. The main line from Cape Town northwards has already reached Bulawayo, a distance of 1360 miles; and this is now regarded as merely the southern section of a transcontinental "Cape-to-Cairo" line, which it is proposed to construct mainly through British territory, the northern section of which is also completed from the Mediterranean to Khartum, a distance of 1350 miles. As the total distance is 6610 miles, there is still left a central section of 3900 miles to complete the system by the route originally proposed. But recent exploration about the White Nile headwaters shows that considerable deflections may have to be made, to avoid the almost impassable swampy tracts north of the equatorial lakes; and there are other difficulties, which render the expectations of those who hope to see the undertaking out of hand within the first decade of the 20th century a little sanguine. But whenever the railway is completed, the results must be far-reaching, and must tend enormously to develop the material resources of British South Africa.

Railways: the Cape-to-Cairo scheme.

(A. H. K.)

II. MODERN HISTORY.

For historical purposes South Africa may be taken to include that part of the African continent which lies to the south of the Congo State on the west and German East Africa on the east. Within it are situated Portuguese East and West Africa, Rhodesia, German South-West Africa, Cape Colony, Natal, Basutoland, Orange River Colony, and Transvaal. The European colonization of these territories has occurred step by step, the establishment of one colony or state leading on to the establishment of another. As it is through the European colonists that we have obtained such information as we possess with regard to the native races of the country, it will be most convenient to deal with colonization first in the order of its occurrence, and to consider the native races afterwards. The relations of the white and aboriginal races in the various colonies will also be dealt with.

European colonization.

What led to the discovery of America led also to the discovery, exploitation, and colonization of South Africa. In the 15th century the great Eastern trade with Europe was carried on by the Venetian Republic—Venice was the gate from West to East, and her fleets, richly laden with goods brought down to the shores of the Mediterranean in caravans, supplied Europe with the luxuries of the Orient. It was in that century that Portugal rose to prominence as a maritime power; and being anxious to enjoy at first hand some of the commerce which had brought such prosperity to Venice, Portugal determined to seek out an ocean pathway to the Indies. It was with this intention that Columbus sailed westward and discovered America, and that Bartholomew Diaz, sailing southwards, discovered the Cape of Good Hope. The story of these early voyages is full of gallant adventure, hardihood, and romance. It is sufficient here to record that in 1486 Diaz, having rounded the Cape, entered Algoa Bay, and landing upon a small island, erected a cross as a token that he had taken possession of the country for the king of Portugal. Returning, he sighted the Cape in heavy weather, and christened it the Cape of Storms. This name was subsequently changed by the Portuguese king into that of the Cape of Good Hope. In 1500, while on another voyage to the Indies, the brave Portuguese explorer Diaz went down with his ship in the Atlantic. Eleven years after the first expedition of Diaz another Portuguese expedition was fitted out under Vasco de Gama. De Gama entered Table Bay, but did not land. From here he pushed on round the coast, landed in Mossel Bay, then sailing up the south-east coast, he sighted land again on 25th December 1497, and named it in honour of the day, Natal. Still proceeding northwards, he fell in with coast pilots, and eventually reached the coast of Malabar, in the island of Java.

The Portuguese.

For a hundred years subsequent to this date Africa represented merely an inconvenient promontory to be rounded on the voyage to the Indies. Ships stopped at different ports, or rather at such few natural harbours as the inhospitable coast offered, from time to time, but no attempt was made by the Portuguese to colonize the southern end of the continent. They did, however, in course of time establish ports, and through them small settlements, on the eastern and western sides of South Africa, and these to-day are represented by Portuguese East and West Africa.

English East India Company.

The first Europeans to follow in the wake of the Portuguese Indian voyagers were the English. In 1601 the English East India Company fitted out a small fleet of five vessels, which sailed from Torbay. After four months at sea they dropped their anchors in Table Bay, where they landed and remained for seven weeks before proceeding eastwards. From that time forward Table Bay was used as an occasional port of call for British ships, and in 1620 two English captains formally took possession of the Cape in the name of James I. This patriotic act

was not, however, sufficiently appreciated by either King James I. or the English East India Company to evoke any official confirmation on their part. Meanwhile the Dutch East India Company had been formed in Holland, and the Dutch had entered keenly into the competition for the glittering prizes of Eastern commerce. In 1648 one of their ships was stranded in Table Bay, and the shipwrecked crew were left to forage for themselves on shore for several months. They were so pleased with the resources of the country that on their return to Holland they represented to the directors of the company the great advantages that would accrue to the Dutch Eastern trade from a properly provided and fortified station of call at the Cape. The result was that in 1652 a fort and vegetable gardens were laid out at Table Bay by a Dutch expedition sent for the purpose under a surgeon named van Riebeek.

Dutch East India Company.

In 1657 a few soldiers and sailors, discharged by the Dutch East India Company, had farms allotted them, and these men constituted the first so-called "free burghers." By this step the station became a plantation or settlement. More settlers were landed from time to time from the passing Dutch ships, and in 1688 180 French Huguenots were added to the original settlers. The little settlement grew slowly, but gradually spread eastwards until in 1778 the Great Fish river was declared the boundary of the Cape of Good Hope. All through the latter half of the 17th, and the whole of the 18th, century troubles arose from time to time between the colonists and the Government. The administration of the Dutch East India Company was of an extremely despotic character. The most interesting and complete account of the company's tenure and government of the Cape was written in 1857 by Mr E. B. Watermeyer, a Cape colonist of Dutch descent residing in Cape Town. He points out that it was after failing to find a route by the north-east to China and Japan that the Dutch turned their eyes to the Cape route. The Cape of Good Hope subsequently "became not a colony of the Republic of the United Provinces, but a dependency of the 'Netherlands Chartered General East India Company' for mercantile purposes; and to this fact principally can be traced the slow progress, in all but extension of territory, of a country which was settled by Europeans within thirty years of the time when the Pilgrim Fathers, the founders of a mighty empire, landed at Plymouth to plant democratic institutions and European civilization in the West."

On the settlement under van Riebeek, and the position in it which the so-called "free burghers" enjoyed, this candid Dutch writer, whose lectures are now out of print, throws an interesting light.

"The people," he says, "who came here with Riebeek himself were not colonists intending permanently to settle at the Cape. All were paid servants of the company: the men, in course of time, to be removed to other stations; the officers, especially the commandant, who, after the first year, urgently pressed his claim for promotion, expecting to be transferred to more lucrative posts in India. A watering and cattle station of the company, under the charge of the servants of the company, was all that was intended by the occupation of 1652. The proposition that any freemen or burghers, not in the pay of the company, should be encouraged to cultivate the ground was first made about three years after Riebeek's arrival. Accordingly, some discharged sailors and soldiers, who received, on certain conditions, plots of ground, extending from the Fresh River to the Liesbeek, were the first free burghers of the colony. . . . Here it is sufficient to say that, generally, the term 'free burgher' was a complete misnomer. The first burghers were, in truth, a mere change from paid to unpaid servants of the company. They thought, in obtaining their discharge, that they had much improved their condition, but they soon discovered the reverse to be the fact. And henceforward to the end of the last century, we find the constantly repeated and well-founded complaint, that the company and its officers possessed every advantage, while the freemen were not allowed even the fruit of their own toil. Traffic with the natives, at first permitted on stringent conditions, was soon prohibited, lest thereby prices should become too high for the company when inclined to purchase. The 'free burghers' might buy nothing except from the company, at the company's store and price. They were prohibited, according to the caprice of the governors, from fishing in the bays. They might not supply strange ships, for strangers were to be discouraged. Twenty years after the establishment of the settlement, Commissioner Verburg examined into the state of the colony for the information of the home authorities, and thus reports:—'The Dutch colonists at the Cape of Good Hope bear the name of freemen; but they are so trammelled and confined in all things that the absence of any freedom is but too manifest. The orders and proclamations from time to time issued are so rigid that it would be impossible to carry out the penalties therein, except with the utter ruin of the burghers.' The natural effect of this narrow and tyrannous rule was discontent, amounting often to disaffection. After a time every endeavour was made to escape beyond the immediate control of the authorities. Thus the 'trekking' system, with its attendant evils, the bane of South Africa, was born. By their illiberal spirit, which sought but temporary commercial advantage in connexion with the Eastern trade, the Dutch authorities themselves, although generally humanely disposed towards the natives, created the system which caused their oppression and extermination."

When it is borne in mind that the Dutch at the Cape were for one hundred and forty-three years under the rule of the Dutch East India Company, *i.e.*, for considerably more than half the period of their entire residence in that country, the importance of a correct appreciation of the nature of that rule to any student of South African history is obvious. No modern writer — not even the South African historian Dr Theal—approaches Watermeyer either in the completeness of his facts or the severity of his indictment. Referring to the policy of the company, Watermeyer says:—

"The Dutch colonial system as exemplified at the Cape of Good Hope, or rather the system of the Dutch East India Company (for the nation should not wholly suffer under the condemnation justly incurred by a trading association that sought only pecuniary profit), was almost without one redeeming feature, and was a dishonour to the Netherlands' national name. In all things political, it was purely despotic; in all things commercial, it was purely monopolist. The Dutch East India Company cared nought for the progress of the colony—provided only that they had a refreshment station for their richly laden fleets, and that the English, French, Danes, and Portuguese had not. Whatever tended to infringe in the slightest degree on their darling monopoly was visited with the severest penalties, whether the culprit chanced to be high in rank or low. An instance of this, ludicrous while grossly tyrannical, is preserved in the records. Commander van Quælbergen, the third of the Dutch governors of the colony, was dismissed from the government in 1667, and expelled the service of the company, because he had interchanged civilities with a French governor bound eastwards, the United Provinces being then at peace with France. 'Not only,' so the despatch appointing Quælbergen's successor complained, 'had he ventured to give the French a kindly reception ashore, but he had quitted his post in the fort, and had proceeded on board of the French ship, a most inexcusable fault, for which the Chamber of XVII. felt bound to express their grievous displeasure, as subversive of all military discipline.'

"Of this nature was the foreign policy of the Dutch company at the Cape of Good Hope; modified, indeed, in some degree from time to time, but governed by principles of jealous, stringent monopoly until the surrender of the colony by Commissioner Sluysken in 1795. The internal government of the colonists for the entire duration of the East India Company's rule was always tyrannical, often oppressive in the extreme. With proclamations, placaats, and statutes abundantly filling huge tomes, the caprice of the governor was in truth the law. The excesses and enormities of van der Stell at a comparatively early period of our history, of van Plettenberg and a despotic functionary, the 'Independent Fiscal' Boers, towards the close of the last century, and of many intervening petty tyrants, are in truth almost incredible to us, who, called freemen, enjoy the rights of freemen, and who would fain believe that those who bore this name in our country in the olden time were privileged, as we are, to know the blessings of liberty. A mockery of popular institutions, under the name of a Burgher Council, indeed existed; but this was a mere delusion, and must not be confounded with the system of local government by means

of district Burgher Councils which that most able man, Commissioner de Mist, sought to establish during the brief government of the Batavian Republic from 1803 to 1806, when the Dutch nation, convinced and ashamed of the false policy by which they had permitted a mere money-making association to disgrace the Batavian name, and to entail degradation on what might have been a free and prosperous colony, sought to redeem their error by making this country a national colonial possession, instead of a slavish property, to be neglected, oppressed, or ruined, as the caprice or avarice of its merchant owners might dictate."

From time to time servants in the direct employment of the company were endowed with the right of "free burghers." One of the documents conferring this privilege was brought to light by the researches of Watermeyer. It is a quaint instrument, and will illustrate better than anything else can the attitude of the Government to the colonists:—

"Joachim van Plettenberg, Governor of the Cape of Good Hope and its dependencies, greeting; Whereas Johan Hendrik Gans, of Lippolsberg, who arrived here in the year 1770 with the ship *Veldhoen*, as soldier at the pay of nine guilders per month, hath by petition particularly requested of us to be discharged from the service of the Honourable Company and to be appointed (aangesteld) as burgher, having duly served the Honourable Company.

"Wherefore, we graciously grant his request to earn his livelihood here, or elsewhere within the colony, with his handicraft as a tailor; but that he shall not be allowed to abandon the same, or to adopt any other mode of living, unless he shall first have obtained special permission thereto from this Council, and that he shall not petition for any grant of land from the Honourable Company, which specially reserves the right and power, at any time when it may be deemed necessary, or whenever his conduct shall not be proper, to take him back into service in his old capacity and pay, and to transport him hence, if thought fit; further submitting him to all such placaats as have already, or may in future be enacted regarding freemen.

"Done at the Castle of Good Hope, 5th September 1780.

"J. VAN PLETTENBERG.

"O. M. BERGH, *Secretary*."

"This right to enforce into servitude those who might incur the displeasure of the governor or other high officers was not only exercised with reference to the individuals themselves who had received this conditional freedom: it was claimed by the Government to be applicable likewise to the children of all such."

The Trek Boers. The effect of this tyranny was inevitable: it drove men to desperation. They fled from oppression; and thus trekking began, not in 1837, as is generally stated, but before the commencement of 1700. From 1720 to 1780 trekking had gone steadily forwards. In 1780 van Plettenberg, the governor, proclaimed the Sneeuwbergen the boundary of the colony, expressing "the anxious hope that no more extension should take place, and with heavy penalties forbidding the rambling peasants to wander beyond." In 1789 so strong had feeling amongst the burghers become that delegates were sent from the Cape to interview the authorities at Amsterdam. After this deputation some nominal reforms were granted; but in 1795, after a further period of disaffection at the Cape, a number of burghers settled in the Swellendam and Graaff Reinet districts drove out the officials of the company and established independent governments. This rebellion was accompanied by an assertion of rights on the part of the burghers or freemen, and this same declaration contained the following clause, from the spirit of which the Trek Boers never really departed:—

"That every Bushman or Hottentot, male or female, whether made prisoner by commanders or caught by individuals, as well in time past as in future, shall for life be the lawful property of such burghers as may possess them, and serve in bondage from generation to generation. And if such Hottentots should escape, the owner shall be entitled to follow them up and to punish them, according to their merits in his discretion.

"And as to the ordinary Hottentots, already in service, brought up at the places of Christians, the children of these shall be compelled to serve until their twenty-fifth year, and may not go into the service of any other save with their master's consent; that no Hottentot, in future, deserting his service shall be entitled to refuge or protection in any part of the colony, but that the authorities throughout the country shall immediately, whatever be the alleged cause of desertion, send back the fugitive to his master."

After one hundred and forty-three years the rule of the Dutch East India Company came to an end at the Cape. What its principles were we have already seen. Watermeyer recapitulates its effects as follows:—

"The effects of this pseudo-colonization were that the Dutch, as a commercial nation, destroyed commerce. The most industrious race of Europe, they repressed industry. One of the freest states in the world, they encouraged a despotic misrule in which falsely-called free citizens were enslaved. These men, in their turn, became tyrants. Utter anarchy was the result. Some national feeling may have lingered; but, substantially, every man in the country, of every hue, was benefited when the incubus of the tyranny of the Dutch East India Company was removed. Since then the advancement of the colony, both under an English and a brief Dutch administration (1803 to 1806), has been as rapid as that of any in the world. So great has been the progress, so utterly different is the condition of the inhabitants, so much has in the intermediate sixty years been effected, that it is with incredulity, and with some effort, that we are compelled to accept the fact that affairs within so short a period were in the state which our history describes."

To this one further note must be added. The Trek Boers of the 19th century were the lineal descendants of the Trek Boers of the 18th. What they had learnt of government from the Dutch East India Company they carried into the wilderness with them. The end of the 19th century saw a revival of this same tyrannical monopolist policy in the Transvaal. If Watermeyer's formula, "In all things political, purely despotic; in all things commercial, purely monopolist," was true of the government of the Dutch East India Company in the 18th century, it was equally true of Mr Kruger's government in the latter part of the 19th.

The British at the Cape. In 1806, as one of the results of war, France and Holland being united against Great Britain, the Cape was seized by a British force. In 1814, at the close of the war with Holland, Great Britain surrendered to her all colonies seized during the war, with the exception of the Cape and portions of what are now British Guiana. In consideration of retaining these territories Great Britain paid to Holland £6,000,000. The British title to Cape Colony is thus based upon conquest, treaty, and purchase. The population at that time was estimated at 26,700 Europeans, 17,650 free Hottentots, and 29,000 slaves. We have now dealt with the introduction of Portuguese, Dutch, and British to South Africa. Germany did not enter upon the scene until 1883, when the German flag was hoisted in Damaraland, on the south-west coast.

The native races. Before tracing the development and history of the country during the 19th century, and endeavouring to estimate the part that the European races have played, it is necessary to consider the native races of South Africa. The natives first encountered by the early voyagers and the Dutch settlers at the Cape were the Hottentots. They at this time occupied the Cape peninsula and surrounding country, and in the early days of the settlement caused the colonists a considerable amount of trouble. An extract from the diary of van Riebeek in 1659 will best illustrate the nature of the relations existing between colonists and natives at that time:—

"*3rd June.*—Wet weather as before, to the prevention of our operations. Our people who are out against the plundering Hottentots, can effect nothing, neither can they effect anything against us; thus during the whole week they have been vainly trying to get at our cattle, and we have been trying vainly to get at their persons; but we will hope that we may once fall in

with them in fine weather, and that the Lord God will be with us."

The Hottentots, like the other negroid races of Africa, lived in clans or tribes and occupied kraals or villages. They tilled the soil to a limited extent, and possessed flocks and herds. A study of their ethnology, language, &c., will be found under HOTTENTOTS (see also under AFRICA: *Ethnology*). Throughout Cape Colony to-day the Hottentots chiefly reside as servants on farms, although in Namaqualand the Namaquas and Korannas are both Hottentot tribes, and still live in a state of semi-tribal independence. The Bushmen resemble the Hottentots to some extent in appearance. They are a race of pigmies (see BUSHMEN). Between the Bushmen and Hottentots in the early days an inveterate hostility usually existed. Yet occasionally a party of Bushmen would be attached as hunters and scouts to a Hottentot tribe. For the most part, however, both among black and white races, the Bushmen's hand has been against every man and every man's hand against him. To-day the Bushmen have almost disappeared from Cape Colony, though the abundant evidence of their deserted caves and old habitations attest that they once resided there in considerable numbers. When first known to the early colonists, they were inveterate stock thieves, and were treated by the Boers as wild animals, to be shot whenever an opportunity occurred. The habitat of these pigmy races is a wide one, and extends from the Libyan deserts of Herodotus through the regions of Central Africa to the Cape. To-day such Bushmen as are left in South Africa are to be found chiefly in the deserts of the south-west. Such opposition as Hottentots and Bushmen were able to offer to colonization was not difficult to overcome. The feuds of the early days with the Hottentots soon came to an end, and the Bushmen, who lived in small communities, were hunted like wild game. The formidable native power of the great Bantu tribes was not encountered until later in the 18th century, when the boundary of the colony was extended to the Fish river (see BANTU). The first of the Kaffre wars, of which a long series occurred in the 19th century, was in 1811, when the Kaffres crossed the Fish river and occupied neutral territory to the south of it. The Bantu, like the Europeans, were invaders of South Africa, and while the European tide of immigration flowed in from the south, the Bantu came in successive migrations from the north down the east coast of South Africa. The meeting of these rival invaders on the Kaffre frontier was the scene of many bloody conflicts. In 1819 the Kaffres again crossed the Fish river, and, headed by Mahana, a prophet, they penetrated through the dense bush country lying to the south of the Fish river, and attacked in large numbers the fort and settlement at Grahamstown, which was defended by only 320 men. The Kaffres were finally driven off; but this last invasion convinced Lord Charles Somerset, then governor of the colony, of the necessity for a line of frontier forts and a more numerous settlement of colonists. Representations on the matter in England, coupled with assurances from Somerset as to the fertility of the district, induced the British Government to vote £50,000 for the purpose of sending out a number of emigrants. Applications were called for, and no less than 90,000 were received. Of these, only 4000 were selected and shipped to South Africa. They were landed in 1820, in Algoa Bay, where they founded Port Elizabeth and the Albany settlement. Among these settlers were a number of married men with families. They were recruited from England, Ireland, and Scotland, and came from all grades of society. Among them were cadets of old families, retired officers, professional men, farmers, tradesmen, mechanics, and labourers. They encountered many difficulties and some suffering in their early days, but on the whole they throve and prospered. Their descendants, the Atherstones, Bowkers, Barbers, Woods, Whites, Turveys, and a number of other well-known frontier families, are to-day the backbone of the eastern province, and furnish the largest portion of the progressive element in Cape Colony. Among them was a gifted Scotsman named Thomas Pringle. His poem entitled "Afar in the desert I love to ride" and other poems have depicted the scenes of those early days in glowing and eloquent lines. The vast spaces of the veld, the silence of the solitudes, the marvellous varied and abundant animal life, the savage half-weird character of the natives, and the wild adventure of the early colonists have been caught with a true spirit of genius. Since his day no one, unless it be Olive Schreiner in *The Story of an African Farm*, has so vividly painted the life and the atmosphere of that vast continent lying to the south of the Zambezi. Pringle did more than write poetry: he opposed the somewhat despotic rule of Lord Charles Somerset, and gallantly stood up for the causes of liberty of the press and education in the colony. In 1826 he returned to England and threw himself into the anti-slavery agitation. He became secretary of the Society for the Abolition of Slavery, and heartily co-operated in the great work it had undertaken. He was the author of the lines, at one time famous—

British settlers of 1820.

> "Oppression, I have seen thee face to face,
> And met thy cruel eye and clouded brow."

Emancipation of slaves.

In 1834 occurred another terrible Kaffre invasion. Many Europeans were massacred, farmhouses burnt, and an enormous quantity of stock taken from the colonists, before the Kaffres were eventually driven back across the Keiskamma river. In the same year the Slave Emancipation Act, emancipating all slaves throughout the British Empire, came into force. The slaves in Cape Colony, who consisted chiefly of imported negroes from the West Coast of Africa and of Hottentots, were estimated at the time at 36,000. These slaves were valued at the Cape at £2,000,000. The sum actually voted by the British Government to slave-owners in Cape Colony, out of a total compensation paid of £20,000,000, was £1,250,000. This money was unfortunately only made payable in London, and the farmers were compelled to sell their claims for compensation to agents, who frequently paid a merely nominal price for them. In many instances farmers found themselves quite unable to obtain native labour for a considerable time subsequent to the emancipation, and in some cases, no doubt, ruin was the result. The feeling created among the Dutch colonists was very bitter. Many of the farmers, who had parted with their claims to compensation for a trifling sum, found themselves without labour or means of paying for it. At the same time, of the soundness of the general principle of the Act of Emancipation there cannot be a shadow of question.

Quite apart from the actual tyranny exercised over the natives, from which they suffered heavily, there was a still more disastrous result of slavery in South Africa. The ownership of native women led to a numerous bastard offspring, some of whom were in due course themselves sold as slaves. The influence upon the owners of such a practice as this was degrading to a degree. The intimate contact, lasting now for two centuries, between the Dutch and the natives, has exercised a marked influence upon Boer character. The liberation

of the slaves doubtless diminished the evil effect of this influence, but among the Boers of the Transvaal a system of apprenticeship hardly less rigid than slavery has existed down to the present day. In justice to the Dutch, it is only fair to say that the question of the relationship between white master and black servant has always been a difficult one. The difficulties were greatly enhanced where master and servants lived on distant farms, two or three days' journey from a magistrate or field cornet. A system of punishment applicable on the spot was a necessity, and summary justice was often administered long after slavery ceased to exist. If the Boers have erred by undue harshness to the natives, colonists of British origin must not be entirely acquitted. And the fact must not be lost sight of that the native is not infrequently a most untrustworthy and lazy servant, as well as an inveterate drunkard if he can obtain access to alcohol.

The missionaries.

Foremost in championing the natives were the missionaries. The missionaries have been attacked not only by Dutch but by British colonists. Their zeal, it is certain, has frequently outrun their discretion. Their success in making converts, at least among the Bantu tribes, has been limited. Moreover, a longer experience of all the African negroid races has led to a considerable modification in the views originally held in regard to them. The black man is not simply a morally and intellectually undeveloped European, and education, except in rare instances, does not put him on a par with the European. There is a tendency in all the negroid races for mental development to cease at a much earlier age than in the European. But after all has been said against the extreme attitude of some of the missionaries, no unprejudiced man will deny that their work on the whole has been a good one. The fair fame of Great Britain has more than once been upheld in South Africa at the instigation and by the conduct of these intrepid pioneers. Moffat and Livingstone among the Bechuanas, Cassalis among the Basutos, Dr Stewart in Cape Colony, have all had a beneficent influence upon the natives around them. They have opposed the sale of alcohol, denounced inhumanity from the farmers, encouraged the men to labour and taught them mechanical arts. To-day technical education is still further taking the place of doctrinal discourse, and the effect is an excellent one.

Limits of British jurisdiction.

In 1836 an Act was passed which set a limit to the jurisdiction of the Cape Government in South Africa. It was entitled the Cape of Good Hope Punishment Act, and under it the Cape colonial courts were empowered to deal with the offences committed by British subjects in any part of South Africa up to the latitude of 25 degrees. The importance of the Act lies chiefly in the limit given to British powers at an early date. On the strength of it, the Boers who subsequently trekked away from the colonies were warned that by so trekking they did not pass out of the limits of British jurisdiction.

The Great Trek.

From 1836 to 1840 what is known as the Great Trek occurred. A number of the more turbulent spirits among the Boers, impatient of British rule, emigrated from Cape Colony into the great plains beyond the Orange river, and across them again to the fastnesses of the Zoutspanberg, in the northern part of the Transvaal. Various reasons for this trek have been assigned. Among the Boers of the Graaff Reinet and other frontier districts the tradition of rebellion against every form of civilized government had existed since the days of their first revolt against the East India Company. They now protested against what they considered the misrepresentation by the missionaries of their attitude towards the natives. They further objected that the wars on the Kaffre frontier were of a ruinous and disastrous character, and were not sufficiently dealt with by the Cape Government. Finally, what exasperated them beyond everything was the abolition of slavery. In relation to this trek, it is as well that the cause advanced by their leader Piet Retief in 1837 should be put on record. The manifesto dealt with various points, but the one in reference to the abolition of slavery ran as follows:—"We complain of the severe losses we have been forced to sustain by the emancipation of our slaves, and the vexatious laws which have been enacted respecting them." It was estimated that during the four years in which the trek lasted no less than 7000 persons took part in it. Sir Benjamin D'Urban, who was governor at the time, desired to stop the trek, but could find no means of doing so; and when urged by the colonial authorities to take some steps in the matter, he replied that he could see no means "of stopping the emigration except by persuasion and attention to the wants and necessities of the farmers."

At the outset misfortune appeared to dog the footsteps of these pioneers. They had no sooner crossed the Vaal river than they encountered the Matabele under Moselekatze. After an initial defeat at his hands, and the loss of much of their stock, they were eventually victorious, and in 1838 drove Moselekatze out of the country. Moselekatze having been defeated, the Boers, under Piet Retief, turned their attention to Natal, and marched towards the coast. Under the Drakensberg, while interviewing a chief of the Zulus named Dingaan, some sixty-five Boers under Retief were treacherously murdered by him. Other trekkers followed in the wake of Retief, and attacking Dingaan, avenged the massacre, although not before a number of Boers—men, women, and children—had been massacred by the natives at Weenen (the Place of Weeping). In July 1838 the British Government announced that they could not allow the establishment of an independent state by "any of Her Majesty's subjects, which the emigrant farmers continued to be." Sir George Napier, who had then been appointed governor, issued a proclamation warning the trekkers to return to the colony, and also stating that he should take immediate possession of Natal at an early date. Meanwhile the emigrant farmers had established what they called the Republic of Natalia, elected a Volksraad, and founded the town of Pietermaritzburg.

In 1841 the Volksraad of the "Natalia Republic" requested "that a free and independent state in the closest alliance with the British Government" might be recognized. In reply to this Sir George Napier wrote saying that "Her Majesty could not acknowledge the independence of her own subjects, but that the trade of the emigrant farmers would be placed on the same footing as that of any other British settlement upon their receiving a military force to exclude the interference with or possession of the country by any other European Power." To this the Volksraad in Natal replied that they had asserted and maintained their independence ever since leaving the colony, and they could not surrender it. Troops were then sent to the country, and several skirmishes occurred between the Boers and the British forces. At the conclusion of these a settlement was proposed by Mr Cloete, the British Commissioner, and eventually those Boers who had come down from beyond the Drakensberg withdrew, returning to their homes. Those remaining behind in the territories of Natal accepted the constitution of a British colony.

A feature in the policy of the British authorities at this time in South Africa, and one which arose out of the

Native treaty states.

strong representations of the missionaries, was the establishment of what were known as treaty states, in which the territory and rights of certain natives were defined. The first of these was made between Cape Colony and the chief of the Griquas, Andries Waterboer, in 1834. This treaty alleged that Waterboer was the "friend and ally" of the colony, and it also defined his boundary extending along the Orange river. It further agreed to supply him with a certain quantity of muskets and ammunition. Waterboer was the chief of some three or four thousand Griquas, a bastard race which had sprung up from the intercourse between Boers and native (principally slave) women. In 1843 two more of these treaty states were established, one under Adam Kok and the other under Moshesh. Adam Kok had under him a small number of Griquas, who dwelt in the country east of that occupied by Waterboer. And east of this country again was a tract of territory occupied by Basutos under Moshesh. In the same way Pondoland was established as a treaty state in 1844. At a later date it was found that in the country allotted to Adam Kok and his Griquas there were settled some thousand emigrant Boers. Thus the arrangement with Adam Kok naturally gave rise to a good deal of bitterness on the part of the Boers. They said it was not their intention to drive the coloured people from their dwellings, but it was their wish that they also should have their rights respected. Skirmishing between Boers and Griquas occurred, and eventually a force of 200 British troops was sent to the scene of disturbance. The result of this expedition was that Kok's territory was divided into two districts, one being retained exclusively for the natives, and the other for white men as well as natives. The government of both these territories was for a time under a British Resident. From the small station at which this agreement was drawn up the town of Bloemfontein eventually developed, and subsequently became the capital of the Free State. Difficulties arose at this time also in Basutoland with the natives, and Major Warden defined the Basutoland boundary. This boundary, known as the "Warden line," divided the Basutos from the emigrant Boers. Its definition did not by any means terminate the strife between Basuto and Boer.

Orange River Sovereignty.

In 1848 Sir Harry Smith proclaimed the country between the Vaal and Orange rivers British territory, under the name of the "Orange River Sovereignty." The battle of Boomplaats followed, in which Sir Harry Smith routed the Boers. Meanwhile the Boers were having considerable trouble amongst themselves on the northern side of the Transvaal, arranging for the government of their country. They eventually evolved a very unsatisfactory system, which was practically one of district governments. The result and extent of this system will be found described under TRANSVAAL. Sir Harry Smith, who was one of the most energetic, enterprising, and brave governors that South Africa ever had, and who had been responsible for the founding of the Orange River Sovereignty, was shortly after the establishment of the sovereignty reprimanded, and eventually recalled.

The Transvaal.

In 1852 the Boers, claiming complete supremacy in the district, turned back an Englishman who was travelling through Bechuanaland towards the interior (see BECHUANALAND). Livingstone's protest at this time was an important one, and his testimony as to the cruelty of the Boers towards the natives is of interest. The Boers plundered his house, destroying his books and taking away his goods. In 1852 the Sand River Convention was signed, which guaranteed to the Transvaal Boers the independence of their state.

Orange Free State.

In 1853 the Bloemfontein Convention was arranged by Sir George Russell Clark, on behalf of the British Government, with the Free State. Under this convention the Orange River Sovereignty was handed over to delegates appointed to receive it. Both in the Sand River and Bloemfontein Conventions clauses were inserted stating that Great Britain had no alliance whatever with any native chiefs or tribes to the north of the Orange and Vaal rivers, with the exception of the Griqua chief Adam Kok. It was further stipulated that neither the Transvaal nor the Orange River Government should permit slavery or trade in slaves in their territory. Numerous protests were made at the time, from many of the inhabitants of the Orange River Sovereignty, against the abandonment of it by the British Government, but the Duke of Newcastle, who was then in office, replied that the decision was inevitable, as British responsibilities in South Africa required restricting rather than extending, especially (he added) "as Cape Town and part of Table Bay were all she [England] really required in South Africa" (see ORANGE RIVER COLONY). The abandonment of the Orange River Sovereignty in the territory north of the Orange river, against the wishes at the time of many of the emigrant Boers, was the first great blunder made by the British Government in their dealings with the emigrants.

Sir George Grey.

When the Great Trek occurred, two courses obviously lay before the British authorities: either to let the Trek Boers go, and give them their blessing and liberty, or to repudiate and discourage the trek from the outset. The action taken by the British authorities was one of vacillation between these two courses. In the words of Mr Paul Botha, a Boer writer, England first blew hot and then blew cold. In 1854 Sir George Grey was sent to the Cape as governor. He had no sooner arrived than he addressed himself with energy and diligence to the great problems awaiting him. He at once resolved that in dealing with the natives the policy of continually fighting was not altogether satisfactory. Up to the time of his arrival little or nothing had been done in the matter of education, and he now determined, to the utmost of his ability, to encourage the dissemination of knowledge among the natives. He visited the kraals in British Kaffraria, and thoroughly acquainted himself with the peculiarities of the Bantu tribes. He then addressed himself to the missionaries of various denominations, and offered pecuniary aid in the establishment of large industrial schools, in which the boys should learn not only to read and write, but to work as mechanics, and where they should be trained in industrial habits. These societies and schools continued for some time, but were discontinued at a later date when the grant was curtailed. The school at Lovedale, however, still exists, and has continued to do good work. The plan of technical education among the Kaffres has recently been reintroduced, and is now received with more general favour.

In 1858 Sir George Grey, who had acquainted himself thoroughly with the South African Boers, proposed confederation between the various South African states. In making this proposition to Sir E. B. Lytton, he wrote at the time: "Experience has shown that the views which led to the dismemberment of South Africa were mistaken ones. In point of fact, her Majesty's possessions here are of great and yearly increasing value to the trade and commerce of Great Britain." As if to justify the sanguine prediction of Sir George Grey, the Free State, in December of the same year, having found that independence had brought numerous troubles in its train, and being weary of native wars, wrote to Sir George Grey,

conveying a resolution of their Volksraad in favour of federation with the Cape Colony. Sir George Grey was highly pleased to receive this communication, and urged the home authorities to adopt it. Unfortunately, his views with regard to federation and the reconciliation of the Dutch at this early stage did not meet with the approval of the British Government, and the proposition fell through. Sir George Grey had the mortification of seeing nearly every proposition he made rejected. In a despatch to the Colonial Office, on the 20th July 1859, he wrote as follows:—"With regard to any necessity which might exist for my removal on the ground of not holding the same views upon essential points of policy as her Majesty's Government hold, I can only make the general remark that during the five years which have elapsed since I was appointed to my present office there have been at least seven Secretaries of State for the Colonial Department, each of whom held different views upon some important points of policy connected with this country."

The request of the Free State Boers for federation with Cape Colony having been rejected, the inhabitants of the two republics were now left to develop their own institutions and government to the best of their ability. The Free Staters, owing chiefly to their acquiring at an early stage a most enlightened and liberal leader in President Brand, were fairly successful. The turbulence and continued unrest of the Transvaal Boers, on the other hand, kept their country in a state bordering on chaos (see TRANSVAAL). In 1877 the Transvaal once more came under British rule.

British and Dutch.

Up to the year 1870 the Dutch considerably outnumbered the British inhabitants not only in Cape Colony but throughout South Africa. At the time of the British annexation of Cape Colony the colonists were entirely of Dutch and Huguenot extraction, and although the settlers of 1820 had brought a British element among the colonists, and an element which has thriven and prospered, the Dutch continued, even after the Great Trek, to be considerably in a majority. The industries of the colony were almost entirely pastoral, and remained chiefly in the hands of the Dutch. Continual feuds with the Kaffres, and also the continual desire to trek into new countries, all tended to keep back farming as an industry, and the country in the years 1867 to 1870 was in a generally very depressed condition. The Zulus during these years went on foraging expeditions into the Transvaal, and threatened Natal. The Basutos were continually at feud with the Free State. The Kaffres had a series of wars, preceded usually by massacre, chiefly with the British colonists on the eastern frontier of Cape Colony. In 1870 a new era opened for South Africa. The era of commercial expansion began. In that year, following smaller finds of diamonds on the banks of the Vaal and Orange rivers, the diamond mines of Du Toits Pan and Bultfontein were opened up. In 1869 gold had been found in the Lydenburg and Zoutpansberg districts in the Transvaal, and diggers had resorted there from different parts of the world; moreover, farther up the country, in the territories of Mashonaland, Bain had reported discoveries of gold. Among the purely pastoral population ostrich-farming became a new industry, and added a considerable asset to the wealth of the colony. The revenue derived from the export of ostrich feathers in 1899 was recorded at half a million. It was, however, the mineral discoveries of diamond and gold that chiefly determined a new departure in the development of the country. Emigration, which had been going on slowly for some time past, now largely increased. Men rushed to the diamond fields, and in smaller numbers to the new gold fields of the Transvaal. From that time the immigration of Europeans of other than Dutch extraction went steadily on. The extension of railways, the influx of capital, the providing of markets for the produce of the country, were all due to the opening up of the gold and diamond mines. As the development of these industries proceeded, the line which divided the Boers from the colonists of British extraction became more clearly marked. It was soon evident that the Boer had little faith in and less capacity for mining, either as a digger on the diamond fields or as a prospector on the new gold-fields. He remained on his farm, content to reap such benefit as might be derived from the sale of farms at greatly enhanced prices, and also with what he could obtain in the way of cash for the small products he was able to offer in the various mining camps. On the other hand, a large mining population soon grew up, first of all at Kimberley, afterwards in and around Lydenburg and Barberton, and finally at Johannesburg—a population modern in its ideas, energetic, educated, cosmopolitan, appreciating all the resources that modern civilization had to offer them, and with a strong partiality for the life of the town or the camp rather than that of the farm and the veldt. The Boers remained very much what they had been in the 17th century. Their life of continual strife with natives continual trekking to fresh pastures, had not been conducive to education or the acquirement of civilization. In religion they were puritanical, fanatic, and their old traditions of Dutch East India government, together with their relation to the natives, undoubtedly developed a spirit of caste and even tyranny.

In the competition which now set in for such wealth as is won in cities, the Boer found himself hopelessly handicapped. From Cape Town to the north of the Transvaal a considerable difference has always existed amongst the inhabitants of Dutch origin. Beginning with the Dutch of Cape Town and the Western Province, many are enlightened gentlemen, who are well educated themselves and have sent their sons to European universities. Farther out in the Graaff Reinet and other districts of Cape Colony a more primitive life obtains among the Dutch, and in the Free State existence was of even a simpler character. Nevertheless, the history of the Free State, under the masterly presidency of Brand, shows that the Boers of that country evinced a considerable knowledge of the advantages of civilization, and in a measure endeavoured to increase them. Farther north, again, the Boer is a wilder and more turbulent spirit, as the history of the Transvaal down to 1877 testifies, until on the northern frontier of the Transvaal are to be found some of the wildest specimens of white men anywhere extant on the face of the globe. A race of hunters, and it is to be feared of slave-owners, they respected neither the laws of their own people nor sometimes those of humanity. The Boers were a prolific race, and in spite of all their losses from war, pestilence, famine, and other causes, they continually increased in numbers, if not in civilization. This increase did not, however, keep pace with the continual inflow of immigrants which began about 1870, and in 1872 we find the European inhabitants of the diamond fields returned at 35,000.

Sir Bartle Frere and confederation.

It was at this stage of affairs that responsible government was granted to Cape Colony. From that time down to the annexation of the Transvaal in 1877, to quote once more the homely phrase of Mr Botha, Great Britain "blew hot" in South Africa. Lord Carnarvon was Secretary of State for the Colonies, and in 1876 he appointed Sir Bartle Frere as High Commissioner of South Africa. Sir Bartle Frere's special mission was to further the confederation of the

states of South Africa, and in making the appointment Lord Carnarvon went so far as to express to Frere the hope that he would be the first governor-general of the South African Dominion. Meanwhile things had reached a critical stage in the Transvaal: the treasury was empty; the two factions were in open feud with one another; President Burgers was unable to raise taxes; the Boers were threatened with invasion from the Zulus, and were unable to suppress a native rising within their own territories. Under these circumstances, on 12th April 1877 Sir Theophilus Shepstone, who had been sent to Pretoria to investigate the state of affairs, annexed the Transvaal to Great Britain. Shepstone did not take this step until he had convinced himself that it was the only step which could save the Transvaal from ruin. His motive and the evidence which was before him are fully discussed under TRANSVAAL. In 1880 a change occurred in the Government of Great Britain, and with it there occurred another of those alterations of policy which have been so disastrous in South Africa. Great Britain once more "blew cold." Mr Gladstone returned to power, and with his return the hopes of the dissatisfied Boers in the Transvaal, who were already agitating for retrocession of the country, were still further encouraged. In 1880 the fate of Sir Harry Smith and Sir George Grey overtook Sir Bartle Frere. Frere, whose coming had been heralded with such encouraging messages, was recalled. In October 1880 he received a cablegram from Lord Kimberley that "there has been so much divergence between your views and those of her Majesty's present Government on South African affairs, that . . . they have with regret come to the conclusion that her Majesty should be advised to replace you by another Governor." It was such vacillation as this on the part of Home Governments which won for South Africa the title of "the grave of reputations." An article in the *Nineteenth Century* in 1880 by Sir Bartle Frere exactly expresses the attitude of the Transvaal Boers, and shows a true insight on the part of the writer:—

Annexation of Transvaal.

> "What the Boers individually wished for [he wrote] was individual independence of law and government generally, not of this or that foreign Government, but to obey no one by force of law; to be far from power of compulsion; to see, as they put it, no other man's smoke; to be free and unfettered in the wilds. This was the object of their aspirations. For national life and national independence they had a sentiment; but for national liberty they were not willing to make any sacrifice of individual licence or power to refuse obedience to law. The limits within which such freedom was possible had been reached before Mr Burgers undertook to attempt the task of governing."

The recall of Sir Bartle Frere was followed by a rebellion among the Boers in the Transvaal. In 1881, after a series of severe skirmishes terminating in the battle of Majuba, where the Boers were entirely victorious over the British forces, a treaty was signed between Sir Evelyn Wood and the Boer generals, and once more the Transvaal was recognized as an independent state. The terms on which this independence was granted were clearly defined, first of all in the Pretoria Convention of 1881, and subsequently in the London Convention of 1884. The boundaries of the Transvaal were defined in both conventions, the right of control in all foreign relations was retained by her Majesty's Government, and the suzerainty of the Queen was reserved. On these conditions the independence of the Transvaal in the conduct of its own affairs was duly recognized. In 1882 the Afrikander Bond, which had its origin at Bloemfontein and the Paarl, came into existence, and was joined by members in the Free State, Transvaal, and Cape Colony. The Cape Colony branch of the Bond dissociated itself later from those in the republics. With regard to the formation of the Bond, it is only fair to say that although the Bond partially originated in Bloemfontein, it was strongly denounced and openly discouraged by President Brand, then ruling the Free State. From this time forth the Dutch in South Africa on all political questions divided into two camps. These two camps were represented by President Kruger and his intriguing following in the Transvaal, and by President Brand, with an enlightened following of Free State Boers, in the Orange Free State. In Cape Colony, on the other hand, there was Mr Hofmeyer, at the head of the Bond, with a number of followers in intimate correspondence and relationship with Mr Kruger, while a small number of enlightened Dutchmen held aloof (see CAPE COLONY).

Transvaal rebellion and retrocession.

The Afrikander Bond.

From the signing of the Pretoria Convention the Transvaal Boers, who had never respected their own laws, showed that they had very little intention of respecting conventions. They raided over their borders to the west, north, and east. In the east they established the "New Republic" in Zululand, and on the west the republics of Stellaland and Goshen in the territories of Bechuanaland. Their aggressive action in Bechuanaland led, in 1884, to the Warren expedition, which expelled the Boers from Bechuanaland and compelled them to remain within their borders. It was about this time that Mr Hofmeyer thought it expedient to modify the extreme tone of his Bond policy, and that Mr Rhodes became a factor in Cape politics. The Warren expedition was clear evidence to the Bond and the rest of South Africa that whatever else Great Britain might contemplate, she did not propose either to withdraw or give up all claims to supremacy in South Africa.

The Conventions.

The year 1883 saw the introduction of another European Power into South Africa. The German flag was hoisted over Germany's first colony on the shores of Angra Pequeña Bay, in Damaraland. German missionaries had been settled on this coast for some time, and had previously on more than one occasion asked both the Imperial and Cape Colony Governments for protection. In 1878 Sir Bartle Frere had urged the British Government to respond to these appeals, saying that if they were neglected Germany would certainly step in. The result was the annexation to Great Britain at that time of Walfish Bay, with a small strip of territory adjoining. This port was handed over to Cape Colony in 1884. Meanwhile the colonial party in Germany had used their influence to obtain further expansion, and in August of 1884 Germany finally annexed 322,450 square miles of country, with a coast-line of 930 miles, excluding the small strip of British territory in the vicinity of Walfish Bay. The greater portion of German South-West Africa is a desert and barren country, and at the time of annexation was stated to contain between 2000 and 3000 white inhabitants and about 200,000 natives, chiefly Bantu. In September of the same year a German explorer, Herr Einwald, proposed to take possession on behalf of Germany of St Lucia Bay, on the coast of Zululand. After some correspondence between Great Britain and Germany, it was eventually arranged that Germany should make no annexation on the east coast of Africa south of Delagoa Bay. The whole of Zululand is now a portion of the colony of Natal.

Germany in South Africa.

After the retrocession of the Transvaal in 1881, and the re-establishment of the country under British suzerainty as an independent state, the attention both of the Boers and Europe was turned to Delagoa Bay. In order to

understand the complications which now arose with regard to this port, it will be well to review briefly the history of the territories in which Portugal had from time to time maintained settlements since the end of the 15th century. Vasco de Gama discovered Delagoa Bay in 1498, and it became the site of a small settlement similar to those established at the same time on the west coast of South Africa by the Portuguese. The history of these settlements since their foundation has remained, at least to the world at large, almost unknown. In 1899 investigations among various Portuguese archives at Lisbon and the British Museum in London were undertaken, on behalf of the Cape Colony Government, by Dr Theal, the well-known Cape historian, with a view to obtaining some details as to the records of colonization in these districts. From these researches, and also from the interesting record of events compiled by Mr Pratt in his *Leading Points of South African History*, the following facts have been gathered. The voyages of the early Portuguese navigators were very minutely described by Portuguese historians. They were full of adventure by sea and land. Of those who succeeded Diaz and De Gama, the most distinguished navigator and administrator was D'Albuquerque. He reduced Goa to submission and made it the capital of Portuguese India, of which the coast of Africa formed part. Forts were established at Sofala and Kilwa. Two armed fleets were maintained to keep the seas, the one from Cape Guardafui to the Gulf of Cambay, the other from the Gulf of Cambay to Cape Comorin. This state of things did not, however, last very far into the 16th century; and as Holland, England, and France took up the Eastern trade, that of Portugal declined, and with it also declined the settlements on the African coast. For three hundred years these Portuguese settlements remained depôts of trade, chiefly in gold and ivory, at times being practically abandoned, and again being used in slave traffic. In 1868 Pretorius, then President of the Transvaal, attempted to annex Delagoa Bay, on the pretext that it formed the natural outlet of the Transvaal to the sea. Thereupon both Portugal and Great Britain advanced claims to the port, and the whole matter was eventually referred in 1872 to the President of the French Republic for arbitration. In 1875 an award was given by the French President, Marshal MacMahon, entirely in favour of the Portuguese. While the inquiry was proceeding, an agreement had been come to between Great Britain and Portugal that whichever of them should obtain possession of the Bay, should give the right of pre-emption to the other. Previously to the arbitration the Boers had withdrawn their claim in favour of that of Portugal, on an understanding with the Portuguese that, should the award be given in their favour, they should allow the South African Republic special facilities for the importation of goods, and allow many of them to enter the state duty free. In fulfilment of this understanding a treaty was signed between Portugal and the South African Republic in 1875 granting these privileges, and also consenting to the construction of a railway from the port. President Burgers endeavoured to raise the capital necessary for the building of this railway, but only succeeded in obtaining a portion in Europe, and the scheme fell through. In 1883 an American, Colonel MacMurdo, succeeded in obtaining from the Portuguese Government a concession for the building of a railway from Delagoa Bay to the Transvaal frontier. In 1889 the Portuguese Government arbitrarily seized the railway, which was then open to Komati, the point contracted for and shown in the Portuguese plans, on the alleged ground that the "frontier" was really at a point five miles nearer to Pretoria. This alteration of the boundary and seizure of the railway, it was freely stated at the time, was done at the instigation of the Transvaal. As both American and British subjects were interested in this concession, a strong protest was made to Portugal at the time by the United States and Great Britain. Again the matter was referred to arbitration, on this occasion the tribunal being appointed by the Swiss Government. After a session of no less than ten years, Portugal was, on 29th March 1900, ordered by the court to pay compensation to the holders of the MacMurdo concession. The total amount disbursed was over £900,000. The amount awarded was less than was anticipated, but it was the award of an independent court, and at least went to show that the action of the Portuguese had been unjustifiable (see also ARBITRATION, INTERNATIONAL). In 1895 the Delagoa Bay railway was extended by the Netherlands Railway Company to Pretoria. In the drama of South African history the Portuguese states have not played an important part. Boundary disputes have occurred from time to time with both their Boer and their British neighbours, but with the exception of a few skirmishes in the early days of the British South Africa Company, these have been satisfactorily settled. What interest the Portuguese colonies have aroused in modern times has been centred round Delagoa Bay. While the Transvaal retained its independence, Delagoa Bay, as a port outside British control, was a source of strength to the Boers. Both President Kruger and his Hollander and German advisers interested in the railway concentrated their efforts on a close relationship with Portugal. In the war which began in 1899 munitions of war and recruits for the Boers were freely passed through Delagoa Bay.

Delagoa Bay.

In order to pursue the course of events in South Africa, it is now necessary to return to the British colonies and the Boer republics. If the year 1870 is memorable as marking the dawn of a great commercial era in South Africa, so must 1881 be taken to mark the beginning of a disastrous political period. It is well that the events from 1877 (the date of the British annexation of the Transvaal) onwards should be clearly remembered. In the first place, the Zulu power, which had so long menaced the Transvaal, was broken in 1878 by British forces, and by the expenditure of British money to the extent of £6,000,000, with practically no assistance from the Boers. Within the Transvaal the Bantu tribe, under Secocoeni, another native tribe in Boer territory, was defeated by a British force under Sir Garnet Wolseley. In 1881 the Transvaal was not only again independent, but the amount of its debt was funded and advanced by Great Britain. The Afrikander Bond was founded, with the deliberate intention on the part of its Boer promoters of forming a United States of South Africa under a Dutch flag. The raiding over both east and west boundaries which the Transvaal Boers continued to carry on in the face of conventions was a part of this policy.

The Boer Republic, 1881-87.

The Warren expedition, which cost over £1,000,000, had the effect of checking for a time the extreme ambition of the Dutch party throughout South Africa. Mr Hofmeyr, the leader of the Bond in Cape Colony, considerably moderated his attitude, and in 1887 proposed a Zollverein scheme for the whole British Empire. In the Free State President Brand continued to make his influence felt with the Boers of both republics, insisting upon the importance of a peaceful development of the country and friendly co-operation with the British Government. Mr Kruger remained implacable, bigoted, avaricious, determined on a policy of isolation and exclusion. The

old Transvaal dream which Brand had denounced in the early days (see TRANSVAAL) was now revived and adopted with redoubled fervour. President Kruger would have a seaport of his own, or, if not, Delagoa Bay should have a monopoly of the trade. The Transvaal would enter into an alliance with the Free State, and British trade was to be rigidly excluded. In 1887 a conference was held at Pretoria with delegates from the Free State. The proceedings reveal the gulf existing between the adherents of Kruger and the adherents of Brand (see CAPE COLONY, TRANSVAAL, and ORANGE RIVER COLONY). On the one hand was an undying hatred of Great Britain, combined with a deep scheme of ultimate attack upon British supremacy throughout South Africa; and on the other was a desire to work amicably with all the white races of South Africa for their mutual benefit and the prosperity of the country.

Free State and Transvaal conference.

The conference was followed by a personal visit from President Kruger to President Brand at Bloemfontein. The result was a complete failure to arrive at any treaty whatever. Brand refused to be ensnared in the wild intriguing policy of President Kruger, and while he lived the Free State held aloof. Meanwhile the great gold-fields of Johannesburg, which had been discovered in 1886, were developing by leaps and bounds, and by 1889 the population equalled that of Kimberley. Once more there occurred that rapid increase of the British and European (other than Dutch) population in South Africa, which from the beginning of the mineral discoveries has steadily gone on. From Cape Colony railways continued to be extended towards the new centres of wealth. In 1885 Kimberley was reached, and in 1890 this line was extended to Vryburg in Bechuanaland. In 1889 the Cape railway was extended to Bloemfontein, and in 1892 it reached Johannesburg.

Under the influence of a rapidly increasing revenue from the gold-fields and that system of trade monopolies which Mr Kruger had introduced, the Government of the Transvaal gradually brought into existence a large privileged class of concessionaries and office-holders, until at the outbreak of the war in 1899 one burgher out of every five in the Transvaal held some office or another. The effect of this development was the production of a body of officials in the Transvaal, partly Hollander and German, partly Boer, the majority of whom were very poorly educated, and the whole of whom were pledged supporters of Mr Kruger's Government in any policy, however extravagant, which he might choose to adopt. The Government grew narrower, more exclusive, and more entirely monopolist with every year of its existence. It would almost appear as if Mr Kruger had deliberately set himself to copy the model of the Dutch East India Company at the Cape, of which Watermeyer wrote in 1857 that it was "in all things political, purely despotic; in all things commercial, purely monopolist." Meanwhile

Afrikander Imperialists.

at the Cape there was growing up a party of South African Imperialists, or, as they have been called, Afrikander Imperialists, who came to a large extent under the influence of Mr Rhodes. Among these were Mr W. P. Schreiner and Mr J. W. Leonard, and apparently even to some extent Mr Hofmeyr. From the time of his entrance into politics Mr Rhodes endeavoured to induce the leading politicians and colonists in Cape Colony to realize that a development of the whole country could and should be accomplished by South Africans for South Africans. He fully admitted that the cry which had become so popular since 1881 of "Africa for the Afrikanders" expressed a reasonable aspiration, but he constantly pointed out that its fulfilment could best and most advantageously be sought, not, as the Kruger party and extremists of the Bond persisted in saying, by working for an independent South Africa, but by working for the general development, progress, and prosperity of South Africa on democratic, self-reliant, self-governing lines, under the constitution and beneficent shelter of British colonial rule and the British flag. An independent South Africa such as the Kruger party desired might have resulted in a so-called republic. But such a republic would have been a stranger to all true liberty and equality of rights: it would rapidly have become a prey to the same sort of faction, strife, and anarchy as had obtained in the Transvaal. Mr Hofmeyr's attitude became considerably modified after the Warren expedition. In that year (1884), having the power in his hands at the time of the fall of the Scanlen Ministry, he put Mr Upington into office, with Sir Gordon Sprigg as his colleague. In 1886 Sir Gordon Sprigg became Premier; and in 1890 he was succeeded by Mr Rhodes, who took office with the approval and support of Mr Hofmeyr. Mr Rhodes remained in office as Prime Minister until 1896. During this period of Mr Rhodes's life the part he played in the development and public life of South Africa was greater than that of any other man.

British South Africa Company.

In 1888 Mr Rhodes had succeeded in inducing Sir Hercules Robinson to send Mr Moffat, the missionary, to enter into a treaty with Lobengula, the Matabele chief. Under this treaty Lobengula bound himself not to make a treaty with any other foreign Power, nor to sell or in any other way dispose of any portion of his country without the sanction of the High Commissioner. By this step the country was secured from both the Portuguese and the Dutch, both of whom, more especially the latter, were already making overtures with the object of obtaining the country for themselves. This treaty was followed by the formation of the British South Africa Company, under royal charter (see RHODESIA and CHARTERED COMPANIES) in 1899, and the occupation of Mashonaland by the pioneer expedition in 1890. In 1891 a skirmish was fought with Portuguese forces. In 1893 a war was fought with the Matabele by Dr Jameson, then administrator of Mashonaland, and Bulawayo was occupied. The name Rhodesia was conferred upon the whole country by general consent in 1894. During the whole of these stirring events Mr Rhodes, in addition to being Premier of Cape Colony, was also managing director of the British South Africa Company, and responsible for the conduct of its affairs. He further occupied the position of chairman of the De Beers Consolidated Mines (the great diamond mining corporation in Kimberley), and was busily engaged in developing plans, in conjunction with Mr Alfred Beit, for an extension of the telegraph from Cape Town to Cairo, and the pushing forward of railway communication into the heart of Africa. The political effect of this northern movement was definitely to limit the northern boundary of the Transvaal. Living in Cape Town and at the head of the Government, Mr Rhodes used every effort in his power to demonstrate to the Cape colonists that the work he was doing in the north must eventually be to the advantage of Cape Colonists and their descendants. By this means he checked opposition to the movement which sentimental sympathy with the Transvaal Boers tended to develop under the pretext that the Transvaal, by reason of its proximity, had some sort of reversionary right to the country lying to the north. On the whole, Mr Hofmeyr and his friends were well pleased at having secured the co-operation of the "big Englander" Rhodes, or, as he was at one time called by Mr Merriman, the "young burgher."

In 1891 the Bond Congress was held at Kimberley, and harmony appeared to reign supreme. During his term of office Mr Rhodes addressed himself to bringing together all interests, as far as it was practicable to do so. He showed that his views of the situation were broad and statesmanlike. The directions in which practical progress was made were the steady development of inter-state and inter-colonial railway systems, and the establishment, as far as possible, of common customs, tariffs, and inter-colonial free trade under a customs union. The persistent opponent to both these measures was the Transvaal. In matters of colonial domestic legislation, referring to taxation, native questions, and excise, Mr Rhodes fell in to a considerable extent with Dutch prejudices. The leaders of the Cape Dutchmen apparently thought they might some day win Mr Rhodes to independent republicanism, while, on the other hand, Mr Rhodes endeavoured to demonstrate to the colonists, Dutch and British alike, that those very privileges which theoretically are associated with republicanism were practically more fully obtainable in an enlightened self-governing British colony. Afrikander Imperialism thus became a definite and living policy, and it was about this time that the term "progressive" came to be associated with the party which supported it.

Rhodes and the Bond.

Meanwhile the Kruger faction and retrogression were rampant in the Transvaal. In 1892 there began in that country what has since come to be known as the first reform movement. The National Union was founded at Johannesburg by ex-Cape Colonists of the Imperial progressive party. The first chairman was Mr Tudhope, who had held office in the Cape Ministry, and he was ably supported by the Hon. J. W. Leonard, at one time Cape Attorney-General, and his brother Mr Charles Leonard. For three years petitions and deputations, public meetings and newspaper articles, the efforts of the enlightened South African party at Johannesburg and Pretoria, were all addressed to the endeavour to induce President Kruger and his Government to give some measure of recognition to the steadily increasing Uitlander population. The President remained as impenetrable as adamant. Any measures he did take were retrogressive rather than progressive, intended still further to conserve the burgher privileges and exclude the Uitlander from any part or lot in the affairs of the State. Nine-tenths of the state revenue was contributed by the Uitlanders, yet, practically speaking, neither for them nor for their children were political privileges to be accorded. The Uitlanders had not even any municipal power. At this juncture a conspiracy was entered into between Mr Rhodes, Dr Jameson, and certain of the Uitlander leaders which led to the Jameson Raid. In conjunction with this conspiracy, and in order to lay before South Africa the true position of affairs in the Transvaal, as well as to give President Kruger a final chance to meet the Uitlanders, Mr Charles Leonard issued a manifesto as chairman of the National Union, the terms of which are memorable both for the completeness with which the Uitlander case was stated and for the fact that the claims advanced therein were those which the High Commissioner and the British Government very largely supported in 1899. This manifesto, the full text of which may be found in the appendix to Mr Fitzpatrick's *The Transvaal from Within*, concludes as follows :—

First Transvaal reform movement.

"We have now only two questions to consider: (*a*) What do we want? (*b*) How shall we get it? I have stated plainly what our grievances are, and I shall answer with equal directness the question "What do we want?" We want (1) the establishment of this Republic as a true Republic; (2) a Grondwet or Constitution, which shall be framed by competent persons selected by representatives of the whole people, and framed on lines laid down by them—a Constitution which shall be safeguarded against hasty alteration; (3) an equitable franchise law, and fair representation; (4) equality of the Dutch and English languages; (5) responsibility of the Legislature to the heads of the great departments; (6) removal of religious disabilities; (7) independence of the courts of justice, with adequate and secured remuneration of the judges; (8) liberal and comprehensive education; (9) efficient civil service, with adequate provision for pay and pension; (10) free trade in South African products. That is what we want. There now remains the question which is to be put before you at the meeting of 6th January, namely, How shall we get it? To this question I shall expect from you an answer in plain terms according to your deliberate judgment."

The conspirators believed that President Kruger and the burghers would realize the peril of further withholding redress of grievances, and be induced to do by force what he had always refused to do in deference to mere reason. The conspiracy entirely failed, and the Uitlanders were left in a worse plight than ever, although while Johannesburg was partially armed Mr Kruger had promised a consideration of grievances—a promise which was never fulfilled (see TRANSVAAL). The Reform leaders, sixty-four in number, were imprisoned at Pretoria, and the Uitlanders were now deprived of their services; for although the long terms of imprisonment were not carried out, under the agreement on which the reform prisoners were liberated in May 1896, they were bound to take no part or in any way interfere in politics for three years. Mr Rhodes's complicity in the Jameson Raid compelled him to resign his position as Premier of Cape Colony; and in 1896 he went to Rhodesia in time to take an active part in the suppression of the Matabele rebellion, which had occurred shortly after the surrender of Dr Jameson's force in the Transvaal.

Sir Gordon Sprigg took office for the third time as Premier of Cape Colony, in succession to Mr Rhodes, and in 1898 he was succeeded by a Bond ministry under Mr W. P. Schreiner. In 1896 and 1897 feeling ran very high throughout South Africa over the Jameson Raid controversy. The grievances under which the Uitlanders suffered were lost sight of; President Kruger proceeded on his retrogressive course unchecked in the Transvaal; while in the Free State Mr Steyn used the Raid as an electioneering cry during his contest for the Presidency, to work up the race feelings of the Free State burghers. Mr Fraser, who had been born and brought up in the Free State, and who was a supporter of the more enlightened policy followed, while living, by President Brand, was defeated by Steyn by a large majority. In Cape Colony the cleavage between the Progressives and the Bond party, although not more real, was more openly expressed than it had ever been before. The term "Progressive" was now formally adopted by the British mercantile communities in the various large towns and among the sturdy farmers of British descent in the Eastern Province. On returning to South Africa after the Raid inquiry at Westminster in 1897, Mr Rhodes had intended to withdraw from Cape politics and devote his energies entirely for a time to the development of Rhodesia, but the pressure put upon him by a section of the British colonists was so strong that he determined to throw in his lot with them and assist the Progressive party by every means in his power. In 1898 the Sprigg Ministry was defeated over a Redistribution Bill by which they hoped to secure more adequate representation for the Progressives, and Mr W. P. Schreiner became Prime Minister.

In 1897 Sir Alfred Milner had been appointed High Commissioner of South Africa and Governor of Cape Colony, in succession to Lord Rosmead. He at once addressed himself to a careful study of the situation, visiting

every part of the colony and obtaining a considerable command of the Cape Dutch language. In March 1898 he felt that the time had come when he should enter a public remonstrance with those Dutchmen in Cape Colony who avowedly encouraged President Kruger and the Transvaal Government in injustice to the Uitlanders and hostility to Great Britain. The remonstrance was moderately stated in a speech delivered at Graaff Reinet, and was of so important a character that it is advisable to reproduce a portion of it:—

Sir Alfred Milner.

"For my own part, I believe the whole object of the people for espousing the cause of the Transvaal is to prevent an open rupture between that country and the British Government. . . . They think that if they can only impress upon the British Government that in case of war with the Transvaal it would have a great number of its own subjects at least in sympathy against it, that is a way to prevent such a calamity. But in this they are totally wrong, for this policy rests on the assumption that Great Britain has some occult designs on the independence of the Transvaal. . . . But that assumption is the exact opposite of the truth . . . it is not any aggressiveness on the part of Her Majesty's Government which now keeps up the spirit of unrest in South Africa. It is that unprogressiveness—I will not say retrogressiveness—of the Government of the Transvaal, and its deep suspicion of the intention of Great Britain, which makes it devote its attention to imaginary external dangers, when every impartial observer can see perfectly well that the real dangers which threaten it are internal. Now, I wish to be perfectly fair. Therefore let me say that this suspicion, although absolutely groundless, is not, after all that has happened, altogether unnatural. I accept the situation that at the present moment any advice that I could tender, or that any of your British fellow-citizens could tender, in that quarter, though it was the best advice in the world, would be instantly rejected because it was British. But the same does not apply to the Dutch citizens of this colony, and especially to those who have gone so far in the expression of their sympathy for the Transvaal as to expose themselves to these charges of disloyalty to their own flag. Their goodwill, at least, cannot be suspected across the border; and if all they desire—and I believe it is what they desire—is to preserve the South African Republic and to promote good relations between it and the British colonies and Government, then let them use all their influence, not in confirming the Transvaal in unjustified suspicions, not in encouraging its Government in obstinate resistance to all reform, but in inducing it gradually to assimilate its institutions, and—what is even more important than institutions—the temper and spirit of its administration, to those of the free communities of South Africa, such as this colony or the Orange Free State. That is the direction in which a peaceful way out of these inveterate troubles, which have now plagued this country for more than thirty years, is to be found."

After this the colonists realized that in the High Commissioner they had a man of resolution, ability, and straightforwardness to deal with. The accession to power of a Bond Ministry at this juncture made the High Commissioner's position one of considerable difficulty. Affairs in the Transvaal were steadily going from bad to worse. An Industrial Commission, appointed by President Kruger in 1897 to inquire into a number of grievances affecting the gold industry, had reported in favour of certain reforms. The recommendations of the Commission, if adopted, would have done something towards relieving the tension, but President Kruger and his executive refused to be guided by them. Once more the Uitlanders determined to make a further attempt to obtain some redress by constitutional means, and the second organized movement for reform began by the formation in 1897 of a branch of the South African League. In 1898 Dr Leyds retired from the position of State Secretary in the Transvaal, and repaired to Europe as minister at large to the South African Republic. What the precise terms of that appointment may have been is unknown to history, but they apparently included the wearing of a picturesque uniform and the administration of secret service funds, which were chiefly expended on various organs of the Continental press. Dr Leyds was succeeded as State Secretary by Mr Reitz, ex-President of the Orange Free State. The change was certainly not for the better. Mr Reitz had ever since 1881 been one of the most pronounced anti-British Dutchmen in South Africa. He had co-operated with Borckenhagen in founding the Afrikander Bond. When elected President of the Free State in succession to President Brand, he utterly departed from the policy to which Brand had always adhered, and instead of continuing to hold aloof from the Transvaal, he entered into an offensive and defensive alliance with it. In him Mr Kruger found as willing, if not as skilful, an instrument as in Dr Leyds. At the end of 1898 the feelings of the Uitlanders were wrought up to fever pitch. The police service, which was violent where it should have been reasonable, and blind where it should have been vigilant, had long been a source of great irritation. On 18th December a Boer policeman, in pursuit of an Englishman named Edgar, whom he wished to arrest for an alleged assault on another man, entered his house and shot him dead with a revolver. The deepest indignation was aroused by this incident, and was still further increased by the trivial way in which the case was dealt with by the court. In 1899 matters reached a climax. After an ineffectual attempt to get a petition forwarded in December of 1898, the Uitlanders handed to the High Commissioner in March 1899 a petition to her Majesty with 21,684 signatures attached to it. The petition was accepted by Sir Alfred Milner and forwarded to London. This historic document will best serve to illustrate the course of events in the Transvaal after 1896, and also to show the status the Uitlander had arrived at in 1899. It is given in full in *The Times' History of the War*. The following extracts convey its general tenor and purport:—

Second Transvaal reform movement.

"29. The condition of Your Majesty's subjects in this State has become well-nigh intolerable.

"30. The acknowledged and admitted grievances of which Your Majesty's subjects complained prior to 1895 not only are not redressed, but exist to-day in an aggravated form. They are still deprived of all political rights, they are denied any voice in the government of the country, they are taxed far above the requirements of the country, the revenue of which is misapplied and devoted to objects which keep alive a continuous and well-founded feeling of irritation, without in any way advancing the general interest of the State. Maladministration and peculation of public moneys go hand in hand, without any vigorous measures being adopted to put a stop to the scandal. The education of Uitlander children is made subject to impossible conditions. The police afford no adequate protection to the lives and property of the inhabitants of Johannesburg; they are rather a source of danger to the peace and safety of the Uitlander population.

"32. Wherefore Your Majesty's humble petitioners humbly beseech Your Most Gracious Majesty to extend Your Majesty's protection to Your Majesty's loyal subjects resident in this State, and to cause an inquiry to be made into grievances and complaints enumerated and set forth in this humble petition, and to direct Your Majesty's representative in South Africa to take measures which will secure the speedy reform of the abuses complained of, and substantial guarantees from the Government of this State for a recognition of their rights as British subjects."

When this document was received at the Colonial Office in London, and its contents were made public, the British nation realized that Mr Kruger and his Government must either be mended or ended. In February 1899 Mr Kruger received a despatch from the British Secretary of State for the Colonies, Mr Chamberlain, protesting against his proposal to extend the dynamite monopoly for a further period of fifteen years, and pointing out that the monopoly was a breach of the Convention. There then followed a long series of despatches and correspondence on the various points at issue. On the dynamite question proposals were made on behalf of the Transvaal Government, through Mr Lippert, to the heads of the large mining houses in Johannesburg; but as President Kruger coupled them with impossible conditions, nothing came of them. On 4th May 1899 Sir Alfred Milner felt it his

duty to report at some length by cable to Mr Chamberlain. The concluding passages of this message sum up the whole South African situation in a masterly manner, and show the effect that was being produced by Mr Kruger's attitude not only in the Transvaal among the Uitlanders, but throughout South Africa. The telegram undoubtedly carried great weight in helping Mr Chamberlain to frame his policy. The concluding passages were as follows:—

The case for British intervention.

"The case for intervention is overwhelming. The only attempted answer is that things will right themselves if left alone. But, in fact, the policy of leaving things alone has been tried for years, and it has led to their going from bad to worse. It is not true that this is owing to the Raid. They were going from bad to worse before the Raid. We were on the verge of war before the Raid, and the Transvaal was on the verge of revolution. The effect of the Raid has been to give the policy of leaving things alone a new lease of life, and with the old consequences.

"The spectacle of thousands of British subjects kept permanently in the position of helots, constantly chafing under undoubted grievances, and calling vainly to Her Majesty's Government for redress, does steadily undermine the influence and reputation of Great Britain, and the respect for British government within the Queen's dominions. A certain section of the Press, not in the Transvaal only, preaches openly and constantly the doctrine of a Republic embracing all South Africa, and supports it by menacing references to the armaments of the Transvaal, its alliance with the Orange Free State, and the active sympathy which, in case of war, it would receive from a section of Her Majesty's subjects. I regret to say that this doctrine, supported as it is by a ceaseless stream of malignant lies about the intentions of the British Government, is producing a great effect upon a large number of our Dutch fellow-colonists. Language is frequently used which seems to imply that the Dutch have some superior right even in this colony to their fellow-citizens of British birth. Thousands of men peaceably disposed and, if left alone, perfectly satisfied with their position as British subjects, are being drawn into disaffection, and there is a corresponding exasperation on the side of the British.

"I can see nothing which will put a stop to this mischievous propaganda but some striking proof of the intention of Her Majesty's Government not to be ousted from its position in South Africa. And the best proof alike of its power and its justice would be to obtain for the Uitlanders in the Transvaal a fair share in the government of the country which owes everything to their exertions. It could be made perfectly clear that our action was not directed against the existence of the Republic. We should only be demanding the re-establishment of rights which now exist in the Orange Free State, and which existed in the Transvaal itself at the time of, and long after, the withdrawal of British sovereignty. It would be no selfish demand, as other Uitlanders besides those of British birth would benefit by it. It is asking for nothing from others which we do not give ourselves. And it would certainly go to the root of the political unrest in South Africa; and though temporarily it might aggravate, it would ultimately extinguish the race feud, which is the great bane of the country."

On receipt of Sir Alfred Milner's message Mr Chamberlain sent, on 10th May, a full and comprehensive despatch dealing both with the Uitlander petition and the message. He concluded by suggesting a conference at Pretoria between the President and the High Commissioner. Meanwhile a proposal had been made, at the instance of some of the Schreiner Ministry, in conjunction with President Steyn of the Free State, for a conference at Bloemfontein. This was accepted. On 31st May the conference began its sittings, and it was very soon evident that Mr Kruger's object was to obtain concessions, not to make them. Sir Alfred Milner practically confined his demands to a five years' franchise, which he hoped would enable the Uitlander to work out his own salvation. It is necessary to point out that even had Sir Alfred Milner's proposition been accepted, the Uitlanders would have been left with a very small representation in the Volksraad. Nevertheless, it was much too advanced a proposal for President Kruger. He had quite other views. His objects were to obtain Swaziland, Zambaansland, a seaport, and an arrangement whereby all future questions which might arise with Great Britain should be settled by arbitration.

Bloemfontein conference.

The conference broke up without any result, and the gulf seemed wider than ever. The two great parties into which South Africa had gradually been divided now made themselves heard all over the larger towns. The Imperialists held enthusiastic meetings, at which confidence in the High Commissioner was expressed. The Bond and Afrikander party openly proclaimed that Kruger had offered considerable concessions, though privately they expostulated with him. Messrs Hofmeyr and Herholt, the one the leader of the Bond and the other the Cape Minister of Agriculture, visited Pretoria to reason with Mr Kruger. They found him deaf to all argument, while the Transvaal Volksraad apparently regarded the whole franchise question as one which they could not be expected seriously to entertain.

In the despatches which followed from Pretoria, considerable confusion was manifest. Whether the obscurity was intentional, or whether it was the outcome of mental confusion on the part of Mr Reitz, whose retirement from the Presidency of the Free State had been caused by mental breakdown, it is impossible to say. But it is at any rate certain that one of the state papers purporting to contain the draft of a new franchise law was so ambiguous that it was supplemented by an explanatory memorandum from the State Attorney, and called forth the severe censure of Sir Henry de Villiers, the Dutch Chief Justice of Cape Colony, who in writing about it observed, "Surely a law should be clear enough to speak for itself, and no government or court of law will be bound by the State Attorney's explanations."

The fact is that all offers of amelioration on the part of the Transvaal, subsequent to the Bloemfontein conference, were as disingenuous as they had always been before. The end was bound to come. The Boers had long before made up their minds to a trial of strength with Great Britain for supremacy in South Africa. The warning of the wiser heads in the Afrikander party was useless. President Kruger, his executive, and a certain section of young Boers had persuaded themselves they could win the day in battle. On 9th October 1899 the Transvaal ultimatum was formally handed to the British Agent at Pretoria.

The Boer ultimatum.

This historic ultimatum was in the form of a somewhat long letter, and concluded by requesting Her Majesty's Government to give it the assurance

"(a) That all points of mutual difference shall be regulated by the friendly course of arbitration, or by whatever amicable way may be agreed upon by this Government with Her Majesty's Government.

"(b) That the troops on the borders of this Republic shall be instantly withdrawn.

"(c) That all reinforcements of troops which have arrived in South Africa since the 1st June 1899 shall be removed from South Africa within a reasonable time, to be agreed upon with this Government, and with a mutual assurance and guarantee on the part of this Government that no attack upon, or hostilities against, any portion of the possessions of the British Government shall be made by the Republic during further negotiations within a period of time to be subsequently agreed upon between the Governments, and this Government will, on compliance therewith, be prepared to withdraw the armed burghers of this Republic from the borders.

"(d) That Her Majesty's troops which are now on the high seas shall not be landed in any port of South Africa.

"This Government must press for an immediate and affirmative answer to these four questions, and earnestly requests Her Majesty's Government to return such an answer before or upon Wednesday, the 11th October 1899, not later than 5 o'clock p.m.; and it desires, further, to add that in the event of unexpectedly no satisfactory answer being received by it within that interval, it will with great regret be compelled to regard the action of Her Majesty's Government as a formal declaration of war, and will not hold itself responsible for the consequences thereof; and that in the event of any further movements of troops taking place within the above-mentioned time in the nearer directions of our borders, this Government will be compelled to regard that also as a formal declaration of war."

This ultimatum was cabled to London, and on the

following day, Mr Chamberlain telegraphed as follows to Sir Alfred Milner:—

"Her Majesty's Government have received with regret the peremptory demands of the Government of the South African Republic conveyed in your telegram of 9th October. You will inform the Government of the South African Republic, in reply, that the conditions demanded by the South African Republic are such as Her Majesty's Government deem it impossible to discuss."

On 11th October the Free State Boers seized a Natal railway train on their borders, and on 12th October, at Kraaipan, within Cape Colony, the first shot of the greatest war in which Great Britain had been engaged for nearly a hundred years was fired. For the course of the war, see under TRANSVAAL.

Recapitulation. The foregoing review of the history of South Africa from the earliest days of European colonization clearly brings out certain facts of the deepest interest. Colonization in the truest sense of the word, since the days of Greece and Rome, was not understood by European nations until the end of the 18th and first half of the 19th centuries. The Portuguese colonies are an instance of what results from merely establishing an official caste to hold some sort of nominal rule over a settlement, without endeavouring to develop a country for the advantage of all its inhabitants. The Cape under the Dutch East India Company was no better. The company ruled as absolute tyrants for one hundred and forty-three years. The so-called "free burghers" had no rights or privileges of any kind. They were little better than slaves of the company, and it was under this system that there grew up the "Trek Boer" class, who wandered like Arabs from one pasture on the frontiers to another. The habit of flying from all government and endeavouring to set up their own laws was thus acquired, and was never abandoned by the Trek Boers and their descendants. These men founded the Free State and Transvaal. If the laudable desire to shape their own destinies had combined with it a due appreciation of the principles of civil liberty and simple justice between man and man, it is probable that a permanent and strong independent Boer state would have grown up in South Africa, which would have become a formidable power. But the vices under which they had suffered when subject to the Dutch East India Company left their mark. Themselves at one time little better than slaves, they now meted out to the natives similar treatment. That they should have been slave-owners when all the rest of Europe was engaged in a similar traffic is no reproach to the Boers. But the humanitarian wave of sentiment which culminated in the abolition of slavery never reached the remote wilds of the colonial frontier. The name of Wilberforce, the cause he championed, the iniquity of traffic in human life—these were things unheard of on the Orange. The native was a hewer of wood and drawer of water provided by God for the service of white men. To the Boers the liberation of slaves in Cape Colony was only one more piece of European tyranny. Thus the Trek continued and the Boer republics were founded. The vacillation in British policy which followed has been referred to. It was deplorable. But whatever errors may have been committed by Colonial Secretaries, Governors, and High Commissioners, republicanism was established and recognized. Faction, strife, anarchy, and bankruptcy under a nominal republic brought about annexation of the Transvaal in 1877. Retrocession of the country by Great Britain in 1881 gave to republicanism another lease of life. Meanwhile mineral discoveries had brought wealth to the Free State, and they now brought it to the Transvaal. In both instances the work which brought about the industrial development of these resources was done by men not of Boer race. With wealth came still higher ambitions. The Republican Boers became divided into two camps. President Brand represented the enlightened division. They recognized the desirability of cordial co-operation with the British, who at least held the ports, constructed railways, chiefly conducted the commerce of the country, and protected the coasts. President Kruger, still cherishing the old ideals of monopoly in all things handed down through generations of trekkers from the Dutch East India Company, led the other division, an exclusive and even retrogressive party. The one hope, the one chance, for Boer republicanism was a reconciliation of these two divisions of Boerdom. The opportunities for such reconciliation were abundant. On at least three occasions after 1881 President Kruger deliberately spurned overtures which would have accomplished this object and have established Boer independence on a constitutional and permanent basis. He rejected President Brand's scheme for federating the two republics in 1887, because the constitution suggested was a liberal and civilized one, much on the lines of the United States. He refused the overtures of the large progressive and enlightened Uitlander section of the Transvaal inhabitants, a numerical majority, which might have been accepted at any time between 1892 and 1895, and which, while securing equal privileges to all white men, would have incorporated a progressive and wealthy element in the state. Such a combination, accepted in a liberal spirit, would have made a powerful republican state. Lastly, with the alternative of a suicidal war clearly before him, he rejected the Milner proposals at the Bloemfontein conference. If, then, republicanism failed in South Africa, the cause of its destruction cannot fairly be said to be the policy of Great Britain. The cause was the endeavour to perpetuate a system of monopoly in politics and commerce as the privilege of a class, a system which covered the Dutch East India Company with reproach and led to its dissolution, which drove the Trek Boers into the wilderness, the Uitlanders into rebellion, and finally drove Great Britain to fight for the establishment of that civil equality, impartial justice, and commercial freedom under British supremacy which Dutch so-called republicanism had refused to grant. The Dutchmen of South Africa adopted as their cry "Africa for the Afrikanders!" This is a cry which no Englishman need resent. But among Afrikanders should obviously, in justice, be included all British and other Europeans who have domiciled themselves in the country.

Law.—The basis of the common law of British South Africa is the Roman-Dutch law as it existed in Holland at the end of the 18th century. This was simply the old Roman jurisprudence embodied in the legislation of Justinian, modified by custom and legislative decrees during the course of the centuries which witnessed the growth of civilization in Europe; and it is to all intents and purposes the jurisprudence which was the foundation of the Code Napoleon. It was in part closely akin to the "modern Roman law" which is practised widely over the continent of Europe, and even in Scotland, at the present day. The authorities upon the common law in South Africa are: the Dutch commentators upon the civil law, the statute law of Holland, the decisions of the Dutch courts, and, failing these, the *corpus juris civilis* itself.

In the century which has elapsed since the establishment of British rule at the Cape the law has been considerably modified and altered, both by legislation and by judicial decisions, and it is not too much to say that at the present time there exists hardly any material difference in principle over the greater part of the field of jurisprudence between the law of England and the law of South Africa. The law of contracts, the law of torts, the

mercantile law, the law relating to shipping and insurance, not to mention other subjects, are practically identical with those of England; and even the criminal law is virtually the same, though the greater elasticity of the civil jurisprudence allows fewer opportunities for the escape of malefactors, notably in cases of fraud or falsity in any form, than exist under the law of England. The constitution of the courts is based on the example of the English judiciary, and the rules of evidence and procedure are practically the same in both criminal and civil cases as in England. All serious cases of crime are tried before a judge and jury, with the same formalities and safeguards as in England, while minor offences are dealt with by stipendiary magistrates possessing a limited statutory jurisdiction. In criminal cases it is necessary for the jury to find a unanimous verdict. In civil cases either party may demand a jury, a privilege which is seldom exercised; but in a civil case the verdict of the majority of jurors prevails.

The most marked difference between the English and South African systems of law is, as might be expected, to be found in the law relating to real property. In South Africa there is a rigid and universal application of the principle of registration. The title to land is registered, in all cases; and so, with a few exceptions, is every servitude or easement, mortgage or charge, upon land. With regard to the devolution of property upon death, it may be remarked that the law of intestate succession applies equally to real and personal estate, there being no law of primogeniture. The rules of distribution in intestacy differ, however, very considerably from those established in England. There is absolute freedom of testamentary disposition in Cape Colony and in some other parts of South Africa. In some of the colonies, however, the old restrictions of the civil law as to the legitimate portion (*legitim*) and kindred matters still obtain, but there is little doubt that these will soon be abolished. The effect of marriage upon the property of the spouses is, by the Roman-Dutch law and in the absence of any ante-nuptial contract to the contrary, to bring about a complete community of property, virtually a universal partnership between husband and wife, subject to the sole and absolute control of the husband while the marriage lasts. The courts have, however, the right to interfere for the protection of the wife in case of any flagrant abuse of the power thus vested in the husband. Ante-nuptial agreements may be of any nature the parties may choose. Such agreements must in all cases be publicly registered. Upon the dissolution of a marriage in community of property, or in the event of a judicial separation *a communione bonorum*, the property of the spouses is divided as upon the liquidation of a partnership. It is not necessary here to refer particularly to certain exceptions to this general rule in cases of divorce.

By the common law gifts between husband and wife during marriage are void as against creditors. This rule cannot be evaded even by ante-nuptial agreement. By the statute law of Natal post-nuptial agreements between spouses are permitted under certain conditions, to which it is not possible now to refer at length. Divorce is granted to either spouse for either adultery or malicious desertion, the distinctions established by the English law between husband and wife in respect of divorce being disregarded.

Language.—The languages spoken in South Africa by the inhabitants of European descent are English and Dutch, the latter chiefly in the form of a patois colloquially known as the Taal. The history of the Dutch language in South Africa is intimately bound up with the history of the South African Dutch people. The basis of the language as spoken to-day is that 17th-century Dutch of Holland which the first settlers brought to the country; and as a matter of fact, although the Dutch of Holland and the Dutch of South Africa differ very widely to-day, Cape Dutch differs less widely from the Dutch language of the 17th century than from the modern Dutch of Holland. The tongue of the vast majority of the Dutch-speaking inhabitants may thus be said to be a degenerate dialect of the 17th-century Dutch of Holland, with a very limited vocabulary. The limiting of the vocabulary is due to two reasons. In the first place, the early settlers were drawn principally from the peasant class, being chiefly discharged soldiers and sailors; and, further, when once settled, the necessity for making the language intelligible to the natives, by whom the settlers were surrounded, led to a still further simplification of speech structure and curtailment of the vocabulary. There thus grew up an ungrammatical dialect of Dutch, suited only to the most ordinary requirements of the everyday life of a rural population. It became a language with neither a syntax nor a literature. At the same time it remained in character almost entirely Dutch, no French—in spite of the incorporation into the population of the Huguenot emigrants—and only a few Malay words, finding a place in the Taal. But side by side with this language of everyday life a purer form of Dutch has continued to exist and find its uses under certain conditions. It must be borne in mind that the Boers of every grade have always been more or less sedulously instructed in religious subjects, at all events to the extent required to fit them for formal membership of their Church, and in all their wanderings they have usually been attended by their pastors. The Dutch Bible and Catechism are written in pure Dutch. The language of the Dutch Bible is as majestic as that of our English version. Moreover, the services of the Church have always been conducted in grammatical though simple Dutch; and the clergy, in their intercourse with the people, have as a general rule abstained from conversing in the ordinary dialect. The Boer thus has but slight difficulty in reading and understanding pure Dutch. Of late years strenuous efforts have been made to teach the language in the schools throughout the greater part of South Africa. In the Transvaal and Orange river republics education was imparted almost exclusively in Dutch. All public business in the Government offices and law courts was conducted in the language, and the Transvaal was being gradually inundated by officials, railway servants, and others introduced from Holland, who spoke modern Dutch.

AUTHORITIES—The reader is referred to the following works which have been consulted, among others, in compiling this article. With reference to the notes on law and language, the writer is much indebted to the Hon. J. W. Leonard, K.C., late Attorney-General of Cape Colony, who has placed his unique knowledge of these subjects at the writer's disposal. E. South Amboy, a borough and seaport of Middlesex county, New Jersey, U.S.A. It is situated in 40° 29′ N., 74° 17′ W., at the head of Raritan Bay, in

the eastern part of the state. Its site is hilly and its plan regular. It is on the Central of New Jersey, the Pennsylvania, and the Raritan River railways. It is an important point for coal shipments, and contains asphalt works, potteries, and other manufactures. Population (1880), 3648; (1900), 6349, of whom 1700 were foreign-born.

Southampton, a seaport and municipal county, (1888), and parliamentary borough of Hampshire, England, a county in itself, at the head of Southampton Water, 79 miles by rail south-west by west of London, on the main line of the London and South-Western Railway. The Itchen, bounding the town on the east, is crossed by the Northam (1889), a free, and a steam floating bridge. The town now consists of 13 wards under a mayor, sheriff, senior and junior bailiffs, 13 aldermen, and 39 councillors. There are 19 churches and many chapels of various denominations; 19 board and 14 National schools. Modern erections include the public library, baths, and the royal pier, reconstructed in 1892. In 1891, 539 persons were engaged in the making of machinery, and 381 in iron and steel manufactures. There are 1 daily, 1 bi-weekly, and 4 weekly newspapers. Since 1892 the docks have been the property of the London and South-Western Railway Company. They accommodate vessels of over 13,000 tons burden, and measure about 250 acres, comprising extensive quays both in the Test and Itchen rivers with 28 feet of water at low water of ordinary spring tides, and 15,000 lineal feet of accommodation; the Empress dock, 18½ acres, with a depth of 26 feet at low water spring tide; the outer dock, 16 acres, with 18 feet at low water spring tide; and the inner dock, 10 acres. There are also two coal barge docks capable of floating 10,000 tons of coal at one time. In all the docks contain about 3 miles of railway line. The five dry docks have from 29 feet to 12 feet depth of water over blocks at neaps. The Prince of Wales, or No. 5 dry dock, opened in 1895, is the largest single dock in the world; it is 750 feet long by 87½ feet wide at sill, and 112 feet at cope level. In 1888 the registered shipping was 322 vessels of 69,431 tons; in 1898, 337 of 123,406 tons. In 1888, 9690 vessels of 1,651,472 tons entered; 9478 of 1,593,780 tons cleared. In 1898, 12,347 vessels of 2,704,390 tons entered; 11,994 of 2,591,441 tons cleared. The value of the imports in 1898 amounted to £12,303,103, against £7,182,734 in 1888. The exports in 1898 were valued at £8,610,265, against £7,407,063 in 1888. The total tonnage of the entrances in 1899 was 4,257,085, of the clearances, 4,220,847. Including coin and bullion, imports were valued at £34,105,645, exports at £19,027,624. Population of municipal and county borough (1881), 60,051; (1891), 65,325. In 1895 it was extended to include, among other districts, Shirley and Freemantle, an urban district with a population in 1891 of 15,898. Extended area, 5295 acres. Population (1891), 82,126; (1901), 104,911. Area of parliamentary borough, 7774 acres. Population (1891), 93,589; (1901), 120,302.

South Australia.—(For geographical and geological features, see Australia.) Each state of Australasia has depended very largely for its prosperity upon the production and export of one or two staple products. What wool has been to New South Wales and gold is to West Australia, wheat has been to South Australia. In 1885 the colony saw the end of a series of seasons eminently favourable to the growth of grain and the production of wool, and to the pastoral industry generally. In the decade 1886 to 1895 there were only two good seasons, and the condition of the state would have been seriously affected were it not for the fortunate mineral discoveries made in Barrier District of New South Wales, the trade of which is commanded by Adelaide. The population in 1860 was 124,112, and the province was third in importance amongst the states forming the Australasian group. In 1870 the population stood at 183,797, and in 1880 at 267,573; in 1890 it was 319,414, and at the census of 1901, 362,604. These figures are inclusive of the population of the Northern Territory, the province of South Australia properly so-called containing 358,508 people and the Northern Territory 4096, the respective density of the two divisions being one person per square mile and one per 128 square miles. The number of males in 1901 was 184,422 and the females 178,182. The births during 1900 numbered 9177 and the deaths 3837, representing 25·59 and 10·70 per thousand of population respectively. The birth-rate has declined very greatly, and births were less numerous in 1900 than in 1880, notwithstanding an increase of about 30 per cent. in the population.

Dividing the years from 1861 to 1900 into five-yearly groups, the following were the average birth-rates:—

Period.	Births per 1000 of Population.	Period.	Births per 1000 of Population.
1861–65. . .	44·14	1881–85 . . .	38·52
1866–70. . .	40·60	1886–90 . . .	34·48
1871–75. . .	37·24	1891–95 . . .	31·24
1876–80. . .	38·28	1896–1900 . .	26·59

Illegitimate births are less frequent in South Australia than elsewhere in Australia; in the five years 1896–1900 the proportion of illegitimate to total births was 3·76 per cent.

The death-rate has always been remarkably light, not having exceeded 13 per 1000 in any year since 1886. The averages for each quinquennial period from 1861 were as follows:—

Period.	Deaths per 1000 of Population.	Period.	Deaths per 1000 of Population.
1861–65. . .	15·70	1881–85 . . .	14·71
1866–70. . .	15·01	1886–90 . . .	12·55
1871–75. . .	15·83	1891–95 . . .	12·08
1876–80. . .	14·90	1896–1900 . .	11·93

The excess of births over deaths in 1900 was 14·89 per 1000, which is in excess of the English experience. In the following quinquennial periods the excess was, 1881–85, 23·81; 1886–90, 21·93; 1891–95, 19·16; and 1896–1900, 14·66 per 1000 inhabitants. This remarkable reduction means a very serious check to the progress of the country, especially as there is very little immigration. The number of marriages celebrated during 1900 was 2313; this represents a marriage-rate of 6·45 and the number of persons married 12·9 per 1000. The number of divorces and judicial separations does not exceed seven a year, and since 1891 their number compared with the marriages in the same period has been as 1 to 300.

The people are mainly of British race; out of 320,000 persons whose birthplace was ascertained at the census of 1891, just over 300,000 were of British or Australian parentage, 11,653 were born on the continent of Europe—of whom 8553 were Germans and 1157 Scandinavians—and 4000 were Chinese. The total foreign-born element of the population numbered only 4·9 per cent. The population increased 16 per cent. between the census of 1891 and the close of 1899; allowing for this increase and adopting the proportion ascertained in 1891, there would be in 1899, 147,400 persons in the province following gainful pursuits, namely, 119,300 males and 28,100 females; the same numbers are got by independent estimates. Agriculture, the main industry, provided employment for 33,430 persons, of whom 32,480 were males and 1030 females. Pastoral pursuits and dairying employed 4640 males and 1540 females, total 6180; and mining employed 5800. The industrial class may be divided into (*a*) persons engaged in manufacturing industries, 16,200 males and 6400 females; (*b*) persons engaged in the construction of buildings, railways, roads, &c., numbering 7900; and (*c*) persons engaged in other industrial pursuits, 12,900; these are chiefly persons whose census description is merely "labourer." The commercial class, including

traders of all kinds as well as persons engaged in finance, numbered 18,900, namely, 16,700 males and 2200 females; while the numbers of persons engaged in transport by sea and land and in effecting communications was 11,800. The professional class comprised 5200 males and 3000 females, or a total of 8200; while the domestic class—comprising persons engaged in providing board and lodging, hotel and restaurant keepers, as well as servants—numbered 16,520, namely, 3550 males and 12,970 females. The foregoing classes show the distribution of employment amongst the 147,400 breadwinners; the remainder of the population, comprising, in 1899, 223,300 persons (75,260 males and 148,040 females), were dependent on the breadwinners, except a small number (1700) who are what is usually termed of independent means. South Australia does not possess any towns of importance besides the metropolis.

Local government. Adelaide was the first Australian city to acquire the right of self-government, and on the 31st October 1840 the first municipal elections in Australia were held in that city. The area of South Australia now under local government embraces 42,493 square miles, the local authorities being called corporations and district councils, according as they control urban or rural areas. Although a large part of the state, properly so-called (337,577 square miles), as well as the whole of the Northern Territory, are without local government, the incorporated area includes all those parts of which the development warrants the right of local government being conferred upon them. Local rates are assessed upon the assumed annual value of the properties liable to be rated, and the amount of such assessed annual value was, in 1900, £2,576,729, and the capital value about 40 millions. The expenditure was £346,081, of which £190,124 was spent on works. The revenue of the various local bodies was £348,768, of which £233,695 was obtained from rates and £115,073 from Government endowment. The total debt of the local bodies at that date was £78,400.

Instruction and religion. The South Australian system of popular education in its present form dates from 1878. It is compulsory, secular, and free. The compulsory ages are over seven and under thirteen years, but children who have attained a certain standard of education are exempt from compulsory attendance. Religious instruction is not allowed to be given in state schools except out of ordinary school hours. Secondary instruction is in the hands of private and denominational establishments, and the University of Adelaide is well endowed and efficient. The state maintained, in 1900, 690 schools, with a gross enrolment of 62,439 pupils, and the average attendance was about 43,100. The sum expended in 1900 on public instruction was £165,706, and of this amount £152,239 was on account of primary instruction. Although education is free, the instruction department has a small revenue; this in 1900 amounted to £11,512, of which £6113 was derived from rents, £3834 from sale of books and school material, and £1565 from fees; the greater portion of the fees comes from the advanced school for girls, which accounted for £1299, the remainder being paid by pupils attending classes in agriculture held in the public schools. The average cost of primary instruction to the state, including cost of school premises and maintenance, is about £3 7s. 4d. per scholar in average attendance. The revenue of the Adelaide University in 1900 was £19,023, of which £6556 was obtained from the Government, £7237 from fees, and £5230 from other sources. The number of students attending lectures during the same year was 465, of whom 238 had matriculated. Technical education is well advanced; the School of Design in Adelaide had 504 students on the roll, and there were branch schools at Port Adelaide and Gawler. The School of Mines and Industries, founded in 1899, had in 1900 an enrolment of 1603 students. Private schools numbered 290, with 860 teachers and 12,322 scholars; the average attendance was about 11,300. Of the teachers, 669 were engaged in general instruction, while 191 were specially engaged in particular subjects. In state and private schools there were 74,761 scholars at all schools and about 54,400 in daily attendance. There were in 1900, 169 public libraries, with 333,000 volumes.

The peculiarity of religion is the strength of the non-Episcopal Churches. The Church of England, which includes over 40 per cent. of the population of the other Australian states, claims only 27 per cent. in South Australia; and the Roman Catholic Church, whose adherents number 22 per cent. in the other colonies, numbers about 14 per cent. in South Australia. The Presbyterian Churches have also less supporters, for only 5·5 per cent. of the population belong to such Churches, compared with 13 per cent. in the other colonies. To the Wesleyan Churches 19 per cent. of the population belong, to the Congregational Churches 3·7 per cent., Baptists 5·5 per cent., Lutherans 7·5 per cent., and other Protestants about 8 per cent.

Finance. For the year ending June 1901 the state had a public revenue of £2,998,231, which is equal to £8 5s. 11d. per inhabitant. This amount includes revenue received by the Commonwealth Government on behalf of the State. The principal sources of public revenue were: import and excise duties, £687,146; land, income, and other taxes, £283,321; railways, £1,254,598; posts and telegraphs, £274,716; public lands, £162,346; and other revenue, £336,104. In 1871 the revenue of the province was £778,000, or £4 4s. 3d. per inhabitant; from that year it rose rapidly until in 1881 it stood at £2,172,000, or £7 16s. 10d. per head; in 1891 it was £2,732,000, or £8 11s. 1d. per head. The expenditure for the year ended 30th June 1901 was as follows: railway working expenses, £747,557; posts and telegraphs, £222,995; public instruction, £156,387; interest and charges of public debt, £1,039,106; and other services, £952,366. The debt charges amount to £2 17s. 11d. per head and absorb 34·5 per cent. of the total revenue of the state. Against this must be placed the net return from services upon which the loan moneys were expended; this amounts to about £634,327, so that the real burden of the province's debt is reduced to £404,779 per annum. On 30th June 1901 the public debt of the state stood at £26,423,805, which is equal to £73 2s. 6d. per head, and the purposes for which the debt was incurred were: railway construction and equipment, £13,332,206; water supply and sewerage, £4,839,140; telegraphs and telephones, £979,758; and other works and services not producing direct revenue, £6,077,613. The debt has tended upwards from the time the state first commenced borrowing, but the largest commitments were between 1878 and 1889, during which period the debt was increased by £15,000,000, and rose from £21 to £66 per head. The amount of the debt in ten-yearly periods commencing with 1861 was:—

Year.	Total Debt.	Debt per Head.
	£	£ s. d.
1861	866,500	6 16 8
1871	2,167,700	11 13 7
1881	11,196,800	39 2 1
1891	20,347,125	62 9 2
1901	26,423,805	73 2 6

South Australia has a large public estate: the area alienated or in process of alienation was 14½ million acres out of a total of 578 million acres, and under lease 265 million acres.

Defence. South Australia, on 31st December 1900, had a small defence force of 3021 men, comprising 2977 partially-paid troops and a paid staff of 44; but in addition to the land force there is a corps of 207 men capable of being employed on local war vessels or as a light artillery land force. The province maintains a twin-screw cruiser of 920 tons, whose armament comprises one 8-inch 12-ton B.L., five 6-inch 4-ton B.L., four 3-pr. Q.F., and five Gatling machine guns, and an auxiliary gun vessel carrying two 6-inch 5-ton B.L. guns. The expenditure of the province on defence in 1900 was £43,649; but this sum includes £10,355 contributed towards the cost of maintaining the auxiliary squadron attached to the Imperial fleet in Australian waters. About a quarter of a million has been expended upon permanent fortifications and charged to the general loans account.

Production. The minerals mined are copper, silver, and gold; and of these, only copper is found in large quantities in the province proper, the bulk of the gold being won in the Northern Territory. The great copper mines at Moonta and Wallaroo are still worked, but the production has greatly fallen off. In 1900 the value of copper raised in the province was £386,015, and the gross production to the end of that year amounted to £22,321,969. Gold to the value of £82,188 was won in 1900, chiefly obtained from the Northern Territory. The value of minerals other than gold and copper won during 1900 was £46,925. In 1871 the mineral production of the colony was valued at £725,000, in 1881 at £421,000, and in 1891 at £365,000, and in 1900 the value was £515,128.

The chief industry is distinctly wheat-growing, and out of 2,369,680 acres under crop in 1901, 1,913,247 acres were under wheat for grain and 341,330 wheat for hay. In some parts of South Australia very fine yields are obtained; but taking it as a whole, the yield of the province is very light. During the ten years 1891–1900 the return per acre varied from a minimum of 1·7 bushels in 1897 to a maximum of 6·1 bushels in 1893. South Australian wheat is of excellent quality and strength, and well known in European markets, to which the province has sent wheat since 1850. There has been little expansion of wheat cultivation since 1880; nor, indeed, has there been any material expansion in the total area under crop. Up to the year mentioned, every season showed an additional area devoted to cultivation; but repeated failure of crops, due to want of seasonable rain, have disheartened farmers, and much land that was formerly cultivated now lies fallow. The following is a statement of the area of wheat harvested for grain at specified intervals from 1861:—

Year.	Acreage under Wheat.	Production.	Average Yield per Acre.
	Acres.	Bushels.	Bushels.
1861 . . .	310,636	63,410,756	11·0
1871 . . .	692,508	3,967,079	5·7
1881 . . .	1,768,781	8,087,032	4·6
1891 . . .	1,552,423	6,436,488	5·6
1899 . . .	1,778,770	8,778,900	4·9
1900 . . .	1,821,137	8,453,135	4·6
1901 . . .	1,913,247	11,253,148	5·9

The total area under crop during the same period was: 1861, 400,717 acres; 1871, 837,730 acres; 1881, 2,156,407 acres; 1891, 1,927,689 acres; and 1901, 2,369,680 acres. In 1901 the principal crops grown, with their acreage, were: wheat 1,913,247 acres, oats 27,988 acres, other grain crops 15,352 acres, hay 341,330 acres, potatoes 6628 acres, vines 20,158 acres, other crops 44,977 acres. In viticulture the province has made considerable progress, and many Germans are employed in the industry. The production of wine for the year 1900 amounted to 1,388,847 gallons, while 2607 cwt. of currants and 8151 cwt. of raisins were also made. The wine made is of excellent quality, and about 400,000 gallons are exported annually to London.

The production of wool has been one of the chief industries since the foundation of the state, but of late years it has been much affected by droughts and low prices, so that the export of locally grown wool in 1901 was considerably less in quantity than in 1880, and little more than half as valuable. In 1861 the colony carried 3,038,000 sheep; in 1871, 4,412,000; in 1881, 6,811,000; in 1891, 7,745,000; and in 1900, 5,283,247. The quantity of wool exported in the year last named was equal to 33,277,660 ℔ weighed in the grease. There was also exported about 9,592,000 ℔ of wool grown in New South Wales. As a cattle-breeding country South Australia does not take a prominent place beside the three eastern states of Australia. The province proper depastured in 1900 only 214,761 cattle, and the Northern Territory about 257,667—in all, 472,428; in 1891 the number was 677,000, and in 1881, 315,000. It was between 1881 and 1891 that the Northern Territory was stocked. The horses in South Australia number about 179,400, and there has been no great increase, for the number in 1881 was 159,678.

Although there are some 30,000 persons engaged in one form or other of manufacturing, only 17,659 are accounted for in the annual statistics of the state; these hands are employed in 1036 establishments. The horse-power employed in the manufactories of the province was 10,794, and in 1900 the value of the plant was estimated at £1,810,000.

Commerce. The tonnage of shipping entering the ports in 1900 was 1,851,803, which is equal to five tons per inhabitant, a very considerable ratio compared with most countries; but this tonnage is quite beyond the requirements of the province, whose trade represents only about 750,000 tons per annum, and is due to the fact that Adelaide is a place of call for all the great lines of steamships trading between Europe and Australia; but when every allowance is made, it will be found that Adelaide is a great shipping centre and the third port of Australasia. The tonnage entering at Adelaide during 1900 was 1,335,442, and the value of imports, £4,739,483, and of exports, £4,363,971. At Port Pirie the value of imports was £405,473, and of exports, £1,566,357; at Wallaroo the imports were £65,052 and the exports £385,881; and at Port Augusta, £5661 and £146,490 respectively. The ports command the greater part of the trade of the Broken Hill and trans-Darling districts of New South Wales, and this trade is very valuable both to the merchants and the railways of the province. The trade at the periods specified was:—

Year.	Imports.	Exports.	Total Trade.	Exports of Domestic Produce.
	£	£	£	£
1861 .	1,976,018	2,032,311	4,008,329	1,838,639
1871 .	2,158,022	3,582,397	5,740,419	3,289,861
1881 .	5,320,549	4,508,754	9,829,303	3,755,781
1891 .	10,051,123	10,642,416	20,693,539	4,810,512
1899 .	6,884,358	8,388,396	15,272,754	3,945,045
1900 .	8,131,782	8,122,100	16,253,882	3,770,983

The great expansion following 1881 was due to the opening up of trade with the western districts of New South Wales. The exports of domestic produce, the value of which is given in the last column, when compared with the other figures in the table, show how greatly the province depends upon its re-export trade. The chief items of trade are bread-stuffs, wool, and minerals; the export of bread-stuffs is very variable, depending so largely upon the rainfall, which in South Australia is extremely uncertain. In 1884 the value of wheat and flour exported was £2,491,896, falling to £633,426 in 1886, and rising again to £2,197,735 in 1888. Since the year last named there have been great fluctuations: in 1898 the export fell to £261,898, and in 1899 it was £785,341, while in 1900 it was £837,642. The value of locally grown wool exported during the twenty-five years ending with 1900 varied between £950,000 and £2,000,000; the value in 1900 was £1,003,391. The value of minerals exported during 1899 amounted to £422,000, and in 1900 to £386,000.

Railways. The first railway was opened in 1856, and connected Adelaide with its port, and the following year saw a line constructed to Gawler, 25 miles from Adelaide. The inability of the Government to borrow money at reasonable rates greatly retarded the construction of railways in the province, and in 1875 there were still less than 200 miles of line: in the next ten years 800 miles were opened for traffic, and in 1901 there were 1736 miles in the province itself and 166 miles in the Northern Territory. There were, in addition, some 14 miles of privately owned lines. The cost of constructing and equipping the state lines stood at £14,326,775 by the middle of the year 1901, and the net earnings £496,142; this represents nearly 3·5 per cent. on the capital invested. The actual interest paid by the state upon its outstanding loans was in the same year nearly 3·8 per cent.: there was therefore a loss of 0·3 per cent. upon the working of the lines; but the state claims that the indirect benefits of railway construction far more than compensate for the direct loss. The gross earnings for the year ended 30th June 1901 were £1,250,461, and the working expenses £754,319; the former represents 5s. 8·3d. and the latter 3s. 5·2d. per train mile. In 1900 the number of passengers carried was 8,498,000 and the goods tonnage 1,628,000. South Australia has two gauges, namely, 508 miles of 5 feet 3 inches and 1393 miles of 3 feet 6 inches line. The line joining Adelaide with the Victorian border, as well as several of the trunk lines, are on the wider gauge.

Post and telegraphs. In 1900 there were 699 post offices, of which 285 were also telegraph stations. The business transacted was: letters and postcards transmitted 20,387,301, newspapers 9,956,351, packets 1,386,624, and telegrams 1,207,288. The total revenue from these services for the year 1900–1901 was £181,350, and the expenditure £148,277; in these sums are included the telephone revenue and expenditure, the former amounting to about £16,000. These sums are exclusive of revenue received by the Commonwealth Government. The use of telephones in Adelaide is rapidly extending; in 1900 there were 8 exchanges and 1558 telephones. There were 5742 miles of telegraph line in operation in 1900, and the state owns the principal overland line by which communication with Europe and the East is maintained.

Banking. The assets of all the banks of issue trading in South Australia on 30th June 1901 amounted to £6,567,776, and the liabilities to £6,747,644; these latter comprised deposits at call £2,608,269, deposits at interest £3,662,127, making a total of £6,270,396; notes and bills in circulation £424,487; and other liabilities £52,761. Amongst the assets were coin and bullion, £1,657,972. The South Australian people are very thrifty, and thirty-one in every hundred have accounts with the savings banks. On 30th June 1901 the deposits numbered 111,537, and the amount to the credit of depositors £3,782,575, a sum equal to £33 18s. 3d. per depositor. Taking deposits in banks of issue and in savings banks together, the total was £10,052,971, which is equal to £27 14s. 6d. per inhabitant. The figures for 1900–1901 show an increase on the total amount of deposits with banks operating in the state; in 1891 the total was £9,992,338, which is £60,000 less than the figures for 1900–1901. The figures of the people's banks are a better guide to the progress of savings than are the banks of issue, which have been accustomed to solicit deposits in England and elsewhere. In 1871 the savings banks held £517,000 on deposit; in 1881, £1,288,450; in 1891, £2,217,419; and on 30th June 1901, £3,782,575.

RECENT HISTORY.

Political developments. The political and social developments in South Australia have been in harmony with the far-sighted Liberalism which attended the infancy of the state. On the attainment of autonomy Governor MacDonnell, in closing the last session of the then partially nominated legislature, made use of the following words:—"I confidently expect that the extended political power entrusted to the people of this country, and the universal suffrage conceded by the new constitution, will prove in reality a safe and conservative measure; and whilst conferring the utmost possible power of self-government, will render stronger and more enduring than ever the cherished ties of affection and loyalty which link this province to the throne of our respected and beloved Sovereign." Judged from every standpoint, this prediction appears to have been amply verified: South Australia deservedly enjoys the reputation of being one of the most progressive and at the same time one of the most stable of existing communities. From its origin as the venture of private enterprise, the state has passed through orderly stages of evolution up to the zenith of democratic government. Such alterations as have been made in the constitution have been in the direction of a still further enlargement of the franchise; for it is recognized that, in a young country of unexplored capacity and unfathomed resources, the ever-varying public problems are most likely to reach a satisfactory solution when, by means of a wide enfranchisement, the activity and intelligence of the whole community are brought to bear upon each question. Payment of members proved to be the corollary of manhood suffrage. It was held that an unrestricted right of selection was unavailing if the area of selection was limited to the few who had been specially favoured by fortune. In 1887 a temporary Act was passed for the payment of £200 a year to each member of both Houses, and in 1890 the law was made permanent. Thus was rendered possible the direct representation of all classes. Soon afterwards the parliamentary labour party came into existence; this forms a considerable proportion of the membership of both Houses, and includes in its ranks men of the highest intelligence, industry, and eloquence. In 1894 the principle of "one man one vote" was extended to that of "one adult one vote" by the inclusion of women as voters on terms of absolute equality with men. There is no bar to the election of women to Parliament whenever the electors think fit to be só represented. The delegates to the Federal Convention and to the Commonwealth Parliament were in South Australia elected by the combined vote of men and women. Elections were formerly held in successive batches, but since 1893 they have taken place simultaneously in all the districts. Electoral expenses are rigidly limited, both as to objects and amount, and a declaration of money thus expended has to be filed by every candidate. Experience has demonstrated that, owing to the intrusion of the personal element, general elections have often failed to afford conclusive evidence of the state of the popular will. Attention has therefore been directed towards the referendum as a means of obtaining an unquestionable verdict on important public issues. Although no general statute had been formulated on the subject up to 1902, custom has definitely established the practice. In 1896, at the general elections, the following questions were submitted to the electors:—"Do you favour (1) the continuance of the present system of education in the state schools? (2) the introduction of scriptural instruction in the state schools during school hours? (3) the payment of a capitation grant to denominational schools for secular results?" An overwhelming majority pronounced in favour of (1) and against (2) and (3). Again, in 1899, a direct vote was similarly taken on the question of household franchise for the Legislative Council. Undoubtedly the practical application of the referendum in South Australia facilitated the adoption of this principle in the ratification and in the method of amendment of the Commonwealth Constitution. The right of the Second Chamber to suggest amendments to Bills which it has not power to amend was borrowed by the Commonwealth from the Constitution of South Australia, as also was the idea of a simultaneous dissolution of both Houses as a means of overcoming possible deadlocks between the Chambers. As one among many improvements in parliamentary procedure may be mentioned the practice of permitting Bills lapsed owing to prorogation to be replaced on the notice paper in the ensuing session by motion without debate.

Finance. The facile but unsound method of meeting a large proportion of the current expenditure out of the proceeds of land sales has long ceased to exist in South Australia. In 1884 a land and income taxation Act was passed, and in 1894 these taxes were made progressive. The land tax is ½d. in the £ on unimproved land values without exemption, with an addition of another ½d. in the £ on land values owned by any individual in excess of £5000. An increase of 20 per cent. on the tax is levied on land held by absentees. There is an exemption of £200 on all incomes. The rate on the taxable income derived from personal exertion is 4½d. in the £ up to £800, and 6d. in the £ for every pound of income in excess of that amount. On incomes derived from property the rates are double, namely, 9d. and 1s. respectively. The death duties are also graduated, and are payable not on the total estate bequeathed, but on the amount received by each beneficiary; the rates range up to 10 per cent. on amounts of £200,000 and upwards. Stamp duties were imposed in 1886. In 1901 South Australian securities were made trustee stocks for British investors.

Crown lands. In partially settled countries such as South Australia the Crown lands policy rivals finance in engrossing the attention of the legislature, but as time goes on the relative importance of these subjects varies in inverse ratio. The earlier budgets, compared with those of later years, when the country had become more fully developed, might be said to resemble the finances of the nursery, whereas the initial alienations of land, comprising the most central and most valuable blocks, necessarily surpassed later transactions in significance. Many phases of public opinion as to the method of disposing of the Crown lands have been witnessed. A general review indicates clearly that the change has been uniformly in the direction of removing impediments and increasing facilities for the settlement of the people either as freeholders or state tenants, on the land. Under the auction system the land was allotted to the highest bidder, with the result that the payment of the purchase-money frequently exhausted the resources of the settler, and subsequent relief had to be afforded by relaxation of the conditions of the agreement to purchase. Eventually land boards were created to allot selections to applicants at low rates and deferred purchase. Perpetual leases are now taking the place of absolute alienation. The tenure is equally good for all purposes of the *bonâ fide* settler, and capital which would otherwise be sunk in acquiring the freehold is set free for making improvements, purchasing machinery, and the manifold requirements of efficient husbandry. Small blocks of 20 acres, or not exceeding £100 of unimproved value, can be obtained by working men in the vicinity of towns, thus on the one hand affording the necessary supply of agricultural labour during the busy seasons, and on the other hand providing a homestead which the holder can with advantage cultivate at slack times when unemployed. Provision was made, under the Closer Settlement Act of 1897, for the repurchase of large estates for agricultural purposes; these lands are leased to farmers at an average rent of about 4½ per cent. on the value. The industry of wheat-growing has received an impetus through the system of drilling in a small quantity of phosphatic manure with the seed. By this means exhausted lands have been restored almost to primitive

fertility. Vine-growing has now become one of the staple industries, and, owing to stringent precautions, the state remains free from the scourge of phylloxera. The great bulk of the unalienated land of South Australia is held in huge areas by Crown tenants, known as squatters, under pastoral leases, which now have a currency of 42 years, with security of tenure. In 1893, when the unemployed were very numerous, the Government established co-operative village settlements on tracts of land adjoining the river Murray. Seven of these are now in existence as irrigation colonies. The water is raised from the river by rotary pumps, and distributed by means of channels, after the plan adopted at Renmark. By the application of water to the adjacent sun-steeped soil, miles of worthless mallee scrub have been converted into vistas of vineyards, orange groves, and orchards. The paramount importance of water supply and conservation has received ever-increasing recognition. The Beetaloo reservoir has a capacity of 800,000,000 gallons, and from its 695 miles of trunk mains a district of over one million acres is reticulated. The supply of Adelaide and its vicinity has been reinforced by a reservoir at Happy Valley, having a contour of about 7½ miles at high-water mark, and containing 2,950,000,000 gallons. The reservoir was formed by the construction of an earthen embankment 2645 feet long and 72 feet high; this is filled from the Onkaparinga river through half a mile of steel main 6 feet in diameter and 3½ miles of tunnel. Works on a large scale have also been constructed at Bundaleer and Barossa. The custom for many years past has been to construct these and other great public works departmentally instead of by contract. Many artesian wells have been sunk on the routes for travelling stock in the interior. The bores of some of these exceed 3000 feet in depth, and the supply varies from 200,000 to 1,000,000 gallons a day. Around some of these wells in the far north plantations of date palms have yielded excellent results.

Agriculture and water.

South Australia was founded when the tide of the *laissez faire* régime was running high, and a patriotic bias in the customs tariff was regarded as an unwarrantable restriction; it is therefore not surprising that free trade should at the outset have received many adherents. There were not wanting, however, some who saw clearly that a country almost entirely occupied in primary production would prove but a barren field for the cultivation of the many-sided activity necessary to a complete national life. It was also maintained that if inducements were given to capital to embark in home industries, a cheapening of the product, due to approximation of supply and demand, would ensue. In accordance with these views, a protective tariff was adopted in 1885. Two years later the duties were increased and extended. The establishment of manufactures and new industries opened a career for youths of inventive and mechanical aptitude, and in several instances the predicted reduction in price of the protected article has been strikingly manifested.

One of the most notable developments in public policy consisted in the extension of the sphere of the state so as to embrace activities formerly considered to be solely within the province of private enterprise. Railways from the outset have been Government undertakings, so also have been water-works of any degree of magnitude; telegraphs and telephones, taken over by the Commonwealth, have always been regarded as state monopolies. A public trustee undertakes, when desired, the administration of estates. In 1895 a state bank was established to provide farmers with the necessary working capital at lowest current rates of interest. A state produce depôt was also organized at the same time to assist farmers in placing their produce to the best advantage on the world's markets. Produce is received by the Department of Agriculture, prepared for shipment, certified as to quality, and graded. Small parcels from a number of producers are grouped together in one consignment and shipped at the lowest rates. The Government of South Australia also undertakes, if so desired, to act as agent in London for the consignor, and to arrange for the sale of his produce; so that a farmer who has no representative at the port of destination, but is desirous of ascertaining whether a profitable trade can be established in any class of produce, has only to send the goods to the depôt, and await the arrival of a cheque when the account sales come to hand. An advance amounting to three-fifths of the value of the produce at 5 per cent. is made if desired. Wine shipped through the produce depôt is analysed and examined in bulk by Government experts, and if found to be both sound and pure, is sent to the bonded depôt in London with a certificate to that effect: this is recorded on the label of the bottles in which it is retailed, under the name of the "Orion" brand. Cyanide works have been erected in various centres for treating ore raised by miners working in the neighbourhood. State smelters for copper ore have been built at Port Augusta, but are not now in operation. There is a Factory Act permitting the establishment of wages boards, and also legislation providing for a weekly half-holiday and the early closing of shops. A compulsory conciliation Act deals with the prevention and settlement of industrial disputes. The Right Hon. C. C. Kingston was the pioneer in Australasia of legislation of this description. These measures were at first denounced by some as Socialistic, and were regarded by many as an undue interference with private enterprise. Some of the state aids were, however, speedily recognized as affording additional incentives to industry, and by enabling producers and workers to obtain a better return for their labour, may fairly be held to have assisted rather than to have retarded private enterprise. In 1893 a bonus on butter exported to the world's markets was successful in bringing into existence a fully equipped export trade. Public opinion in South Australia has little tolerance with laxity. Children are prevented from selling articles in the streets after 8 P.M., and are not allowed to fetch beer from public-houses. The age of consent has been raised to 17 years. The notification by medical men of cases of pulmonary tuberculosis to the local authorities is compulsory.

Government enterprise.

No pains have been spared to keep pace with modern improvements in popular education as an indispensable feature in democracy. South Australia holds in reverent and loving memory the name of John Anderson Hartley, the originator of the state school system, who died in 1896, and to whose character as a man and genius as an organizer the schools of South Australia will remain as a perennial monument. School fees for children under the compulsory age of 13 were abolished in 1891, and in 1898 the older children were also admitted free. Students in training have now the advantage of a two-years' course at the university. Technical education has received much attention. A foundation was long ago laid in the primary schools by the inclusion of drawing as a compulsory subject, and by affording facilities for manual training. In 1889 the South Australian School of Mines and Industries was established, and under the presidency of Sir Langdon Bonython has proved a most valuable institution. Other technical schools are in operation in industrial and mining centres. A reserve of two acres is attached to all new country schools, and systematic lessons in practical agriculture are given by many teachers. In order to encourage tree-planting, a yearly school holiday devoted to this purpose, and known as Arbor Day, was established in 1886. With a similar object, the state has distributed, free of charge, 5,000,000 forest trees to 21,000 persons. Over 1,250,000 vines have also been given away. The boys' field club, with the motto "The naturalist loves life," has since 1887, under the direction of Mr W. C. Grasby, been one of the pioneers of nature-study. A state secondary school for girls has been for many years self-supporting, and in 1897 secondary agricultural schools for boys were organized in Adelaide and other centres. Half the school hours of each day are spent in the class-room, the remainder being devoted to workshop, field, and laboratory practice. An agricultural college at Roseworthy, 25 miles north of Adelaide, imparts a high-class theoretical and practical training in the various branches of agriculture, including viticulture and wine-making. The fee charged is £30 a year, including board and lodging. Information as to practical and scientific husbandry is disseminated among the farmers by means of an Agricultural Bureau, with numerous branches throughout the country. A journal is published conjointly by the departments of agriculture and industry, containing reports of the proceedings of the bureaus, and articles by Government experts, together with industrial topics and matters of interest to artisans, and also particulars furnished by the Labour Bureau as to prospects of employment in various districts.

Education.

South Australia played a conspicuous part in the attainment of Australian Federation. The popularly-elected Convention which framed the Commonwealth Constitution Act, held in 1897 its first session in Adelaide. The Right Hon. C. C. Kingston, then Premier of South Australia, afterwards Minister for Trade and Customs in the Commonwealth, was elected president of the Convention, which subsequently met both in Sydney and Melbourne. South Australia was the first of the colonies to submit the Federal Bill to the referendum, and to pass the address to the Sovereign praying that Imperial assent might be accorded to the measure. Mr Kingston was one of the delegates who watched the passage of the Act through the British Parliament. When the Commonwealth Parliament was constituted, and the Hon. Sir Richard Baker, K.C.M.G., president of the South Australian Legislative Council, and the Hon. Sir Frederick Holder, K.C.M.G., leader of the South Australian House of Assembly, were respectively elected President and Speaker of the Federal Senate and House of Representatives. South Australia was also the first Australian state to make the necessary adjustments in the local legislature consequent on some of its most important functions being taken over by the Federal authority. The number of members of the Legislative Council has been reduced from twenty-four to eighteen, and of the Assembly from fifty-four to forty-two, and there are now four ministers in place of the previous six.

Federation.

The existence of South Australia as a colony was coterminous with the reign of Queen Victoria. The colony was established only a few months before the accession of that monarch, and South Australia ceased to be a colony by entering the Commonwealth as a state within a few days of the close of the Victorian Age. (J. A. CO.)

South Bend, a city of Indiana, U.S.A., capital of St Joseph county. It is situated in 41° 39′ N. and 86° 12′ W., on St Joseph river, in the northern part of the state, at an altitude of 725 feet. It has five railways, the Grand Trunk, the Illinois and Iowa (including the St Joseph, South Bend, and Southern), the Lake Shore and Michigan Southern, the Michigan Central, and the Vandalia. It is an active manufacturing place; in 1900 there were 302 establishments, with a total capital of $18,156,638. They employed 8257 hands, and the product was valued at $14,236,331. The two principal articles of manufacture were agricultural implements, with a value of $2,432,083, and carriages and waggons, value $3,494,052. The assessed valuation of real and personal property was, in 1899, $15,047,350, the net debt only $918,238, and the rate of taxation $24.50 per $1000. Population (1890), 21,819; (1900), 35,999, of whom 8601 were foreign-born and 572 negroes. Of 10,402 males 21 years of age and over, 536 were illiterate (could not write).

South Bethlehem, a borough of Northampton county, Pennsylvania, U.S.A. It is situated in 40° 37′ N. and 75° 23′ W., on the south bank of the river Lehigh, in the eastern part of the state. It is on three railways, the Central of New Jersey, the Lehigh Valley, and the Philadelphia and Reading. The site of the borough is hilly; it has an excellent water-supply and sewerage. It is the seat of the famous iron-works of the Bethlehem Iron Company, with its furnaces, rolling mills, ordnance shops, and armour-plate works. Besides these it has brass and zinc works and other manufactures. It is the seat of Lehigh University, a non-sectarian institution, opened in 1866, which had in 1899 a faculty of 42 and was attended by 325 students. Population (1890), 10,302; (1900), 13,241.

Southbridge, a town of Worcester county, Massachusetts, U.S.A. It is in the southern part of the state, bordering on Connecticut. The town has an area of 21 square miles, and contains a village bearing the same name, located on Quinebaug river and on a line of the New York, New Haven, and Hartford Railroad, at an altitude of 500 feet. It has a variety of manufactures. Population (1890), 7655; (1900), 10,025, of whom 3468 were foreign-born.

South Carolina, one of the original thirteen states of the American Union, situated on the southern Atlantic coast between North Carolina and Georgia. It was founded under royal charters of Charles II. of 1663–1665. The state was peopled first by a colony from England by way of Barbados, followed by others of Dutch from New York, Huguenots from France, Scots, Irish, and Scots-Irish, Germans, and Welsh. The colony was planted as an outpost to assert the right of Great Britain to disputed territory, and so was warred upon by Spain and France, and suffered from Indian incursions instigated by those Powers. This circumstance, and her great distance from the other colonies, led to the development of the peculiar characteristics for which the state has been noted. The great staples of rice and indigo, cultivated upon a rich virgin soil by negro slave labour, produced great wealth, in the enjoyment of which a closer intercourse with the mother country was maintained than that of other colonies: her young men were sent to the universities abroad for their education, and a highly-educated, cultured, and refined society was thus formed. In consequence of the close ties to England, there was great opposition in South Carolina to the American Revolution. Her people were divided upon the subject, and yet it was upon her soil that the last three years of that struggle were waged, and in it she suffered more than any other state. Within her borders no fewer than 137 battles or affairs, great and small, were fought. Much of the history of the United States turns upon that of this little state. She led in both the Nullification and Secession movements. Three times has the city of Charleston been besieged, *i.e.*, by the Spaniards and French in 1706, by the British in 1780, and by the Union forces in 1861–65. Her harbour is celebrated for the victory of Fort Moultrie over the British fleet and army in 1776; for the battle of Fort Sumter on the 12th–13th April 1861, which precipitated the war between the states; and for the defence of that fortress by the Confederate army during the years 1863–65. With a white population of but 291,300, and only 55,046 arms-bearing men, in the first year of the war she put in the field 44,000 volunteers, and during its existence 62,838 effective men, with an enrolment, including reserves, of 71,083, of whom 22 per cent. were killed in the field or died of disease or in prison. The state suffered so terribly after the war, under the iniquitous rule of the Reconstruction Government, as to be known as "the prostrate state." Her recovery since has been wonderful.

Population.—The population in 1880 was 995,577; in 1890, 1,151,149, an increase of 155,572, or 15·6 per cent.; and in 1900, 1,340,316, an increase of 189,167, or 16·4 per cent. The total land surface of the state is approximately 30,170 square miles, and the average number of persons to the square mile has increased from 38·2 in 1890 to 44·4 in 1900. In 1900 there were 16 incorporated towns and cities which had each a population of more than 2000 and less than 5000, 4 more than 5000 and less than 10,000, and 4 more than 10,000, namely, Charleston (55,807), Columbia (21,108), Greenville (11,860), and Spartanburg (11,395). The population of Charleston increased during the decade from 1890 to 1900 only 1·6 per cent. Of the population in 1900, 664,895 were males and 675,421 females; 1,334,788 were native-born and 5528 foreign-born; 557,807 were whites, 782,321 negroes, 67 Chinese, and 121 Indians. Of the white male population of 21 years or over, numbering 130,375, 15,865, or 12·2 per cent., were illiterate; of the corresponding negro population, numbering 152,860, 83,618, or 54·7 per cent., were illiterate.

Finance.—When the first governor under the Reconstruction Act was inaugurated in 1868, the actual debt of the state was a little less than $5,800,000. In five years a legislature but few members of which were taxpayers, and those only to a nominal amount, had increased this to a sum estimated at $33,900,000. Fortunately for the taxpayers, these legislators were obliged themselves to repudiate a large part of this indebtedness. In 1876 the Democratic party rose, under the lead of Wade Hampton, and overthrew the carpet-bag rule, as it was called. One of the first measures of the restored government was the appointment in 1877 of a commission to investigate the debt of the state. Under this commission the total valid indebtedness was fixed at $6,406,606, which was funded in 1894 in bonds bearing interest at the rate of 4½ per cent.

Election Legislation and the Negro Vote.—In order to restrict the ignorant negro vote, under which it was impossible to maintain a decent government, the General Assembly in 1882 instituted an electoral system which enforces an educational qualification by requiring the voter (who is secluded) to select his ticket himself and deposit it in the appropriate box. The system has become known as the "Eight-Box" system, and has been imitated in other states. In 1895 a convention framed a new state constitution, differing from the old in many important particulars. The qualifications for suffrage were extended. From the adoption of the constitution in 1895 to 1st January 1898 it was made necessary for the voter to understand and explain any section in the constitution when read by the registration officer; but since that day persons applying for registration are required (*a*) to read and write any section of the constitution submitted to them, or (*b*) to show that they own property in the state assessed at $300 or more, and have paid all taxes collectable during the previous year. At the same time a system of registration, which is peculiar to South Carolina, was incorporated in the constitution. Registration is not, as elsewhere, repeated before each election, but is renewed only once in every ten years. Upon a given day in every month, however, persons coming of age, or otherwise becoming entitled to vote, may have themselves enrolled. When a voter enrolls, he is given a certificate, which he is required to present when voting, for comparison with the entry in an official book. This system was adopted to meet

the difficulty of identifying the negro by the features of the face, whose surname, adopted at random upon emancipation, is often repeatedly changed, and whose nomadic habits since emancipation permit no identification by residence. The system, of course, applies to all electors, white or black.

Dispensary Liquor System.—During the existence of slavery the negroes were little used to the intoxicating effect of liquor, but after their emancipation every cross-road soon had its saloon or travelling liquor waggon, and in consequence their riotous conduct threatened the peace and safety of rural communities. This led to the prohibition of the sale of liquor outside incorporated towns, where the sale was under police regulation. Meanwhile a general prohibition agitation was carried on, which resulted in the adoption of local prohibition laws in many towns and cities, and finally in the present dispensary system. This system is based upon that of Gothenburg, though not identical with it. By it the state becomes the sole dispenser, and undertakes to furnish to purchasers chemically pure liquors in packages of not less than one-half pint, securely sealed, the package not to be opened nor the liquor to be drunk on the premises of the dispenser. The profits are appropriated to state, county, and municipal purposes, that which goes to the state being devoted to education. To carry on the system a vast machinery of officers, state and county boards, and dispensers is provided, which has opened the way to corruption and extravagance. Heretofore a large constabulary force has been employed, and the enforcement of the system has caused bitterness, strife, and bloodshed. As a vendor of liquor the state becomes interested in the profits, and has practically forced dispensaries upon localities in which absolute prohibition previously obtained. The system is now as much opposed by prohibitionists as by those who are against any interference with the business of liquor-selling beyond the necessary police regulation. It must be said, however, that the rigid enforcement of its prohibitory features has so completely broken up the city saloons and the cross-roads liquor dealers as to reconcile many citizens and planters who are opposed to the system on general grounds. The Constitutional Convention of 1895 incorporated a prohibition of the saloon system into the constitution.

The Supreme Court.—The Constitutional Convention of 1895 provided also that the Supreme Court shall consist of four members instead of three, *i.e.*, a chief justice and three associate justices, the concurrence of a majority of whom is necessary to reverse on appeal, thus giving weight to the circuit decision appealed from, and securing a clear preponderance of legal opinion in the decision of any question. It also extended the length of the terms of the justices of the Supreme Court to eight years, and so classified its members that the term of one of them expires every two years. It gives to the Supreme Court power to call in all the circuit judges of the state to sit *in banc* with them in certain cases.

Divorce.—By virtue of an unwritten law of the state, divorces have never been granted, except during the Reconstruction period. The Convention of 1895 ordained that "divorce from the bonds of matrimony shall not be allowed in the state."

Manufactures.—In 1860 South Carolina raised her largest crop of cotton up to that time—to wit, 350,000 bales of upland cotton. It was believed then that cotton could not be raised without slave labour. In 1898–99 the crop was 1,040,000 bales, of which 400,000 bales were spun in South Carolina. In other words, the state spun more cotton of her own growth than she had raised in the year 1860, and had still for export a crop 26 per cent. larger than the whole of that of 1860. One of the happiest results of this development is that the poor white—forced away from the farms by competition of negro cheap labour—finds a haven in the cotton-mills villages. A family the limit of whose income was from $100 to $150 dollars a year gets at the mills from $70 to $80 per month, paid in some cases every two weeks, with entire liberty to trade at their own pleasure. The best managed of these mills have free schools, open ten months in the year, with churches and reading-rooms. The following table illustrates the extraordinary recent increase of cotton mills:—

Year.	Mills.	Capital.	Spindles.	Looms.	Employés.
1820 .	1	...	588	...	...
1840 .	15	$617,500	16,400	200	600
1850 .	18	857,200	20,000	300	1,000
1860 .	17	827,825	16,461	931	900
1870 .	12	1,337,000	34,940	745	1,100
1880 .	14	2,776,100	82,334	1,676	2,100
1890 .	34	11,141,833	334,476	8,546	8,200
1899 .	105	45,000,000	1,906,000	53,351	45,000
1902 .	109	...	1,931,900	54,535	...

The following table shows the condition of the manufacturing and mechanical industries in 1890 and 1900:—

	1890.	1900.	Per cent. of Increase. 1890–1900.
Number of establishments . . .	2,382	3,762	57·9
Capital . . .	$29,276,261	$67,356,465	130·1
Wage-earners . .	22,748	48,135	111·6
Value of product .	$31,926,681	$58,748,731	84·0

The value of the manufactures of cotton goods was $29,723,919 in 1900 as compared with $9,800,798 in 1890. Lumber timber products rose from $2,146,750 in 1890 to $5,207,184 in 1900.

Tobacco.—So recently as the middle of the 'eighties, not one pound of tobacco was planted in South Carolina. According to the best estimates, there were sold in 1899 in the various markets of the state 25,500,000 ℔, and shipped from the state 8,000,000 ℔, making a total of tobacco raised in the state 33,500,000 ℔. The average yield per acre is 770 ℔, the total acreage about 44,000. The crop averages 8 to 10 cents per ℔. The crop of 1899 was valued at $2,680,000. South Carolina is now the second state to North Carolina as a producer of "bright tobacco," the whole of her crop being of that description.

The "Pinehurst" Tea Experiment.—The "Pinehurst" tea experiments, begun about 1890 by Professor Charles U. Shepard, M.D., and latterly assisted pecuniarily by the U.S. Department of Agriculture, bid fair to result in the creation of a new industry. The experiments have been conducted with many varieties of seed and under different conditions of soil, and over 50 acres have been planted. To reduce the cost of labour for plucking tea-leaf, which was inordinately high as compared with the Orient, a free school was built where negro children are taught the ordinary branches, earning the money to buy food and clothing by picking tea. The yield of (dry) tea has been as follows: 1894, 83·8 ℔; 1895, 185·7 ℔; 1896, 215 ℔; 1897, 247·5 ℔; 1898, 307·3 ℔; 1899 to 15th September, 496·1 ℔. It has been shown that the yield per acre approximates that in the countries from which the plants were imported.

Phosphate.—From 1867 to 1890 the state produced enough phosphate rock to fix prices for all other varieties, and to control both foreign and domestic markets. This monopoly was ended by the discovery of phosphate rock in Florida and Tennessee. South Carolina now produces about 500,000 tons annually, Tennessee about the same, and Florida as much as both of these. In the manufacture of fertilizers, established on the basis of her phosphate rock, the state still holds her prestige. Factories in the state can manufacture 475,000 tons of fertilizer, representing a business on manufactured goods of about $5,000,000, to which should be added $300,000 for raw materials furnished in connexion with manufactured fertilizers. The state probably manufactures and sells more fertilizers than any other in the Union, and it is believed that the city of Charleston is the largest manufacturing centre of this class of goods in the world.

Education.—One of the reasons urged for calling the Constitutional Convention of 1895 was that the school tax of two mills prescribed in the constitution of 1868 should be eliminated, as the constitution was not the place for a tax levy; the sentiment of the convention for the advancement of education was, however, so strong that the prescribed tax was not only retained, but was increased from two mills to three mills. In addition to the collegiate institutions of the state previously established, to wit, the South Carolina College at Columbia and the State Military Academy in Charleston, in 1889 the state established the Clemson Agricultural College of South Carolina at Clemson, Anderson county, S.C., in which there are three full courses of study: agricultural, mechanical, and textile. In 1895 it established the Winthrop Normal and Industrial College (female) at Rock Hill, which during the first three years of its existence received 800 students. In 1900 there were 50 graded schools in the state, the term "graded" being applied to all schools in towns which have a special tax levied for their support.

(E. McC.)

South Dakota, one of the north-western states of the American Union, about 360 miles long, with an average width of about 225 miles; it contains 77,850 square miles.

Geography and Geology.—The surface of the state, with the exception of the Black Hills in the south-west corner, is generally rolling prairie. The land east of the Missouri river is fertile and well adapted to agriculture, that west of the river is drier, more broken, and well suited to stock-raising. No timber is found in the state outside the Black Hills, except along the banks of the rivers and streams. The Black Hills, where the timber has not been cut off, are covered with pine. The timber along the rivers and streams is ash, elm, cotton-wood, and box elder. Oak and black walnut are also found. The greater portion of the state is of Cretaceous formation, with some Tertiary deposits in the southern part. The Black Hills are a distinct formation. Discoveries are constantly being made of gold and silver in this part of the state. In 1899, 312,962 ounces of fine gold and 145,600 ounces of silver were mined; and mines of mica, gypsum, and bituminous coal of good quality have been also opened and developed. Natural gas has been discovered in different parts of the state, especially in Hughes, Sully, and McCook counties, and is being utilized to some extent for heating and illuminating. Quartzite sandstone and other kinds of building rock are found in abundance in various parts of the state. In 1899, 50,000 barrels of very excellent cement, equal in strength and endurance to the best Portland cement, were manufactured at Yankton from the chalk rock and clays found in abundance along the bluffs of the Missouri river.

Agriculture.—Of the agricultural products, wheat is the staple crop, and has a world-wide reputation as producing the best of flour; 41,889,380 bushels were grown in 1899, valued at $20,957,917. The yield of corn in the southern part of the state and on the Missouri bottom lands frequently averages 75 bushels to the acre; 32,402,540 bushels were grown in 1899, valued at $7,263,127. Of oats, 19,412,490 bushels were grown, valued at $4,114,456. Flax, barley, peas, beans, hay, and other farm products are grown everywhere in the state. The grasses on the ranges are very nutritious. Timothy, alfalfa, and other grasses are cultivated successfully east of the Missouri river. Some failures of crops have resulted from drought in the northern and north-western portions of the state. An artesian basin has been developed in the central portion of the state at a depth of from 500 to 1100 feet, which is being utilized for irrigation, and in some localities for manufacturing. Though there is a period of low temperature during midwinter, the climate is dry and bracing.

Education and Charities.—There were in 1898, 3582 common schools, with 4322 teachers and a total attendance of 77,516. The children of school age (between 6 and 20 years) numbered 96,134, and the expenditure on common schools for that year amounted to $1,729,462. According to the census of 1900, the number of persons between 5 and 20 years of age inclusive in that year was 147,165. The percentage of illiterates is very small. Out of 112,681 males of voting age in 1900, 5442 (4·8 per cent.) were unable to write; of these, 2234 were of foreign birth. The State University at Vermilion had 384 students for the year 1900, and has 28 instructors. It is under the control and management of the state. There are also normal schools at Madison, Spearfish, Springfield, and Aberdeen; an agricultural college at Brookings; a school of mines at Rapid City; and a school for deaf mutes at Sioux Falls. These have a total of 1420 students and 63 instructors. There are several excellent denominational schools and colleges. The state penitentiary is at Sioux Falls, the insane asylum at Yankton; there is a reform school at Plankinton, and a soldiers' home at Hot Springs.

Railways.—In 1898 there were 2797 miles of railways in operation within the state, of which the principal lines in point of mileage were the Chicago, Milwaukee, and St Paul, the Chicago and North-Western, the Great Northern, the Burlington and Missouri, the Fremont, Elkhorn, and Missouri Valley, and the Chicago, St Paul, Minneapolis, and Omaha.

Finance.—The total assessed value of property in the state in 1898 was $120,175,431, which yielded state taxes to the amount of $478,881. The state debt in 1898 (1st July) was $861,600. The state banking law is modelled after the United States Banking Act. There are 25 national banks, with deposits of $5,330,951 and a capital of $1,460,000; 109 state banks, with deposits of $5,322,384 and a capital of $1,245,227; and 70 private banks, with deposits of $3,329,486 and a capital of $945,076.

Population.—The census of 1890 gave the population of South Dakota alone as 328,808, being an increase during the preceding ten years of 234·6 per cent. In 1900 the population was 401,570, an increase for the decade of 72,762, or 22·1 per cent., approximately that of the country as a whole. The average number of persons to the square mile was, in 1900, 5·2, as compared with 4·3 in 1890. There were, in 1900, 134 incorporated cities, towns, and villages in South Dakota, of which 25 had more than 1000 inhabitants, 12 more than 2000, and only 2 more than 5000. These two were Sioux Falls, with 10,266, and Lead City, with 6210 inhabitants. The capital, Pierre, had 2306 inhabitants. The death-rate of the entire state in 1900, on the basis of the number of deaths reported to the census enumerators in that year, was about 7·7. Of the total population in 1900, 216,164 (53·8 per cent.) were males and 185,406 females; 313,062 (78 per cent.) were native-born and 88,508 foreign-born; 380,714 (94·8 per cent.) were white and 20,856 were coloured, of whom 465 were negroes, 165 Chinese, 1 Japanese, 20,225 Indians. Although there are numerous settlements of Scandinavians, Germans, Dutch, Bohemians, and other nationalities, the American element is being rapidly increased by the immigration of farmers from Iowa, Wisconsin, Illinois, and other states, who, having sold their farms at high prices, go west to buy equally good lands at a cheaper rate. Great numbers of Indians have abandoned their tribal relations and are taking their lands in severalty.

History and Politics.—The state formed a part of the Louisiana purchase, and a portion of it was at one time included in Minnesota territory, and later formed a part of the territory of Nebraska. The territory of Dakota was organized in 1861, and included the present states of North and South Dakota and a large portion of Wyoming and Montana. It contained less than 5000 white inhabitants. In 1870 that part of the territory that is now the state of South Dakota contained 11,776, and in 1880, 98,268, an increase for the decade of 734·5 per cent. The first constitutional convention met at Sioux Falls in October 1883, and drafted a state constitution, which was adopted by the people and presented to Congress for approval; but no action was taken. On 22nd February 1889 Congress passed an Enabling Act, under which South Dakota was admitted as a state, 3rd November 1889. The former large Indian reservations west of the Missouri river have been subdivided and large portions thrown open to settlement.

The state is Republican in politics, but was carried for Mr Bryan and the Populist ticket in 1896 by a majority of a few hundreds, and in 1898 a Populist governor was elected by a small majority, though the Republican Congressmen and the balance of the state ticket were elected by a large one. In 1900 the state went Republican by a plurality of 14,986. Three important amendments to the constitution were submitted to the voters at the election of 1898. One of them, involving the initiative and referendum systems of legislation, was adopted by a majority of 7331; another, involving women's suffrage, was defeated by a majority of 3285; and the third, involving

the dispensary liquor system founded on that of South Carolina (see LIQUOR LEGISLATION), was adopted by a majority of 1643; the Legislature of 1898–99, however, instead of enacting any legislation to put the amendment in force, passed a resolution submitting to the voters its repeal, which was carried in the election of 1900. The civil and penal codes, as well as civil and criminal codes of procedure, are similar to those adopted in California, and are founded on those favourably reported by the Code Commissioners of New York. (B. T.)

South Easton, a former borough of Northampton county, Pennsylvania, U.S.A. It is on the south bank of the river Lehigh, at its mouth, opposite Easton, on the Lehigh Valley Railroad. It is situated mainly on the summit of the river cliffs, here 100 feet or more in height. Population (1880), 4534; (1890), 5616. In 1890 it was annexed to Easton.

Southend-on-Sea, a municipal borough (incor porated 1892, extended 1897) and watering-place in the south-eastern parliamentary division of Essex, England, on the estuary of the Thames, 35 miles east of London by rail. A commission of the peace was granted to the borough in 1894. Modern buildings are a church, a theatre, and a large hall. There are a marine park of 26 acres, several pavilions, a revolving tower, and other attractions. Southend has considerably extended towards the west, and a new and handsome suburb, Westcliffe, now adjoins it on that side. Westcliffe has a railway station on the London and Tilbury line, several hotels, and many pretty villas, commanding delightful views of the mouth of the Thames and the opposite county of Kent. Population (1881), 7979; (1901), 28,857.

South Framingham, a village in the town of Framingham, Middlesex county, Massachusetts, U.S.A. It is in the eastern part of the state, at an altitude of 163 feet, at the intersection of the main line of the Boston and Albany with a line of the New York, New Haven, and Hartford Railroad.

South Georgia, an uninhabited British island in the South Atlantic, about 900 miles south by east of the Falklands, 54°–55° S. and 36°–38° W.; area, 1600 square miles. It is mountainous, with snowy peaks 6000 to 8000 feet high, their slopes furrowed with deep gorges filled with glaciers, which in some places descend to sea-level. Its geological constitution—gneiss and argillaceous schists, with no trace of fossils—shows that the island is, like the Falklands, a surviving fragment of some vanished continent, most probably indicating a former seaward extension of the Andean system. At Royal Bay, on the south-east side, was stationed the German expedition sent out to observe the transit of Venus in 1882. The slopes being covered with succulent herbage (tussock grass), the island would be well suited for cattle or sheep farming but for its damp, foggy climate, with a mean annual temperature of 34° or 35° F., seldom rising to 66°, but falling in winter to 9° or 10°. Yet, regard being had to the conditions, the flora is surprisingly rich, and the German naturalists were able to collect thirteen flowering plants, mostly common also to the Falklands, but one allied to a form found in distant New Zealand. South Georgia is politically attached to the Falklands.

Southington, a town of Hartford county, Connecticut, U.S.A. It is near the centre of the state, mainly in the valley of Quinnipiac river, and extending to the hills on either side. Within its area of 38 square miles is a borough of the same name, located on the river, at an altitude of 149 feet and on a line of the New York, New Haven, and Hartford Railroad. Its manufactures consist largely of cutlery and other metal goods. Population of the town (1890), 5501; (1900), 5890; of the borough (1900), 3411, of whom 790 were foreign-born.

South McAlester, a city of the Choctaw Nation, Indian Territory, U.S.A. It is near the centre of the territory, at the intersection of the Missouri, Kansas, and Texas and the Choctaw, Oklahoma, and Gulf railways, at an altitude of 716 feet. Near it, on the east and west, are the valuable coal-mines of Indian Territory, and its prosperity is in great part due to the handling and shipping of coal. Its inhabitants consist almost entirely of whites, as the Indians remain aloof from the railroad. Population (1900), 3479, of whom 119 were foreign-born, and 621 coloured, including 592 negroes.

South Norwalk, a city and seaport of Fairfield county, Connecticut, U.S.A. It is at the mouth of the river Norwalk, and on the New York, New Haven, and Hartford Railroad, in the south-western part of the state. The site rises from the water, and beautiful villas have been built upon it. Its harbour is good, and there is regular steamer communication with New York and other Sound ports. Population (1880), 3726; (1890), 6152; (1900), 6591, of whom 1528 were foreign-born.

South Omaha, a city of Douglas county, Nebraska, U.S.A. It is on the west bank of the Missouri, immediately adjoining Omaha on the south, at an altitude of 1124 feet. It is entered by seven railways. Next to Chicago and Kansas City, it is the greatest slaughtering and meat-packing centre in the United States, containing several large packing-houses and immense stock-yards. In 1900 it had 109 manufacturing establishments, with a capital of $16,471,329, employing 6606 hands, and with a product valued at $70,080,941. Of this product no less than $67,716,724 was wholesale slaughtering and meat packing. It was chartered in 1885. Population (1890), 8062; (1900), 26,001, of whom 5607 were foreign-born and 571 negroes. There were 8106 persons of school age (5 to 20 years). Of 9880 males 21 years of age and over, 205 were illiterate (could not write).

South Orange, a township and village of Essex county, New Jersey, U.S.A. It is on the river Rahway, and on the Delaware, Lackawanna, and Western Railroad, in the north-eastern part of the state, at an altitude of 142 feet. It is 15 miles west of New York City, of which it is in great measure a residential suburb. It has a beautiful situation on Orange mountain, and contains many fine residences. Population of the village (1900), 4608; of the township, exclusive of the village (1900), 1630. Of the population of the village in 1900, 1140 were foreign-born.

Southport, a municipal borough and seaside resort in the Southport parliamentary division of Lancashire, England, 18½ miles north of Liverpool by rail. Modern erections are the Victoria Science and Art School, an infirmary, and additions to the convalescent hospital. A marine park was laid out in 1887; a marine carriage drive and a recreation ground were provided in 1895. Area (1891), 3665 acres. Population (1891), 41,406. In 1900 the area was extended to 9093 acres. Population (1901), 48,087.

South Portland, a city of Cumberland county, Maine, U.S.A. It is on Portland harbour, and on the Boston and Maine Railroad, in the south-western part of the state. It has been formed from a part of Cape Elizabeth Town. Population (1900), 6287, of whom 763 were foreign-born.

Southwell, a parish, city, and township in the Newark parliamentary division of Nottinghamshire, England, 14 miles north-east of Nottingham by rail. The cathedral church of St Mary, founded in 630 by the first archbishop of York, is a magnificent cruciform building, mainly Norman, but partly Early English in style, with some Perpendicular insertions. In 1882 it was thoroughly restored at an expenditure of about £20,000. The ancient palace of the archbishops of York, now partly ruinous, adjoins the churchyard of the minster, and in 1882 its "great chamber" was restored. The episcopal see of Southwell was founded in 1884. The city has lace and silk factories. The racecourse was closed in 1898, owing to its dangerous condition. Population (1881), 2866; (1891), 2831; (1901), 3160.

South-West Africa, German.—This German possession covers roughly the region formerly known as Damaraland and Namaqualand. The coast in its entire length of about 800 miles has no good harbour, and those ports which exist—Angra Pequeña, Sandwich Harbour, Walfish Bay—are gradually being filled with sand by the strong, cold, northerly coast current. Only Swakopmund, where proper precautions are taken, is likely to escape this fate. The coast-line is bordered by a belt of sand-dunes and desert, which in the south is about 35 miles wide and narrows towards the north. On the east this coast belt is flanked by a mountain range, which attains its highest elevation in Mount Omatako (8500 feet). These mountains form the escarpment of the great Kalahari plateau, which, gently rising from the interior towards the coast, slopes again towards the south and north from the point of its highest elevation. The Kalahari plateau changes the undulating character which it has in the west to a perfect plain in the far east, where the habitable country, with water, merges into the sterile Kalahari desert. There are only two important rivers found in South-West Africa, which do not entirely belong to the hydrographic system of the country. The Cunene comes from the Portuguese colony of Angola, and for a short distance forms the northern boundary of the colony; the Orange river, which forms the entire southern boundary, is the recipient of all the rivers of the protectorate which have a southerly direction. The Cunene and Orange have water all the year round, but are not navigable. The Okovango, which comes from the north and runs into Lake Ngami, is also perennial, but, like the other two rivers, belongs only partly to the hydrographic system of the country, receiving the rivers which take a northerly course. All the other streams of the protectorate, especially those running westwards, have water only after heavy rain, and only in exceptionally rainy years do they carry it on to the ocean. It mostly disappears in the sand which fills the river-beds, and there the water may be obtained by digging. The chief rivers are the Great Fish river and the Oub and Nosob, which, together with another eastern branch, form the Malopo. Both join the Orange. The Okavango receives the Omuramba and Umatako; the Kuisip and Swakob flow into the Atlantic. Hot springs are frequent, and it is remarkable that those of Windhoek flow more copiously during the dry than the rainy season.

Physical features.

On the coast the mean temperature is low, and there is little rainfall. The necessary moisture is supplied by dense fogs, which rise almost daily. South-west winds prevail. The interior enjoys a luxurious climate, with bracing, clear atmosphere. There are considerable differences of temperature between day and night, and two well-marked seasons, one cold and dry from May to September, the other hot and rainy from October to April. In winter ice frequently forms during the night on open water on the plateau, but it never remains all day. The yearly rainfall is not great; there is more in the north than in the south, and in the east than in the west, so that the north-east part of the protectorate is probably that with the most abundant atmospheric precipitation. Only here malarial fevers sometimes occur.

Meteorology.

The vegetation corresponds exactly with the climate. In the dry littoral region we find plants able to exist with the minimum of moisture they derive from the daily fog—*Amarantacea, Sarcocaula, Aloe dichotoma, Aristida subacaulis,* and the wonderful *Welwitschia.* Farther inland we can distinguish between those plants which spring up and disappear with the rain and those whose roots reach permanent water. The former are chiefly grasses, the latter exist almost solely in or near river-beds. Amongst the truly fine trees often seen here, the Ana tree (*Acacia albida*) is the most noteworthy, its seeds being favourite fodder for all domestic animals. *Acacia giraffæ, Ac. horrida, Adansonia sterculia,* near the Cunene the *Hyphæne ventricosa,* deserve special notice. Large game, which was formerly abundant, especially pachyderms, is scarce now. Of antelopes the following species are still plentiful in parts: springbok, steenbok, kudu, rietbok, pallah; of monkeys, the *Cynocephalus porcarius* is frequent. Various kinds of hyænas and jackals with fine fur (*Canis mesomelas*), also *Felis caracal,* abound. The spring-hare (*Pedestes caffer*) and rock-rabbit (*Hyrax capensis*) may often be observed by the traveller. Of birds there are 728 species. Crocodiles, turtles, and snakes are frequent.

Flora and fauna.

Among the coloured inhabitants of South-West Africa three classes may be distinguished. Of the Hottentot and Bushmen, the former probably came from the south, while the latter, together with the second class, the Mountain Damara, may be looked upon as indigenous races. The third class belongs to the Bantu stock, and came from the north-east, expelling and enslaving the Mountain Damaras, and settling in various parts of the country under different names. The most prominent are the Herero, thorough nomads and cattle-breeders; while the Ovambo or Ambo, in the northern part of the protectorate, are agriculturists. The Herero waged long wars with the Hottentots, who are divided into twelve tribes under as many chiefs. One of them, Hendrik Witboy, was the inveterate enemy of the Herero; then turned against the German administration, whose friend and ally he afterwards became. The Bastards are a small tribe originating from a mingling of Cape Boers with Hottentots. They are all Christians, able to read and write, and probably destined to play a part in the future of the colony.

Ethnology.

South-West Africa was annexed on 7th August 1889, when the German flag was raised in Lüderitz Bay. Its northern boundary is the Cunene river and a strip of Portuguese territory, as arranged by agreement of December 1886. From the mouth of the Cunene the boundary goes along to the rapids which this river forms on cutting through the Serra Cama; thence along the parallel of that locality until it reaches the Kubango, following this river to a spot called Andara, which remains on the German side, and thence straight to the Catima rapids of the Zambezi. The west boundary is the ocean from the mouth of the Cunene to that of the Orange river; the territory of Walfish Bay forms a small British enclave of little importance. The south and east boundaries, according to agreement of 1st July 1890, runs as follows:—From the mouth of the Orange river along its northern bank to where this is struck by 20° E. Thence along the meridian to its point of intersection with 22° S. Along that parallel to where it cuts 21° E.; it follows that till it reaches 18° S., along which it continues as far as the Chobe, following the valley of that river to its confluence with the Zambezi. The area thus enclosed measures about 322,450 square miles. The population is estimated at 200,000, 125,000 of whom are Bantu. The European population in 1900 numbered 3388, of whom 2104 were German, besides military.

Boundaries, area, population.

German South-West Africa is divided into three districts, Keetmanshoop, Windhoek, and Otyimbingue. In each of these is a *Bezirksamtmann,* with his staff of officials and a small police force. Each district has a number of small stations, where a non-commissioned officer with a few men keeps the natives in order. In each district is a law court, to whose jurisdiction not alone the whites but also the Bastards are subject. As in all German colonies, there is a court of appeal at the residence of the governor. In Keetmanshoop there is a mining department to register claims and to grant mining licences. The armed force consists of about 1000 regular troops and a militia formed of Bastards. The *Landeshauptmann* is the chief administrator and commander of the forces.

Government.

With the exception of the Bastards, the natives are all pagans. The Rhenish Missionary Society is doing good service on eight stations and the Finnish Mission on five stations in the northern part of the country.

The revenue of South-West Africa is small, and the empire has to pay a considerable subsidy. The revenue for 1901 was 10,452,000 marks, inclusive of an imperial contribution of 9,103,000 marks; expenditure, 10,452,000 (£527,600). The sale of land is progressing favourably, and the growing number of European settlers causes a corresponding increase of imports.

Revenue.

Various taxes exist in those parts of the protectorate where Government authority has been thoroughly established. On articles of export, such as feathers and hides, 5 per cent. *ad valorem* duty has to be paid; on cattle and horses, an export tax per head. The sale of spirituous liquors is subject to a licence, and travelling traders pay for each waggon, cart, or horse they employ.

Shipping. There is regular steamship communication between Hamburg and Swakopmund. The Woerman line despatches a steamer once in two months, which calls at Swakopmund, Walfish Bay, and Lüderitz Bay. A small steamer plies regularly between the coast harbours. A sailing vessel leaves Cape Town regularly once in six weeks, and calls at Lüderitz, Walfish Bay, and Swakopmund. A small schooner sails between Cape Town and Lüderitz Bay only, and a steamer calls about once a month at Walfish Bay and Lüderitz Bay.

Roads, post, and telegraph. A narrow-gauge railway is in course of construction between Swakopmund and the interior, of which about 180 miles were open for traffic at the end of 1901. The existing roads have been considerably improved. On several spots wells have been dug, to enable transport riders to rest their cattle where formerly want of water made forced marches necessary. The construction of water reservoirs or dams is progressing steadily. Across the Awas mountains a wide road has been cut. The protectorate is within the Postal Union, and there is a post office in every larger settlement. From Warmbad runners carry mails once a fortnight to the nearest post office in Cape Colony. From Windhoek a mail cart goes to Swakopmund, and thence either *viâ* Cape Town with the English mail or direct to Hamburg with the Woermann steamer. There is no telegraphic communication with South-West Africa. Telegrams are received at Cape Town and forwarded by ordinary mail.

Production, industry. The products are chiefly animal. The scarcity of water in the southern parts is not favourable for agricultural pursuits, while the good grazing lands offer splendid pasturage for cattle, which the Herero raise in numbers amounting to many hundred thousands. A flourishing cattle trade with Cape Colony existed before the rinderpest. Hides form a valuable export article; also feathers and horns. Sheep thrive well, and are beyond doubt the stock of the future. Goats also answer well. Horses have been imported from the Cape. Unfortunately, the climate does not suit them everywhere, and they are subject to a virulent distemper. Cattle and sheep also suffer from the diseases which are common in the Cape Colony. Camels have been imported, and are doing well. Vegetable products are scarce; agriculture is only carried on in the north, and the products—maize, sorghum, &c.—reach the south only in small quantities; near the coast the natives collect the kernels of the nara, a wild-growing pumpkin; they are exported to Cape Town. Minerals, especially copper, are plentiful in the country, but cannot yet be exploited owing to want of labour, cheap means of transport, and water. Of native industry there is next to nothing. A little pottery is carried on, and the women are clever in making fur cloths. In the north the Ovambo do a little smith-work and grass-plaiting. The imports in 1900 were valued at 6,968,400 marks and exports 907,600 marks. The chief exports are guano and ostrich feathers.

History. When South-West Africa was annexed, only a few mission stations existed, and a few white traders and hunters wandered through its wilds. Since then a considerable number of settlements have sprung into life, of which the most important is Windhoek, the seat of the *Landeshauptmann*, established on the old site of Jonker Afrikander's residence; and little Windhoek, a purely agricultural settlement, where the growth of the grape from the Cape promises every success. In the beginning the natives were hostile, and Hendrik Witboy strenuously opposed German rule. After a protracted war he was subdued, and became a firm ally of the authorities. Safety of life and property was thus secured throughout the country. Many companies, some of them British, have been formed. Private settlers are increasing, and they are recruited mostly from the men who have served their term in the colonial force and have had every chance of judging for themselves the resources of the country. In 1895 there were 13 trading firms, in 1898, 98.

Southwold, a municipal borough and watering-place of Suffolk, England, in the Northern, or Lowestoft, parliamentary division, 12 miles south-south-west of Lowestoft, with a station on a single line connecting with the Great Eastern at Halesworth. The church of St Edmund's (Perpendicular) is an ancient flint structure. Herrings, sprats, smelts, and shrimps caught here are sent to the London market. A lighthouse was erected in 1890 on the North Cliff. In 1900 a pier 270 yards long was constructed, and serves as a calling-place for pleasure steamers, and the corporation has expended large sums in the improvement of the sea front. A fine common to the south of the town is used for golf, lawn-tennis, cricket, and other sports. Population (1891), 2311; (1901), 2800.

Sovereignty.—The word sovereignty is said to be derived from the mediæval word *supremitas, i.e., suprema potestas.* (See Skeat's *Etymological Dictionary* as to various forms of the word, and Meyer, *Lehrbuch des Deutschen Staatsrechts*, 15, as to its derivation.)

Sovereignty may be viewed in three ways: there is the historical explanation of its origin and growth, its rude beginning in the savage horde, its completion in the modern state; there is the analytical or juridical explanation; there is also what (for want of a better phrase) may be called the organic explanation of sovereignty.

History. The following are some of the chief stages in the history of sovereignty:—While society is in a rude state or only tribally organized, there is no distinct sovereignty, no power which all persons habitually obey. Thus there is no sovereignty among wandering groups of Australian savages: each family is isolated; each horde is a loose and unstable collection. When the horde has become a tribe, there may exist no definite sovereign. Distinct in time of war, the power of the chief may be fluctuating and faint in time of peace; even in time of war it may be subject to the authority of a council. Tribes of the same ethnic stock may form a sort of federation, permanent or temporary. "With the council of the confederacy," it has been said, "and, more generally, in the confederacy, sovereignty arises and the true political tradition is evolved" (Giddings, *Principles of Sociology*, p. 285). When the city and the State are conterminous, the seat of sovereignty becomes defined. Such was the condition of things in Greece, as considered by Aristotle in his *Politics.* He discusses the question what is the supreme power in the State (3. 10), which he defines as an aggregate of citizens (3. i.), and he recognizes that it may be lodged in one, a few, or many. In his view, the distinctive mark of the State is not so much sovereignty (7. 4) as self-sufficiency; a State is not a mere aggregate of persons; it is a union of them sufficient for the purposes of life (7. 8); sufficiency being "to have all things and to want nothing" (7. 5. 1). The Roman jurists say little, and only incidentally, as to sovereignty. But in the Middle Ages, under the influence of the Roman law, and with the belief in the existence of an empire entitled to universal sway, an absolutist theory of sovereignty was developed in the writings of the jurists who revived the study of that law: the emperor was sovereign; "quod principi placuit legis habet vigorem" (*Institutes*, i. 2. 6).

Those jurists often justified the *plenitudo potestatis* conceded to the emperor by the fact that he stood at the head of Christendom. Among the theories prevalent in the Middle Ages was one that mankind formed a unity, with the pope and the emperor at the head of it: the universal Church and the universal emperor ruled the world. Even to Leibnitz, writing in the 17th century, it seemed that "totam Christianitatem unam velut Rempublicam componere, in qua Cæsari auctoritas aliqua competit" (*Opera*, 4. 330). When the power of the emperor was weakened, and the idea of a universal ruler was gone, a new test of sovereignty was applied—that of external independence; the true sovereign States were *universitates superiorem non recognoscentes.* There were

times and countries in the Middle Ages in which the collective power of the community was small: many of the great corporations were virtually autonomous; the central authority was weak; the matters as to which it could count upon universal obedience were few. In such circumstances the conception of sovereignty was imperfect. It has been suggested that the modern conception of it was evolved from the contest between three powers: the Church, the Roman Empire, of which the individual States in Europe were theoretically provinces, and the great landowners and corporations. Whatever may be the truth as to this, the modern theory is first clearly stated in Jean Bodin's book *On the Commonwealth* (French edition, 1576; Latin version, 1586), which was the first systematic study of sovereignty. Bodin defines the State thus: "Respublica est familiarum rerumque inter ipsas communium, summa potestate ac ratione moderata multitudo." His theory, which corresponded on the whole to the state of things in France in the time of Louis XI., was a theory of despotism. It may be also described as a type of the mechanical or juridical theory of sovereignty. According to Bodin, there is in the State unlimited one power: "Majestas est summa in cives ac subditos legibusque soluta potestas" (i. p. 8). There exists a central force from which are derived all the powers which make or give effect to laws; a power which he describes sometimes as "majestas summa potestas summum imperium." This was the conception expressed by Bossuet, "Tout l'état est en la personne du prince," or in Louis XIV.'s saying, "L'état c'est moi."

One favourite theory was that sovereignty originated in a social contract. It was assumed that the individual members of society, by express or implied pact, agree to obey some person or persons; sometimes it is described as an unqualified handing over; sometimes it is a transfer subject to qualifications, and with notice that in certain contingencies this will be withdrawn. Gierke, in his book *Johannes Althusius und die Entwickelung der Naturrechtlichen Staatstheorie*, shows (p. 76) that the conception of a treaty or agreement as the basis of the State was in the Middle Ages a dogma which passed almost unchallenged, and that this theory was maintained up to a late period. It is to be found in the writings of Thomas Aquinas (*de Regimine Principum*, 266), Marsillus of Padua, Buchanan, Mariana, and Suarez. It is the kernel of the theories of Hobbes, Rousseau, Filmer, and Locke. Among the clearest and most logical exponents of this theory was Hobbes, who in his *Leviathan* expounded his notion of an agreement by which absolute power was irrevocably transferred to the ruler. Puffendorf, with some variations, states the same theory. In his view there is a *pactum unionis*, followed by a *pactum subjectionis*. The best-known exponent of this theory of the source of sovereignty is Rousseau, who assumes the existence of a *pacte social*, the terms of which are: "Chacun de nous met en commun sa personne et toute sa puissance sous la suprême direction de la volonté générale; et nous reçevons encore chaque membre comme partie indivisible de tout" (*Du Contrat Social*, 1. c. 6).

Those who distinguish society from the State, and who see in the latter only one of a group of institutions included in the former, do not regard sovereignty in any of the above lights. The tendency of students of sociology is to give little prominence to sovereignty, and to treat it as an incident of a highly organized society. Comte, Spencer, Bagehot, Durkheim, and Giddings, for example, refer to it, if at all, only briefly and incidentally; they conceive society as an organism, or at all events as a growing whole, no one part or force being the cause of all others, and all interacting; society is not the product of any agreement or of force alone, but of a vast variety of interests, desires, and needs. Not the State or Government comes at a certain stage of organization: small groups are drawn together; powerful corporations fall into line; a national feeling develops; eventually the State as we know it is formed. Sovereignty is a resultant of many forces. It may not exist as to some regions of conduct; as to others it may be weak and mutable; only in certain conditions is the sovereign power supreme as to all matters of conduct.

Among the different senses in which "sovereign" has been used are the following:—

(*a*) "Sovereign" may mean titular sovereign—the King in the United Kingdom, the Kaiser in Germany.

(*b*) The legal sovereign: the person or persons who, according to the law of the land, legislate or administer the Government.

(*c*) The political or constitutional sovereign: the body of persons in whom the actual power at any moment or ultimately resides. Sometimes this is designated "the collective sovereignty."

(*d*) Sovereignty is also used in a wider sense as the equivalent of the power, actual or potential, of the whole nation or society (Gierke, 3. 568).

The distinction between real and nominal sovereignty was familiar to mediæval writers, who recognized a double sovereignty, and distinguished between (1) the real or practical sovereignty resident in the people, and (2) the personal sovereignty of the ruler. (Adolf Dock, *Der Souveranitätsbegriff*, &c., p. 13.) By many writers sovereignty is regarded as resident not in any one organ, but in the *Gesammtperson* of the community (Maitland, *Political Theories of the Middle Ages*, xliii.).

Sometimes sovereignty is defined as the organized or general will of the community (Combothecra, *Conception Juridique de l'État*, p. 96). "Sovereignty is the organized will of an organized independent community. . . . The Kings and Parliaments who serve, as its vehicles." "Sovereignty resides in the community" (Woodrow Wilson, p. 1448). The same theory is often expressed by saying that the majority in a community, or a particular group, in fact, rules (Guizot, *Representative Government*, i. p. 167). This was the doctrine of the French Revolution. "Sachez que vous êtes rois et plus des rois," said a revolutionary orator cited by Taine. It was the language of the founders of the American Constitution and contemporary political writers; the language, for example, of Paine: "In republics such as there are established in America the sovereign power, or the power over which there is no control and which controls all others, remains where nature placed it—in the people" (*Dissertations on Government*, i. 6).

The same theory assumes a more subtle form, especially in the writings of Hegelians. Sovereignty is with them a term descriptive of the real will of the community, which is not necessarily that of the majority. "If the sovereign power is to be understood in this fuller, less abstract sense, if we mean by it the real determinant of the habitual obedience of the people, we must look for its sources much more widely and deeply than the analytical jurists do; it can no longer be said to reside in a determinate person or persons, but in that impalpable congeries of the hopes and fears of a people bound together by common interest and sympathy, which we call the common will" (Green's *Works*, 2. 404). "Though it may be misleading to speak of the general will as anywhere, either actually or properly, sovereign . . . yet it is true that the institutions of political society are an expression of, and are maintained by, the general will" (2. 409).

Sovereignty is used in a further sense when Plato and

Aristotle speak of the sovereignty of the laws (*Laws*, 4. 715; *Politics*, 4. 4; 3. 15). Thus Plato remarks: "I see that the State in which the law is above the rulers, and the rulers are the inferiors of the law, has salvation." (See also Gierke, *Genossenschaftsrecht*, 3. 8.) Even in mediæval writers such as Bracton is found the notion that the king is subject to the laws: "Bracton knows of no sovereign in the Austinian sense, and distinctly denies to the royal authority the attribute of being incapable of legal limitation" (Figges, *The Divine Right of Kings*, p. 13). We find the same expressed by many German jurists, *i.e.*, the idea of a State which exists only in the law and for the law, and whose life is but by a legal order regulating public and private relationship (Gierke, iii. x.).

Definitions of sovereignty.

Among the definitions of sovereignty may be quoted these: "That which decides in questions of war and peace, and of making or dissolving alliances, and about laws and capital punishment, and exiles and fines, and audit of accounts and examinations of administrators after their term of office" (Aristotle, *Politics*, 4. 4. 3). "Suprematum illi tribuo qui non tantum domi subditos manu militari regit, sed et qui exercitum extra fines ducere et armis, fœderibus, legationibus, ac cæteris juris gentium functionibus aliquid momenti ad rerum Europæ generalium summam conferre potest" (Leibnitz, *Opera*, 4. 333). "La souveraineté est celle qui sert a exprimer l'independance d'un état aussi bien à l'intérieur qu'à l'extérieur" (De Martens, *Traité du Droit International*, translated by A. Leo, 1881, i. 378). "L'independance complete qui peut se manifester à deux points de vue; l'un extérieur, l'autre intérieur" (M. Despagnet, *Droit International Public*, 1894, p. 80). "Sovereignty as applied to States imports the supreme, absolute, uncontrollable power by which any State is governed" (Cooley, *Constitutional Limitations*, p. 1). "Social control, manifesting itself in the authoritative organization of society as the State, and acting through the organs of Government, is sovereignty" (Giddings, *Elements of Sociology*, p. 217). See the collection of definitions in *Der Souveranitätsbegriff im Bodin*, &c., by Dr Adolf Dock (1897), p. 6, and in *La Conception Juridique de l'État*, by Combothecra, p. 90). Many of these definitions describe an ideal state of things rather than realities. Some of the definitions would apply to the authority of powerful religious bodies in certain periods of history, or of illegal associations, such as the Mafia, which have terrorized the community.

Territorial sovereignty is used in a variety of senses. Often the phrase is the equivalent of sovereignty. It may mean a state of things such as existed in the Middle Ages, in which ownership and sovereignty were not clearly separated: when he who was owner had sovereign rights incident thereto, or, as it was sometimes phrased, when sovereignty inhered in the territory, when the king was the supreme landowner (Maine, *Ancient Law*, 106); when all political power exhibited proprietary traits, and was incident to the ownership of land (Maitland, *Township and Borough*, 31). Territorial sovereignty is thus defined by Leibnitz: "Superioritatem territorialem in summo subditos coercendi jure consistere" (*Opera*, 4. 358. See Laband, 1. c. 8).

Nature of sovereignty.

Certain propositions are often stated with respect to sovereignty. One of them, stated by Rousseau (*Du Contrat Social*, 2. c. 2), is that it is indivisible: a proposition true in the sense that in regard to the same matters at the same time there cannot be two sovereigns, but not true in the sense in which it has often been employed, namely, that in the last analysis of society there are some persons or person who controls all conduct and are habitually obeyed as to all matters. Rather we may say with Maine, "Sovereignty is divisible, but independence is not." A frequent deduction from the theory of the indivisibility of sovereignty is that there cannot be double allegiance; in other words, no one can be the subject of two States. This deduction is not in fact true. With the existing differences in the laws of modern States as to nationality, persons may be, and are, subjects of two or more States. In the native states in India there may be said to be double allegiance. Mr Tupper, in his work on *Indian Protectorates*, refers to "the double allegiance of the subjects of native states" in India; and he explains that the native rulers are themselves subject to the Indian Government. "For all purposes of our relation with Powers the subjects of Indian native states must be regarded as subjects of Her Majesty" (Tupper, *Indian Protectorates*, p. 353). Such double allegiance is apt to exist in times of transition from one sovereignty to another; for example, in the 18th century, in the British possessions in India, the Mogul was said to exercise a personal sovereignty. As Sir William Scott remarked in the *Indian Chief*, 3 C. Rob. 22, it hardly existed otherwise than as a phantom: the actual authority was exercised by the East India Company.

Another deduction from the same proposition is that any corporation or private body which appears to exercise sovereign powers together with the State does so only by delegation. This theory is thus stated by Burke (*Works*, 7. 289) with reference to the East India Company: "The East India Company itself acts under two very dissimilar sorts of power, derived from two sources very remote from each other. The first source of its power is under charters which the Crown of Great Britain was authorized by Act of Parliament to grant, the other is from several charters derived from the Emperor of the Moguls. . . . As to those of the first description, it is from the British charters that they derive a capacity by which they are considered as a public body, or at all capable of any public function. . . . This being the root and origin of their power, renders them responsible to the party from whom all their immediate or consequential powers are derived."

Another proposition often stated with respect to sovereignty, is that it is unlimited: a proposition which is not true of the legal or political sovereign. In all States are limits, more or less definite, to such powers, according to the character of the subjects and the relations of the State to foreign powers. Even despotism is tempered by assassination and the liability of revolution (Dicey, *Law of the Constitution*, p. 73). A third proposition often expressed with respect to sovereignty, is that it cannot be alienated: a proposition thus stated by Rousseau: "Je dis que la souveraineté, n'étant que l'exercise de la volonté générale, ne peut jamais s'aliéner" (*Du Contrat Social*, 2. 1).

According to one view, sovereignty is not the distinctive note of a State. Many communities usually regarded as true States do not possess it. There are sovereign and non-sovereign States; international law recognizing both. In the view of many writers sovereignty is not a necessary attribute of a State, but a mark of independence (Laband, *Das Staatsrecht des Deutschen Reiches*, 1. 87; Jellinek, *Die Lehre von der Staatenverbindungen*, p. 37; Meyer, *Lehrbuch des Deutschen Staatsrechtes*, p. 5; Rehm, *Allgemeine Staatslehre*. See the contrary view presented by Professor Burgess, *Political Science or Constitutional Law*, i. 52; *Political Science, Quarterly*, 3. 123; M. Georges Streit, *Revue de Droit International*, 1900, p. 14).

The phrase *half sovereign States* was invented by J. J. Moser to describe States possessing some of the attributes
